SULPHONAMIDE RASHES

AN ANALYSIS OF 500 CASES SEEN IN NORTH AFRICA AND ITALY

BY

G. A. GRANT PETERKIN, M.B., F.R.C.P.Ed.

Major, R.A.M.C., C.M.F.; Dermatological Specialist; Assistant Physician, Skin Department, Royal Infirmary, Edinburgh

Since 1937 it has been widely realized that the administration of sulphonamides by mouth is liable to cause drug rashes, particularly of a photosensitive type (Goodman and Levy, 1937; Ballenger *et al.*, 1937; Hallam, 1939), but it was not appreciated until recent times that the local application of these drugs could produce reactions as serious and lasting in their effects as those caused by oral administration. At one time I was an enthusiastic user of sulphathiazole on the skin, in the form of 5%-strength in Lassar's paste or in a water-miscible cream (Peterkin and Jones, 1943). With this drug it was found that straightforward septic conditions of the skin such as impetigo contagiosa rapidly vanished. Only two or three cases of sensitization to the sulphonamide group were noted, and they had been treated with sulphanilamide powder before admission to hospital. These reactions soon yielded to soothing applications, so that sulphathiazole, used in this strength and in this form, was regarded as less liable to cause disagreeable reactions than such well-tried drugs as mercury.

In an active theatre of war, however, sulphonamides are used to a far greater extent than in military or civil life at home, and the relative proportion of individuals being treated with these drugs (for wounds, burns, and septic conditions) is very much higher. There is therefore far more risk of sensitization, and many more sulphonamide rashes tend to be observed abroad, though it is interesting to note that the incidence in North Africa and Italy seemed to be much higher than in the Middle East (Park, 1943; Tate and Klorfajn, 1944a, 1944b).

Since my arrival in North Africa in Feb., 1943, I have been compelled in no uncertain fashion to revise my original view concerning the use of these drugs as local applications. During my first 10 days in North Africa, of the 25 cases evacuated from the forward areas diagnosed as impetigo, no fewer than 15 were cases of sulphonamide-light dermatitis of a severity I had never seen in the United Kingdom. During the period spent in North Africa (Feb. to Dec., 1943) and in Italy (Jan. to Dec., 1944)—i.e., 23 months—over 650 cases of sulphonamide sensitization have been seen. Careful notes have been kept of 500 of these cases.

Under active service conditions it is difficult to obtain access to current literature, but it is believed that so far no paper has appeared describing a considerable number of sulphonamide eruptions and attempting to classify them into various groups, though the book by Bertin and Huriez (1942) must be mentioned as well as the paper by Pillsbury (1944).

Many authors have described cases of the different types of reaction due to the sulphonamides. Shaffer (1943) mentions "contact-type" dermatitis with often widespread vesicular lesions and exacerbation of the original disease, and also refers to scarlatiniform, morbilliform, urticarial, purpuric, vesicular, pemphigoid, pustular, and furunculoid eruptions, as well as rashes closely resembling erythema multiforme, erythema nodosum, and exfoliative dermatitis. Miescher (1943) notes a type composed of erythematous spots on the extremities, especially the extensor surfaces (and sometimes on the face), ranging in size from a lentil to about 2 sq. in.—not sharply defined but slightly infiltrated. The first mention of the fixed type of drug eruption (somewhat like a phenolphthalein rash) seems to have been made by Loveman and Simon (1939). Costello *et al.* (1942) noted that 21 of 196 cases treated with sulphathiazole developed skin eruptions, erythema nodosum, scarlatiniform, urticarial, and papular rashes, and angioneurotic oedema.

The photosensitization types come into a different group; they seem to be far less common in the United States than in Britain, and very few cases occurred in American soldiers serving over-seas. Despite a close liaison with three U.S. dermatologists, I saw only 5 cases in their patients, though the incidence among Canadian soldiers was as high as in British troops (Hair, personal communication). Sulphonamides were used, if anything, more freely in American patients, but sulphadiazine was more often prescribed than sulphanilamide or sulphathiazole.

Of the various drugs employed, sulphanilamide seemed the most apt to cause reactions, especially if used in the form of the powder, but sulphathiazole, sulphapyridine, sulphadiazine, and sulphaguanidine were often the agents used. The whole group were less likely to cause reactions if applied in the form of a thick paste or a water-miscible cream. In over 90% of cases the original drug which had sensitized the skin was sulphanilamide powder.

Types of Eruption seen in B.N.A.F. and C.M.F.: 500 Cases

	Cases	%
I. Sulphonamide-light	361	72·2
(*a*) Erythemato-papular	47	9·4
(*b*) Vesicular	1	0·2
(*c*) Severe—bullous, crusted, and oedematous	309	61·8
(*d*) Telangiectatic	4	0·8
II. Contact: Vesiculation, followed by weeping and superficial ulceration; maybe general eczematization	51	10·2
III. Infectious eczematoid dermatitis, following a contact dermatitis	31	6·2
IV. Disseminated neurodermatitis—maybe secondary to a patch of neurodermatitis	4	0·8
V. Generalized vesicular	4	0·8
VI. Generalized bullous (pemphigoid)	1	0·2
VII. Fixed type of drug eruption	1	0·2
VIII. Purpuric:		
(*a*) Generalized—after oral administration	1	0·2
(*b*) Contact—purpuric reaction	3	0·6
IX. Morbilliform: Often with vesico-bullous eruption of hands and feet	12	2·4
X. Scarlatiniform	3	0·6
XI. Urticarial	3	0·6
XII. Lupus erythematosus	5	1·0
XIII. Erythema multiforme	6	1·2
XIV. Erythema nodosum	5	1·0
XV. Pustular or acneform	4	0·8
XVI. Exfoliative dermatitis	5	1·0

I. Sulphonamide-Light Eruption

(*a*) *Erythemato-papular Type.*—This was the first type of reaction recognized as being due to the sulphonamides, and has been described by Goodman and Levy (1937), Ballenger *et al.* (1937), and Hallam (1939), among others. More recently, excellent descriptions of cases occurring in the Middle East have been given by Park and Platts (1942) and Park (1943).

This eruption may be seen in patients after oral medication or local application. Prior to 1941 the former was usually the cause, and was not uncommonly seen in peacetime in people who had been treated with sulphapyridine, followed by general ultra-violet irradiation as a tonic treatment. The typical dusky-red erythemato-papular rash, limited exactly to the areas exposed to light, disappeared spontaneously in 24 to 48 hours, and the patient did not remain light-sensitive. The type due to local application was rarely seen in civil life, but proved to be moderately common in Army dermatology. It was usually associated with a typical sulphonamide contact dermatitis (see below), and disappeared rapidly without treatment; 47 such cases were noted.

Illustrative Case.—Bdr. A., aged 25. First seen on June 22, 1943. He was admitted to a field ambulance with a gunshot wound of the lower left thigh, which had been treated by his R.M.O. with sulphanilamide powder and a shell dressing. For the next three weeks sulphanilamide powder was applied daily; he was then evacuated to the base, as the wound seemed more septic and a dermatitis had appeared. On June 21 a rash broke out on the face, neck, hands, arms, and knees. On examination he had a typical sulphonamide contact dermatitis of the left thigh, with a characteristic erythemato-papular eruption sharply limited to the exposed areas. In 24 hours the rash on the face and limbs had faded, and by July 5 the dermatitis had healed thoroughly.

(*b*) *Vesicular Type.*—Only one case of this kind was observed.

Illustrative Case.—Bdr. B., aged 24; admitted to hospital on Sept. 7, 1943. On Aug. 24 he received a kick on the shin while playing football; a superficial graze resulted. This was dressed at his unit with sulphanilamide powder, which was reapplied daily for seven days. On Aug. 31 he noticed small blisters on the back of the hands, and two days later his hands, face, neck, and knees were covered with hundreds of small blisters. He was sent to hospital as a case of smallpox, as there had been one or two cases in the neighbourhood. On examination the original graze was found healed, with a constellation of vesicles around; these were the size of seed pearls, and were exactly localized to the skin to which the dressing had been applied. The exposed areas of the skin—the face, neck (including the upper sternal area), forearms, hands, and knees—were studded with similar vesicles. These had a non-inflammatory base, were quite discrete, and cultures from them were sterile. Otherwise the skin was healthy except for pityriasis simplex capitis and perlèche. With a soothing and mildly astringent lotion (liq. plumbi subacetat. fort. in calamine lotion) the eruption disappeared in five days, but full recovery was retarded by the appearance of boils on the neck. He was returned to duty on Oct. 10, 1943.

(*c*) *Severe Type—Bullous, Crusted, and Oedematous.*—This was by far the commonest type of sulphonamide rash (309 cases), and accounted for over 60% of the total series. Though not unusual in the U.K., this type seen over-seas was usually of a severity unknown at home. Strong sunlight played its part, yet some of the worst cases were observed in Italy in Jan., 1944, when the weather was extremely cold and bitter, with little sun. It was significant that the syndrome was rarely recognized before the admission of the patient to hospital, the diagnosis usually being "severe impetigo" (often "with cheiropompholyx") or "pyodermia"; thus many unfortunate men were dosed with large quantities of sulphonamide tablets, with deplorable results. A great proportion of the patients were cases of impetigo which had been treated with sulphanilamide powder. The condition is best described by two illustrative cases:

Case 1.—Pte. C., aged 28; admitted Feb. 25, 1944. This patient was a medical orderly in an infantry unit at the Anzio beach-head; from Feb. 14 to 20 his chief duty had been the treatment of wounds with a sulphanilamide insufflator. On Feb. 20 he suddenly developed a crusted, oozing rash which covered his face like a mask, accompanied by a rise in temperature (i.e., a sulphonamide–light eruption). This was diagnosed as an acute impetigo, and he was given sulphanilamide tablets (7 g.) during the 22nd and 23rd. His eyes became inflamed, with intense photophobia; the whole face was swollen, and blisters appeared on the back of the hands. He was then evacuated to hospital. On examination the whole of the face and neck was a confluent crusted mass, with oedema of the eyelids and intense photophobia; the lips were swollen, crusted, and haemorrhagic; the back of the hands and the proximal phalanges were covered with a septic vesico-bullous eruption. Though he had been wearing battledress, the areas exposed in summer (arms, neck, and knees) showed slight desquamation. By March 11 the skin was healed, but still dry and taut. It was gradually exposed to direct sunlight, which caused a slight recurrence on the 20th, after 20 minutes' exposure, but he was able to tolerate full exposure to the sun for several hours by April 12. He was discharged on April 17, able to bare his body to sunlight for the whole day, and was recommended for indoor duties. He had spent 56 days in hospital. He kept well till Aug. 10, when for no apparent reason he had a violent recurrence. He was readmitted to hospital and sent home by hospital ship.

Case 2.—Gunner O., aged 29; admitted on June 2, 1944. In Oct., 1943, this patient had impetigo, which was treated with sulphanilamide powder; he developed a sulphonamide–light eruption, which healed after three weeks, leaving no photosensitivity. In Dec., 1943, he sustained a slight wound of the arm, and, despite his statement that he was "sulphonamide-sensitive," this was treated with sulphanilamide and vaselined gauze (S.V.G.). The usual rash appeared, and disappeared in four weeks. On June 3, 1944, he was wounded in the right thigh by shrapnel; this time, thinking it would be of no avail, he did not warn the medical officer that he was sensitive to sulphonamides. He had the wound dressed with sulphanilamide powder, and was given 2.5 g. of sulphanilamide. The next day he was sent to hospital with a moderately severe eruption. On admission the face, neck, upper part of the che[illegible] and the hands and arms were covered with a weeping crusted rash, with considerable swelling. The lower lip was raw and cracked. His skin healed well on 1% hydrarg. ammon. in Lassar's paste applied as a mask and as spreads, and he was discharged from hospital on June 23, tolerant to light. A label was affixed to his pay-book warning that he was sulphonamide-sensitive. He has kept well since.

Treatment of Type Ic

1. *Local.*—It was soon found that many drugs did not suit these cases, while others seemed to act almost as specifics. Saline soaks, ichthyol, but above all the flavine series, were unsuitable. In many instances the application of acriflavine had caused a marked exacerbation, and in five cases the use of this drug had produced a typical sulphonamide contact or light dermatitis in patients who had had this some months before, but who had not had any sulphonamide applied since that time. In this connexion the article by Russell and Beck (1944), pointing out the dangers of sulphonamide–proflavine mixtures in experimental wounds in rabbits, seems to show that each drug enhances the toxic reaction of the oth[illegible] It was found that in the crusted oedematous phase the most suitable dressing was lead and calamine or lead and zinc lotion, applied as wet dressings at least night and morning. Weak eusol or eau d'Alibour was also helpful. When the skin became less moist, with little oozing and crusting, a mask of 1% hydrarg. ammon. in Lassar's paste proved to be the most acceptable dressing: 2% hydrarg. ammon. often seemed to be too powerful, while the skin did not tolerate greasy applications such as ung. hydrarg. ammon dil. very well. This 1% hydrarg. ammon. paste healed the skin in two or three weeks, except in the severe cases, and it was then necessary to test the patient's tolerance to sunlight. The face, hands, and arms were therefore gradually exposed to light—on the first day for 5 minutes, the second day for 7 minutes, the third day for 10 minutes, and so on until the patient could bare his whole body for at least four hours to a strong sun. At first the skin was protected by an anti-light cream—quinoline derivatives and phenol salicylate were not available, and quinine sulphate creams proved of little use. The best cream was 5% tannic acid in a tragacanth or a lanette wax cream, which was applied liberally before exposure to the sun. Quercitannic acid, extracted from the cork oak in North Africa, was tried, but proved inferior to ordinary tannic acid. In the healing stage these sulphonamide–light eruptions closely resembled an impetiginized seborrhoeic dermatitis, and the drugs used in this condition were often employed—e.g., gentian violet 1%, silver nitrate 2%, etc. Penicillin cream also proved useful.

2. *General.*—(i) *Vitamin B complex* seemed to be indicated, as the photosensitivity brought to mind a nicotinic acid deficiency, and the crusted lesions of the mouth, the naso-labial folds, and the ears reminded one of a lack of riboflavin. Therefore yeast (in the form of D.C.L. tablets and dried yeast), multivite tablets, and stout were given in maximal dosage. The response was disappointing, though the impression was that yeast tablets seemed to have most beneficial effect. With the dose given the patients felt the "nicotinic acid flush," but the light sensitivity persisted as much as in those cases which were not given extra vitamins.

(ii) *Quinine sulphate and hydrochloride* were given to 20 cases—the doses being 5 gr. thrice daily—as they have been used with some beneficial effect in other dermatoses associated with sensitivity to sunlight—e.g., lupus erythematosus and erythema multiforme. In some cases the skin could tolerate full exposure to light after three or four days, but the photosensitivity returned after stopping the drug.

(iii) *Peptone* (5%, given subcutaneously thrice a week) was used in several severe cases, as its complex components seem to contain a substance or substances antagonistic to the sulphonamides (Heathcote, 1944). It had no effect whatsoever.

(iv) *Vaccines* were employed in many cases, as the predominant growth in every case was *Staph. haemolyticus*; they were helpful in patients with pustules and furuncles, but had no other effect.

(v) *Penicillin*, given intramuscularly, proved to be the most useful drug of all. It was used in a dosage ranging from 500,000 to 1,250,000 units, depending on the severity of the case. So far 23 cases have been treated. The sepsis usually disappeared within five days, leaving a tender healing skin. It had, of course, no effect on the light sensitivity.

(vi) *Sulphonamides.*—It was relatively easy to desensitize patients to the sulphonamides by starting with a tiny dose and increasing it daily. This, however, had no influence on the photosensitization; it was therefore of little practical value, and was discontinued.

(*d*) *Telangiectatic Type.*—This was seen in 4 cases, and was always the end-result of repeated attacks of a mild sulphonamide-light dermatitis. Two of the patients had been affected for over two years, the others for about four months. All had a typical appearance, somewhat reminiscent of a mild radiodermatitis—i.e., mottled pigmentation, fine telangiectasia, and early atrophy of the skin—associated with scattered islands of impetigo. One patient had some pre-carcinomatous keratoses. In all cases the condition was localized to the face, the "V" of the neck, and the back of the hands.

Illustrative Case.—Pte. E., aged 24; admitted to hospital on Oct. 21, 1944. Except for mild dandruff his skin had always been healthy. On June 28, 1944, he was wounded through the leg, which was dressed with sulphanilamide powder and then acriflavine. Three days after wounding a spotty rash appeared on the face and arms, which soon became crusted. He noticed that his lips were cracked and swollen. The erythema subsided but the crusting persisted. Various applications were used, and penicillin powder caused an acute exacerbation. On admission he showed pigmentation and telangiectasia of the brow, cheeks, neck, and lips, and odd patches of impetigo on the cheeks and brow. The latter cleared slowly but steadily with 1% gentian violet used alternately with 1% hydrarg. ammon. paste. Because of the atrophic changes he was invalided home.

II. Contact-type Dermatitis

This type was observed in 51 cases. It appears to have been first noted by York (1942), who described the treatment of 96 cases of staphylococcal infection of the skin: one boy with impetigo of the scalp developed a reaction—i.e., "punched-out ulcers appeared at the edge of the lesions," and healed readily on ammoniated mercury ointment.

According to the excellent papers on sulphonamide eruptions by Tate and Klorfajn (1944a, 1944b), this form of sulphonamide sensitivity seemed to be far commoner in the Middle East than the photosensitization type, which was so prevalent in North Africa and Italy. The reaction occurred most often on the limbs, but was seen occasionally on the head and trunk. Once a few cases had been seen a "spot diagnosis" was easily made, and confirmed by taking the history, but 5 cases (already mentioned) were healed sulphonamide dermatitis reactivated by acriflavine. The original lesion—usually a wound or a graze—had practically healed as a rule, and was surrounded either by bullae or, when they had ruptured, by small superficial ulcers, about 1 cm. in diameter, stippling a raw denuded surface. These ulcers were filled with a thin pus, which on culture gave a pure growth of *Staph. haemolyticus*, except for two cases which produced a growth of *Ps. pyocyanea*, with sparse colonies of *Staph. haemolyticus*: the latter cases had the clinical appearance of pemphigus foliaceus, with the typical large flaccid bullae and musty odour.

The ordinary sulphonamide contact dermatitis yielded rapidly o treatment: either wet dressings of lead and zinc lotion or veak eusol healed the ulcers quickly, and a dressing of Lassar's aste or zinc ointment protected the skin during the final ealing phase.

Illustrative Case.—Lieut. F., aged 31; admitted to hospital on arch 10, 1944. Six weeks before admission he grazed his left bow while playing football; the injury "went septic," and lphanilamide powder was applied on three occasions. A marked read of the infection ensued, so that the whole arm was affected. examination it was seen that the original graze had healed comtely. The whole forearm, from the deltoid to the wrist, was ered with septic blisters and small septic ulcers, with considerable ns of denuded skin. Wet dressings of lead and zinc lotion were lied, and on March 22 the arm had healed, leaving many healed hematous areas. He was seen again two months later, and his had remained well.

III. Infectious Eczematoid Dermatitis Type

This always began as a typical sulphonamide contact dermatitis, but the staphylococcal infection spread as impetiginous or ecthymatous lesions over the limbs, ears, and beard region. Thirty-one cases of this type were admitted; some of these had become markedly eczematized, and thus resistant to treatment. When seen in the early stages, however, the prognosis was excellent, and a speedy recovery was made. This type, like the contact one, is described by Tate and Klorfajn (1944a, 1944b).

Illustrative Case.—B.S.M. G., aged 25; admitted to hospital on March 23, 1944. On Feb. 19 a superficial gunshot wound of the left lower leg was treated with S.V.G. After several applications the wound had almost healed, but the surrounding skin became [illegible] and weeping, with septic bullae and superficial ulceration. The dermatitis spread until the whole leg was involved, and sores and blisters appeared on the arms, ears, chin, and neck. There was no photosensitivity. Both the leg and the secondary lesions healed quickly on penicillin cream (250 units in a lanette wax and adeps lanae cream).

IV. Disseminated Neurodermatitis Type

Only 4 cases of this type were seen; they were precisely similar except that one began after treatment of a wound in the thigh, two from patches of infective dermatitis, and one after sulphanilamide ointment had been applied to a patch of circumscribed neurodermatitis (lichen simplex chronicus) over the sacral region. The application of the sulphanilamide caused a sudden dissemination of erythemato-papular lesions with some lichenification on the neck, on the flexor surfaces of the forearms, especially in the antecubital fossae, and on the front of the thighs. None of these cases had any previous history, or family history, of skin disease.

Illustrative Case.—A.B. H., aged 32; admitted to hospital on May 30, 1944. About six months previously he felt an irritation just above the natal cleft, which caused him to scratch the part violently. Gradually the skin of that area became thick and leathery and intensely pruritic. He was seen by his doctor, who prescribed a 5% sulphanilamide ointment. After a few applications the rash spread "all over the body." The appearance on examination was typical of "eczéma neuropathique"; there was an erythemato-papular rash scattered over large areas of the body, with some lichenification and pigmentation. On the sacral area was a large thickened plaque of lichen simplex chronicus (Vidal). The patient, though a sailor with an almost heroic record, was a nervous introspective individual, intensely worried about home troubles. The resolution of these played an important part in the clearing of his skin condition, and he was returned to duty on June 20, with practically no itching but some residual lichenification, after treatment with crude gas tar.

V. Vesicular Type

Four cases of the vesicular type of rash were admitted, two being due to oral administration and two to local application of sulphonamides. The prognosis of these was excellent, as the vesicles rapidly disappeared, and the men could be returned to their units in a short space of time. Three were sent to hospital as cases of suspected smallpox: when the vesiculation was localized mainly to the exposed areas the appearance and distribution certainly suggested this diagnosis.

Case 1.—Lieut. I., aged 24. This officer was admitted to hospital on May 28, 1944, for treatment of an attack of bacillary dysentery, for which he was given sulphaguanidine tablets. When he had taken them for two days a vesicular rash appeared all over his body, and vanished in three or four days. A week later the tablets were again administered, and again a precisely similar rash appeared.

Case 2.—Dvr. J., aged 23, Sinhalese; admitted to hospital on May 8, 1944. For 2½ months this patient had had a dermatitis of the back of the left hand after an abrasion. On May 4 this became septic; acriflavine dressings were applied and sulphapyridine tablets (14 g.) given by mouth. On the 5th he developed malaise, giddiness, and a generalized rash, with intense pruritus. His body was covered by a vesicular rash, not unlike variola; the back of the left hand was raw and ulcerated, with marked oedema. In a week the generalized eruption had gone, but the original dermatitis of the hand did not heal completely till June 4. Though no sulphonamide had been applied to the patch of dermatitis the acriflavine had produced a typical sulphonamide contact dermatitis.

VI. Generalized Bullous (Pemphigoid)

Only one case of this type was seen, and only one could be found [illegible]cribed in the literature available—that in the [illegible] by [illegible] (1943).

Illustrative Case.—Lieut. K., aged 34; Polish officer; admitted to hospital under the care of Major H. C. Johnston, R.A.M.C., venereologist. This patient had contracted gonorrhoea, which his medical officer began to treat with sulphathiazole; after two days a slight rash appeared on the trunk, and the drug was stopped. However, the patient was determined to have sulphonamide treatment, and managed to secure some sulphathiazole in an illicit manner. He took two tablets, and next day was admitted to hospital with a generalized bullous eruption. He was extremely toxic and appeared to be desperately ill. His condition was very much like a true pemphigus, as the rash was entirely bullous, and Nikolsky's sign was positive; lesions were present on the tongue and the buccal mucous membrane. In order to treat his gonorrhoea, as well as any sepsis present, he was given penicillin intramuscularly: after 100,000 units the bullae disappeared, the mouth healed, and the skin was well within 7 days. His general health, however, remained poor, and even after some weeks at a convalescent depot he complained of weakness and lack of energy.

VII. Fixed Type of Drug Eruption

In this series—from Feb., 1943, to June, 1944—only one case of this type was seen, but since that time two other patients have reported with it. The eruption is essentially similar to the fixed erythema due to other drugs, such as phenolphthalein, the barbiturates, and arsenic. Since 1939, when Loveman and Simon described "sulphonamide fixed drug" eruption, several cases have been reported in the literature—by Director (1943), Dostrovski and Sagher (1944), and Freeman (1944), among others.

Illustrative Case.—Lieut.-Col. L. had for some years been troubled with a recurrent antral sinusitis, and obtained speedy relief by taking small doses of sulphanilamide, sulphathiazole, or sulphadiazine. As a rule the drug was used orally, but more recently he had been taking sulphathiazole powder as a snuff. Some months before, three scaly pigmented patches had gradually appeared on the face and chest, somewhat like a discoid lupus erythematosus. Each time sulphonamides were taken the patches became erythematous, swollen, and intensely pruritic. Macroscopic examination showed three circular, deeply pigmented lichenified plaques on the chin, forehead, and chest. The coloration was dark brown, there being no lilac tint and no follicular plugging. A histological section revealed a picture of chronic inflammation—hyperkeratosis, some acanthosis, increase of blood supply, and an intense round-cell infiltration.

VIII. Purpuric

In a severe case of sulphonamide dermatitis it is a common occurrence to observe purpuric lesions, particularly on the legs, but it is definitely unusual for the rash to be entirely purpuric in character. Shaffer mentions that purpura may be met with in sulphonamide eruptions, and I have now seen 8 cases with only a purpuric rash, 3 of these in the present series. Of the 8, one was due to administration of sulphanilamide tablets and the others to the local application of the powder. The rash in each case soon faded, leaving brown pigmentation.

Illustrative Case.—Capt. M., aged 31, was admitted to hospital with an ulcer on the front of the leg; this had appeared suddenly for no apparent reason 10 days previously. The sore was treated by the daily application of sulphanilamide powder. On examination a typical diphtheritic ulcer was seen; surrounding this was a plaque of purpuric skin, exactly square in shape—i.e., precisely the size of the white lint dressing which had been impregnated with the powder.

IX. Morbilliform

This rash is one of the commonest due to the sulphonamides, and usually occurs after oral administration. Though only 8 cases are included in this series, many others occurred in the hospitals in Africa and Italy. The eruption being well recognized by physicians and surgeons, the drug was withdrawn and the rash soon faded, so that the dermatologist did not often have the opportunity of seeing the reaction in full efflorescence. The rash is most pronounced on the trunk as a rule, but may affect all the skin and cause a vesico-bullous eruption of the hands and feet, with intense pruritus. It is precisely similar to the drug eruption due to the barbiturates—e.g., medinal—and, of course, no photosensitization develops.

Illustrative Case.—Sgt. N., aged 28, was admitted to hospital on Feb. 29, 1944, with an extensive infectious eczematoid dermatitis, which had begun after the secondary infection of an abrasion. The ar[illegible] legs, and buttocks were affected by crusted septic patches of [illegible]tis. After initial improvement he had a relapse on March 8; [illegible] the 9th was given sulphanilamide tablets [illegible] g. he developed a morbilliform rash on the trunk, limbs, and face, with a vesico-bullous eruption of the palms and soles. By the 13th the rash had disappeared except for some pigmentation, and a "gumboil" had suddenly made its presence felt in the lower jaw. Radiography showed evidence of a large apical abscess; the tooth was extracted, and his dermatitis healed rapidly and steadily. His skin two months later was still perfectly well.

X. Scarlatiniform

Only 2 cases of this type were seen, perhaps chiefly because it is an evanescent rash and usually disappears within 24 or 48 hours. The whole body may be affected, but as a rule the trunk is the main site of the eruption. Like the morbilliform, this type does not seem to be associated with photosensitivity, and patients who have had this rash tend to have the same manifestation if sulphonamides are given again.

Illustrative Case.—Spr. O., aged 22; admitted to hospital on March 16, 1944. Thirteen weeks previously he developed a boil on the right ankle. This was treated with S.V.G. for about a week, after which a weeping eruption appeared on the surrounding skin (i.e., sulphonamide contact dermatitis). On March 11, as the leg seemed to be "septic," he was given 5 tablets (2.5 g.) of sulphanilamide. Five hours later a rash appeared over the whole body, and the dermatitis of the ankle became much more pronounced. On admission he was covered with a scarlatiniform rash, and had a temperature of 102° F. The dermatitis of the right ankle was a typical sulphonamide contact dermatitis. By March 24 the leg had almost healed (the scarlatiniform eruption had disappeared by the 19th), but he had developed numerous boils. He was evacuated on the 25th, as beds were urgently required for fresh admissions.

XI. Urticarial

Two cases of acute urticaria after administration of sulphonamides were seen—one after sulphathiazole and one after sulphathiazole and sulphaguanidine. In both the rash faded in two or three days.

Illustrative Case.—Tpr. P., aged 24, was admitted to hospital on June 8, 1944, because of diarrhoea. His story was interesting. About the end of May he sustained multiple but superficial wounds, and was admitted to a casualty clearing station, where he was given sulphathiazole tablets by mouth. The next day a generalized rash appeared, apparently urticarial in nature; it vanished in two or three days. On June 8 he had a sudden attack of diarrhoea, and was transferred to the medical division of the hospital. On the 12th he was given sulphaguanidine, and next day was covered with urticaria, which disappeared in 12 hours. On July 2 he had further diarrhoea; 12 tablets of sulphaguanidine were administered, and in 3 hours the urticaria again erupted, disappearing within 12 hours.

XII. Lupus Erythematosus Type

The 5 cases seen were all patients who had been treated with oral sulphonamides for chest conditions—wounds with infected haemothorax or bronchopneumonia. The rash appeared after at least 30 g. had been given. It was exactly similar to an acute lupus erythematosus, and involved the cheeks, nose, brow, and sometimes the "V" of the neck, with the typical colour, scaling, and follicular plugging, but disappeared except for some desquamation in 7 to 10 days after stopping the drug and applying ichthyol–calamine lotion.

Illustrative Case.—Pte. Q., aged 21, was admitted to hospital in May, 1944, with a severe penetrating chest wound, which had cause an infected haemothorax. He was operated on by No. 2 Surgic Chest Team, and given sulphathiazole by mouth. His general con tion improved steadily, but after 28 g. of the drug he develo erythematous lesions on the cheeks and brow, the appearance distribution of which were most suggestive of lupus erythematos

XIII. Erythema Multiforme Type

In 5 of the 6 cases seen the eruption was a typical ery multiforme, and each patient gave a history of having throat, which was treated with sulphonamides orally possible that the rash might have appeared whether t had been used or not, as the lesions and course of t were indistinguishable from true erythema multifo case, however, was somewhat different. This patient sergeant who had had severe abdominal wounds which tated major surgery. The damage was skilfully repaire given sulphanilamide, but his temperature remaine no apparent reason. As either a streptococcal or coccal septicaemia was feared despite sterile blo the sulphanilamide was stopped and sulphathiazole

The temperature still remained high, and an erythematous rash appeared on his neck. This was a patch of erythema multiforme. The drug was withdrawn, and in two days his temperature fell, the rash disappeared, and he made an uninterrupted recovery.

XIV. Erythema Nodosum Type

Some of the 5 in this group were quite ordinary cases of this disease, while two showed circinate erythematous plaques which were more superficial than the typical erythema nodosum and were not extremely tender. Similar lesions have been described by Miescher (1943) as occurring on the limbs and face after oral sulphathiazole.

Illustrative Case.—Guardsman R., aged 26, was admitted to hospital with a cellulitis of the leg following an abrasion, and was given sulphathiazole by mouth. Within 24 hours the front parts of the legs were studded with numerous tender indurated erythematous plaques, which gradually disappeared, leaving brown pigmentation. A general examination, including radiography of the chest, revealed no physical changes.

XV. Pustular or Acneform Type

Though Shaffer *et al.* (1943) have described a case of pustular exacerbation of an acne vulgaris after oral sulphathiazole in a man whose skin had been sensitized by the previous use of a sulphathiazole lotion, the 4 cases in this series were all seen as an end-result of sulphonamide medication. The patients had either had a sulphonamide–light eruption, which had disappeared, leaving pustular lesions on the face, or had had a sulphonamide contact dermatitis, which had healed, leaving a persistent folliculitis that had proved difficult to clear.

Illustrative Case.—Spr. S., aged 32, was admitted to hospital in May, 1944, with a sulphonamide contact dermatitis of the left leg. Three weeks before admission he had grazed the calf of his leg on barbed wire, and sulphanilamide powder had been applied daily as a dressing. After 7 days the graze had practically healed, but a weeping dermatitis about 4 in. square developed. This healed rapidly on wet dressings of lead and calamine lotion, but follicular pustular lesions which were present persisted for 7 weeks after the original dermatitis had healed.

XVI. Exfoliative Dermatitis

Many patients, of course, had a complete exfoliation as the drug rash faded, especially in the morbilliform and scarlatiniform types, but in 5 a severe exfoliative dermatitis was produced, chiefly by the combination of local and oral sulphonamides. Some of these took many weeks to get better, and three patients had to be invalided home.

Illustrative Case.—Pte. T., aged 23, was admitted to hospital on March 10, 1943. For three months he had had a "running ear," treated in various ways, including insufflation with sulphanilamide powder. By February the pinna was involved and the eyebrows became crusted. He was admitted to a forward hospital, where the ears were treated daily with sulphanilamide powder and he was given sulphanilamide tablets four-hourly. A severe generalized dermatitis developed, and he was evacuated towards the base. In Dec., 1942, insufflations of sulphanilamide powder had cured his "running ear" in 4 or 5 days. About the end of Jan., 1943, he developed impetigo of both ears; this gradually spread to the face, and he was admitted to hospital in a forward area, where the infection was treated with sulphanilamide powder. The crusting spread rapidly after this (i.e., sulphonamide contact dermatitis), and he was then given sulphanilamide tablets four-hourly (number unknown). Within 24 hours of swallowing the first tablets his face swelled, with marked oedema of the eyelids, conjunctivitis, and photophobia. The face and neck were crusted and oozing, a mass of blisters appeared on the hands, and a rash erupted all over the body. When first seen, on March 10, 1943, after he had been evacuated towards the base, he had a generalized exfoliative dermatitis, all the skin of the body being raw and crusted and the lips, tongue, and buccal mucous membrane swollen and ulcerated. There were purpuric lesions on the legs, and the scrotum was oedematous and raw. The temperature was 102° F.; pulse rate, 112. Urine: albumin +; sugar —; bilirubin +++; porphyrins —. He was extremely ill and toxic.

Discussion

In the Central Mediterranean theatre skin sensitization due to sulphonamides ranks as an important problem: every patient with a chronic seborrhoeic dermatitis of a particularly severe impetigo has to be questioned closely regarding sudden exacerbation or photosensitization after the application of a powder or ointment or after the ingestion of tablets. In July, 1943, the Director of Medical Services, A.F.H.Q., B.N.A.F., issued an instruction that sulphonamides should not be used in skin conditions or minor injuries except under the direct supervision of a dermatological specialist. This order was repeated on several occasions, while at a later date surgeons were warned about the dangers of sulphonamide powders for ear disease, and the necessity for avoiding prolonged use of these powders in wounds and burns.

Fortunately, most of the rashes due to internal administration of the drugs soon disappeared, unless the skin had been previously sensitized by local application. Internal medication can precipitate any of the various kinds of eruption, even the contact type, once the skin has been sensitized. Thus the erythematous and morbilliform and the fixed types do not matter greatly. On the other hand, the bullous (pemphigoid) eruption may be a grave illness, and the patient may even die (Kennedy, personal communication), while Shaffer *et al.* report two cases which each took four months to recover. It resembles "butchers' pemphigus," and the patient appears to be extremely ill. The rapid response to a comparatively small dose of penicillin (100,000 units—it was a precious drug at that time) of the single case reported here is definitely encouraging.

The two forms which caused most trouble to the dermatologist were the contact and light eruptions. The great proportion of cases of sulphonamide contact dermatitis healed rapidly with appropriate treatment, but only too often the patients were admitted to hospital with a chronic eczematous process that tended to relapse after apparent cure.

More distressing still were some of the cases which had become photosensitive. The mild erythemato-papular type caused little disability, and the light sensitivity soon disappeared. The severe cases, admitted with oedema and crusting of the exposed areas, cheilitis, conjunctivitis, and a high temperature, took weeks or months to recover, and the tendency to relapse was so evident that the greater number were invalided home even though their skins seemed healthy. For example, out of a series of 65 cases, mild and severe, seen in North Africa in 1943, over 20 were sent home from that country; of the remainder, 11 were seen again in Italy in 1944 and invalided home with (1) a recurrence of their light sensitivity, sometimes but not always due to a further use of sulphonamides or acriflavine—5 cases; or (2) chronic eczema—3 cases; or (3) resistant staphylococcal infections (e.g., recurrent impetigo or seborrhoeic dermatitis, chronic furunculosis or folliculitis)—3 cases. These men seemed to have a skin unable to resist staphylococcal infections.

Four patients were seen with the telangiectatic type of sulphonamide–light eruption; their future may also be viewed with some concern, the atrophy, pigmentation, and telangiectasia having the appearance of a radiodermatitis or mild xerodermia pigmentosa rather than a chronic solar dermatitis, though only one had pre-carcinomatous lesions.

It is difficult to assess how long a man will remain sensitive to light. In the mild erythemato-papular cases the patient may well be able to tolerate light within 48 hours, while in the worse types men have been seen still photosensitive after 2½ years. The amount of the drug does not seem to play an important part, as some of the worst cases had had only two or three applications of sulphanilamide powder, and some of those who recovered rapidly had been dosed with large quantities of assorted sulphonamides.

The chronic cases do not resemble other light dermatoses, such as Hutchinson's summer prurigo, but are to all intents and purposes cases of chronic seborrhoeic dermatitis with a profuse dandruff, crusting of the eyebrows, chin, and ears, and often flexural seborrhoea. A careful history will elicit the use of sulphonamides and exacerbation on exposure to light localized to the face, neck, hands, arms, and knees.

It was significant that sulphanilamide in powder form was most liable to cause sensitization, but sulphanilamide in vaseline is almost as bad. This drug, probably because it was most commonly employed, was responsible for over 90% of all reactions. Only a few cases were caused by sulphadiazine and sulphaguanidine. Most patients appeared to be sensitized to all the sulphonamide drugs, but occasionally there was a selective sensitization, well described by Park in a recent paper.

The treatment of skin conditions such as impetigo, seborrhoeic dermatitis, and secondarily infected tinea led to the greatest number of reactions:

Dermatoses	62.66%
Otitis externa	4.00%
Wounds	13.00%
Grazes and minor injuries	14.33%
Burns	4.00%
Other diseases (e.g., tonsillitis, appendicitis)	2.00%

It seems impossible to determine what percentage of people treated by sulphonamides locally develop sensitization, but it is interesting to note the experience of other dermatologists in treating skin infections with these drugs. For instance, Pillsbury *et al.* (1941) treated 190 varied cases with no evidence of absorption and no local or general reaction; Kalz and Prinz (1942) treated 130 patients with no systemic effects and no mention of dermatitis; York (1942) had one case of contact dermatitis in 96 cases; the Robinsons (1941), in a series of 48 cases of impetigo, had two cases of contact dermatitis; Glicklich (1942) saw no toxic effects in 42 cases; Ingels (1943) had 10 cases of sensitivity in 300 cases; with microcrystalline sulphathiazole Bigger and Hodgson (1944) had one case of sensitivity in 50 cases treated; of 196 patients treated by Costello *et al.* (1942) 21 had skin reactions—i.e., of 1,052 cases treated 3.5% became sulphonamide-sensitive. Before I abandoned the local application of these drugs, out of 400 cases treated with 5% sulphathiazole paste or cream I observed 4 which developed photosensitization, either mild or severe.

There seems to be little doubt that sulphonamides can be applied to the skin, as Pillsbury (1944) says, with little risk of causing sensitization if the process is not an eczematous one and the drug is used for not longer than 5 days in the form of a thick paste or water-miscible cream; but as diseases such as impetigo can be treated satisfactorily by other methods, it appears that sulphonamides should no longer be used as a topical application.

In 1943 I performed various tests on men with the light eruption. Patch tests gave erratic results, as they were invariably positive on areas previously affected by the rash—i.e., the parts exposed to light—and usually negative on other parts of the skin. Scratch and intradermal tests were rarely used, as they tended to cause (as often happens with these tests) an exacerbation of the original condition.

Complexion had, it appeared, little or no significance in this series of cases—in fact, the rufous type seemed less prone to severe reactions, while the worst cases were seen in men with dark hair and skin. Photosensitization was seen in Indians, Gurkhas, Sinhalese, and men of negro stock.

The incidence of sulphonamide reactions in the U.S. Forces seemed to be much lower than in United Kingdom, Dominion, or Empire troops: light eruptions were rarely seen, but occasionally the other types occurred. Two busy American dermatologists practising during the twelve months of 1944 in the same theatre of war saw in their own group of patients only 4 cases each that were definitely due to the sulphonamide series. Several reasons for this extraordinary difference may be suggested, but the most important are that the commonest way of using sulphonamides locally in the U.S. Medical Corps was in the form of 5% sulphadiazine in a water-miscible cream, and that acriflavine was seldom employed. Not unnaturally, American colleagues were sceptical of the high incidence in British troops until they were absolutely convinced by the numbers of cases shown them.

Summary

From Feb., 1943, to Dec., 1944, over 650 cases of cutaneous sensitivity to sulphonamides have been seen in North Africa and Italy; of these, 500 are reported and classified into 16 various types.

These reactions were due to the treatment of many different conditions, from major wounds and burns to slight grazes, impetigo, and chancroid.

Only 3 of the types described are liable to cause a grave or prolonged illness—i.e., the pemphigoid, the sulphonamide-light eruption, and the sulphonamide contact dermatitis.

Sulphonamide-light dermatitis accounted for 72.2%, and contact dermatitis and its complications for 17.2%—i.e., 90% of the total.

Most cases of reaction were due to the use of sulphanilamide in powder form; the safest drugs appeared to be sulphadiazine and sulphaguanidine.

Acriflavine can reactivate a sulphonamide-light or contact dermatitis just as may cocaine.

No race is exempt from this sensitization—skin colour and texture make little or no difference.

Sulphonamide reactions are uncommon in U.S. troops compared with British.

The local application of sulphonamides is contraindicated in skin diseases, though there is little risk if the drugs are used with certain precautions.

Intramuscular penicillin appears to be the treatment of choice in two types—the pemphigoid and the severe light dermatitis.

PREVENTION OF SEA-SICKNESS IN ASSAULT CRAFT

A REPORT OF EXPERIMENTS UNDER TROPICAL CONDITIONS

BY

IAN G. W. HILL, T.D., M.B., F.R.C.P.Ed.
Brigadier, A.M.S.; Consultant Physician to an Army Group

AND

A. I. GUEST, M.B., B.Chir., M.R.C.P.
Major, R.A.M.C.; Medical Specialist

Assault landings in combined operations entail the transport of large numbers of men in small craft over seas which may be rough. Previous experience in operations (such as the invasion of Sicily) and in training has shown how disabling sea-sickness can be to troops taking part in such landings. In many countries a number of remedies have been tested in the search for a means of preventing or mitigating sea-sickness without impairment of the fighting efficiency of troops when disembarked on the beaches.

From the reports of previous workers it appears that the most efficient remedy is hyoscine (Holling, McArdle, and Trotter, 1944; Holling and Trotter, 1944); other members of the atropine series are less effective. Amphetamine (benzedrine) had been claimed by Hill (quoted by Jowett, 1943) to reduce the sickness rate dramatically, but was found by Jowett and Thomson (1943) to be ineffective. A combination of hyoscine with amphetamine has been claimed (Jowett, 1943; Jowett and Thomson, 1943) to be highly effective. Chlorbutol has been found of little value (Holling and Trotter, 1944).

The possibility of side-effects being produced by hyoscine has been the subject of much research. The reduction in salivation, with consequent dryness of the mouth, is merely inconvenient. But the effects on the eye might, if severe, interfere with efficient shooting, observation, etc.; the sedative action might produce drowsiness; and, most important of all in tropical climates, the reduction in sweating might prove dangerous from interference with heat-loss. Both in Britain and in India tests with this drug have been carried out to determine whether these effects are pronounced enough to detract from its beneficial action in sea-sickness. Its effects on the stamina of troops and on their ability to perform complicated mechanical operations (stripping and reassembly of Bren guns, etc.) have been studied, and the performances of treated and untreated groups of men on the rifle range compared. Ophthalmological investigation of possible effects on accommodation and fine eye movements has been carried out (Wilson, quoted by Holling and Trotter, 1944). All reports agree that no undesirable effects are produced by the drug in the doses advocated for the relief of sea-sickness.

Studies have been made on two individuals working in a hot chamber reproducing tropical conditions, but no large-scale tests have so far been reported.

The experiments described in the present paper were carried out to determine the influence of this and other drugs on the incidence of sea-sickness among troops of various nationalities, and on the possible production of undesirable side-effects, under tropical conditions.

Material.—A group of over 5,000 men in training was used for the tests. The racial composition of the men was as follows: British troops, 1,667; Indian troops, 3,673; mixed (composition not recorded), 400. The various sects and races of Indian troops observed were: Punjabi Mussulmans, 637; Dogras, 206; Pathans, 316; Gurkhas, 1,586; mixed (Ajmirs, Brahmins, Ahirs, Moslems, Mundas, and Hoes), 928.

Meteorological Conditions.—The experiments were carried out on the west coast of India in latitude 19° N. during the month of May, approximately one month before the monsoon. Climatic conditions were average for place and season (see Table VII). Briefly, temperature and humidity were such as to favour the development of heat-stroke or heat-exhaustion in individuals performing strenuous exercise; sea conditions were never rough enough to produce more than 15 to 25% of sickness among unseasoned troops sailing in small craft.

Methods

During the investigation the troops were engaged on a full scheme of training, and experiments had to be designed so as not to interfere with this programme. In general it was impracticable to send parties of men to sea for the sole purpose of testing sea-sickness. Each experimental observation had to be fitted into the scheme of an assault exercise, planned and unalterable. This was usually possible, while still observing the essential conditions of the experiment—viz.: (1) the simultaneous observation under identical conditions of large numbers of men sailing at the same time in similar craft from the same starting-point to the same destination; and (2) their division into two or more groups of comparable size, one such group receiving inactive tablets (controls), while the other group or groups received tablets of the substance under test. Tablets were distributed one hour before embarkation to the selected groups of men, either by R.A.M.C. orderlies attached for duty in these experiments or by company commanders under the guidance of the unit medical officer. Particular care was taken to ensure that every man swallowed his prescribed pill. In all experiments the men in test and control groups alike were given paper vomit-bags, a supply of sweets, biscuits, and chewing-gum, and were instructed in the simple measures found by previous workers to reduce sickness among men crowded in small craft (i.e., keeping the deck clean by using bags for vomiting; eating a biscuit or a few sweets if slight nausea occurred). The chewing-gum was intended to reduce the unpleasant dryness of the mouth with hyoscine, but was given to all, irrespective of what drug they received.

The principles on which an experiment was planned may best be understood by consideration of an example.

Experiment V.—2/Blankshires; May 8/9, 1944

Three assault companies of a battalion, sailing in nine "Landing Craft Assault" (L.C.A.s) at 22.30 hours from the same point, were due to land on a beach at 02.00 hours and carry out an assault. Each L.C.A. carries 35 men, and the personnel allocated to each craft was given a serial number. Three serials or boat-loads were allotted to each company: Nos. 1–3, 4–6, and 7–9 respectively to the first, second, and third companies. Serial 10 was composed of Headquarters staff. Serials 11, 12, and 13 were made up of various auxiliary troops sailing in 3 L.C.A.s; serials 14, 15, and 16 carried the three platoons of the reserve company in 3 L.C.A.s. Serials 11–13 sailed at 22.30 hours and disembarked at 02.20 hours on the same beach as serials 1–9; serials 14–16 sailed at 23.40 hours and disembarked at 02.45 hours on the same assault beach. In addition several "Landing Craft Mechanized" (L.C.M.s) were employed carrying few men in addition to their vehicle loads, and three larger craft—one "Landing Craft Infantry (Large)" (L.C.I.(L.)), and two "Landing Craft Tank" (L.C.T.s). The former carried 185 men of various units, sailing at 17.00 hours the afternoon before the assault, and landing at 03.45 hours. The L.C.T.s carried respectively 66 and 81 men, sailing at 21.45 hours and 19.30 hours respectively from a different jetty, and landing their troops at 04.00 and 05.15 hours respectively.

In planning the experiment the first nine serials carrying the three assault companies were treated as a group. The remedies to be tested and the control tablets were distributed as follows:

Serial No.	Remedy	
1	Sod. bicarb.	each 1 platoon of 1st Coy.
2	Hyoscine	
3	Ergotamine	
4	Sod. bicarb.	each 1 platoon of 2nd Coy.
5	Hyoscine	
6	Ergotamine	
7	Sod. bicarb.	each 1 platoon of 3rd Coy.
8	Hyoscine	
9	Ergotamine	

The other six L.C.A.s (omitting HQ. in serial 10) were also treated as a group, and remedies distributed as follows:

Serial No.	Remedy	
11	Hyoscine	mixed troops
12	Hyoscine plus ergotamine	
13	Sod. bicarb.	
14	Hyoscine	each 1 platoon of reserve company
15	Hyoscine plus ergotamine	
16	Sod. bicarb.	

The men on the larger craft (serials 21, 22, and 23, sailing in the L.C.I.(L.) and L.C.T.s) were divided into roughly equal groups on each ship. To one party was given hyoscine, to the other sodium bicarbonate. It will be noted that in these craft controls and test groups were mingled, while in the smaller L.C.A.s carrying 30 to 35 men all individuals in one craft had the same pill—active or dummy, as the case might be. The small number of men carried in the L.C.M.s were omitted from the experiment.

Trained nursing orderlies, R.A.M.C., detailed for this duty, sailed in each craft as observers, one to each L.C.A., six in the L.C.I.(L.), and two to each L.C.T. They were provided with forms on which to record the names of all seen to vomit or noted to suffer from nausea. Details of actual times of sailing and disembarking, of entering and leaving rough waters, of lying "hove-to," and the code letter of the remedy administered to troops on board had to be entered in the spaces provided on the form. The orderlies followed the troops for half an hour after disembarkation to note any sign of illness or incapacity among the men. Arrangements had been made to deal with heat-stroke cases, should such occur.

It was considered that opinions regarding the military efficiency of the men would have most value if expressed by their own officers. Familiar with their men's usual behaviour, and with the particular situation as it developed on the beaches, they could be relied on to detect any abnormal reactions.

Figures from the analysis of the results of this experiment will be found in the Tables and the discussion below. It will be noted that in assessing the efficiency of a remedy due regard is paid to comparison with the control group sailing in identical craft over the same course at the same time.

Of 17 experiments, Nos. V, VI, and VII were of this type. Experiments I, II, and III were similar, except that in these the exercise was carried out by companies of infantry without ancillary troops; all serials sailed in L.C.A.s. Experiment VIII was an observation of a group selected out of over 5,000 men taking part in a large-scale exercise; it is discussed in detail below.

In several experiments (Nos. IX, X, XIV, XVI, and XVII) parties of men were sent to sea for a six-hour trip in "country-craft." These were 170-ton ocean-going dhows, all exactly similar. In each experiment a party of 150 men was divided into two groups of 75; each sailing in one dhow; to one group was given the remedy under test, to the other an inactive pill. So far as was possible the craft sailed together, under identical conditions, and remained at sea for the same time. R.A.M.C. observers sailed on each to record the incidence of sea-sickness. These trips were all by day; no exertion was demanded of the troops on disembarkation.

In another series of experiments parties of 120 to 200 men with R.A.M.C. observers sailed on an L.C.I.(L.) for a six-hour trip (Expts. XI, XII, and XIII). The men on board were divided into three groups without selection. To one group (controls) the inactive pills were given; to each of the other groups was given one of the remedies under test. No exertion was demanded of the troops on landing.

Remedies Tested.—Since hyoscine had already proved in other countries to be the drug of choice, and since data were required on its action in Indian troops and under tropical conditions, this remedy in a dose of 1/100 gr. was chosen for special study. In view of the preference expressed by other workers for a combination of hyoscine (1/100 gr.) with amphetamine (5 mg.) a number of experiments were made in order to compare the efficiency of this combination with that of hyoscine alone. Ergotamine (0.5 mg.) was also tested, alone and in combination with hyoscine (1/100 gr.), because of its known power to relieve the nausea, etc., of migraine and the possible benefit to sea-sick subjects of the "sympathicotonic" type. Chlorbutol in doses of 10 gr. was compared with hyoscine (1/100 gr.) under controlled conditions.

Heat-stroke Precautions.—The season and climate in which the experiments were carried out rendered heat casualties likely among large bodies of troops engaged in strenuous work. In view of the possible effect of hyoscine in suppression of sweating, preparations were made for the treatment of heat casualties on a large scale should they occur.

Results and Discussion

1. Action in Prevention of Sea-sickness

In the course of 17 experiments a total of 5,740 men were subjected to tests. Among these were 2,206 men to whom inert "placebo" tablets of chalk or sodium bicarbonate had been given, and who acted as controls for the groups receiving the active drugs. Owing to various causes a large number of results had to be discarded as useless for analysis.

Because of calm seas, the sickness rates in the control groups in eight experiments averaged only 2.3%. Such experiments are useless for estimating the potency of remedies, and were discarded. Again, on two occasions after men had taken their remedies as issued the sailing of the craft was cancelled for naval reasons. In a third group the men on a L.C.I.(L.) were at sea for 21 hours; they had been issued with their remedies 13 hours after embarking and 8 hours before landing. A number were ill before the remedies were given, and a number of others more than six hours later, when the period of expected action of the drugs was over. The effect of the remedies during their period of likely action could not therefore be accurately assessed, and the experiment was discarded.

The total number of observations discarded was 2,102; the observations remaining for analysis total 3,638.

A consolidated summary of all valid experiments is given in Table I. The average incidence of vomiting recorded in 1,385 control subjects was 12.4%; an additional 3.6% were nauseated. The total personnel affected in the control group was thus 16%. Rough comparisons only are permissible from this table in considering the figures for sickness incidence with various remedies, since the aggregate figures for many experiments are being compared rather than the figure for each remedy contrasted with its twin control group.

For comparison of the preventive effect of various remedies a "protective index" is advocated by Holling *et al.* (1944). This is obtained from the formula

$$\text{P.I.} = \frac{\%\ \text{Sick in control group} - \%\ \text{Sick in test group}}{\%\ \text{Sick in control group}} \times 100$$

This expression "shows the percentage of the sick in the control group who presumably would not have been affected if they had been in the test group" (quoted from the statistician's report on our experiments). This index for each experiment is given in the analytical tables. The indices in Table I show that ergotamine used alone fails to protect an appreciable percentage of susceptible individuals, while hyoscine alone or in combination with amphetamine protects over 70% of those liable to sea-sickness.

More exact analyses of these figures are given in Tables II to IV, in which figures for each remedy are compared with those from exactly comparable control groups. For example, in Table II (a) figures for hyoscine-treated individuals and controls, all sailing in L.C.A.s under exactly comparable conditions, are contrasted; and so for other series.

The individual hyoscine experiments of Table. II were analysed, evaluating the protective index in each experiment, to determine (*a*) the range of value, and (*b*) whether the index varies significantly with the sickness incidence in the control group. The results of this analysis are given in Table V.

Table V.—*Analysis of Protective Indices in Individual Experiments: Remedy, Hyoscine; Craft, L.C.A.s*

Expt. No.	Total Observed		Vomited		Total Affected		Protective Index	
	Controls	Test Group	Controls (%)	Test Group (%)	Controls (%)	Test Group (%)	Vomiting (%)	Total Affected (%)

VI	103	104	10·7	6·7	10·7	6·7	37·4	37·4
VIII (a)	104	105	17·3	3·8	28·8	3·8	78·0	86·8
VIII (b)	102	105	2·9	2·8	6·8	7·5	0·34	minus
XV	105	103	9·5	0	14·3	1·0	100·0	93·0

With two exceptions—Expts. VI and VIII (b)—the values of the protective index are all over 70%. The two strikingly low indices require further consideration.

Expt. VI.—In this experiment the remedies were administered to the troops as they boarded their craft, immediately before putting to sea. In other experiments of this series the remedies were given about one hour before sailing. There had not been sufficient time for absorption of the drug before the men were exposed to rough seas.

Expt. VIII (b).—In this case there is a discrepancy between the figures recorded by the R.A.M.C. observers and those reported by the men's company commander. The latter reported 7% of the test group sick, and 25% of the control group. The observers' figures have been retained to avoid any suspicion of manipulation of results. The protective index as calculated from the company commander's figures would indicate protection of the same order (72%) as in the other experiments in Table V.

Acclimatization.—Repeated exposure of the same individuals to the motion of the craft at sea was noted to produce some reduction in the incidence of sickness among the control (untreated) group in successive experiments. Possible fallacies in the experimental results due to this acclimatization were avoided through the method adopted of comparison of treated groups in all cases with a control group of similar individuals sailing under identical conditions.

Statistical Analysis of Results.—The results were reviewed by the Central Statistical Section, G.H.Q. (India). Values of χ^2 and of P calculated for each experiment are given in Table VI. The statistician's estimate of the reliability of each result is given in the final column of the table.

The results for hyoscine, with the exception of Expt. VI, are "reliable" or "highly reliable." The figures from Table II (a), derived from observations on 929 instances of hyoscine administration, have a probability of less than 1 in 100,000 that the observed effects were due to chance. The results for hyoscine plus amphetamine also are assessed as "highly reliable," with a probability of their being fortuitous of less than 1 in 10,000. The statistician considers, therefore, that the observed differ-

Table VI.—*Statistical Analysis of Tabulated Results*

(χ^2 = Measure of statistical reliability of the result. P = Probability that the result is independent of the use of the drug.)

No. of Table Analysed	Type of Craft	Drug Administered	Protective Index	Total Cover Index	χ^2	P	Reliability of Result	Remarks on Reliability
II (a)	L.C.A.s	Hyoscine	78·7%	96·2%	94·6	$<0{\cdot}00001$	Highly reliable	Large sample; 929 men
II (b)	L.C.M.s L.C.T.s L.C.I.(L)	,,	95·0%	99·5%	19·5	$<0{\cdot}0001$	Reliable	Good sample; 215 men

	L.C.A.s	Hyoscine and amphetamine	72·0%	93·0%	35·8	$<0{\cdot}0001$	,,	Good sample; 377 men
III (b)	L.C.A.s	Hyoscine	100·0%	100·0%	8·7	0·003	Not reliable	Sample too small for reliability
	L.C.A.s	Hyoscine and ergotamine	75·3%	96·2%	4·0	0·045	,,	Small sample; 52 men
IV (a)	L.C.A.s	Ergotamine	0	86·5%	0·92	0·337	* ,,	Good sample*; 186 men
IV (b)	Dhows	Chlorbutol	72·2%	92·1%	20·4	$<0{\cdot}0001$	Reliable	Good sample; 151 men
IV (c)	L.C.A.s	,,	32·9%	89·8%	1/1	0·294	*Not reliable	Good sample*; 98 men

* In these cases χ^2 is low although the samples are large enough to give a significant result. This suggests lack of efficiency of the drug used.

ences in protective indices for the two remedies are probably real. Further analysis by another method (standard deviations) confirmed this conclusion. This implies that the observed lower figures for protection by hyoscine plus amphetamine express an actual inferiority to hyoscine alone, under the conditions of the experiments.

The results for ergotamine, alone and combined with hyoscine, are assessed as "not reliable," since there are probabilities of from 337 in 1,000 to 45 in 1,000 that such results as were observed might be due to chance. In the footnote to Table VI it is pointed out that the unreliability of the results for ergotamine is not due to small samples. The low value for χ^2 is dependent on low observed differences between sickness rates in test and control groups. This statistically suggests that the drug (ergotamine) is not an effective remedy.

So, also, the results for chlorbutol in L.C.A.s are "not reliable," with a nearly 30% chance of error. The figures for chlorbutol derived from observations in dhows, however, are "reliable" and the chance that the results observed were unconnected with the remedy is less than 1 in 10,000. The wide disparity between the chlorbutol results in the two types of craft has not been explained. Further experiments would be required to define the efficacy of this drug.

Comparison of "Protective Index" and "Total Cover Index."—The protective index of Holling *et al.* has already been described. The "total cover index" is the percentage of men not affected in the test group, and includes those naturally immune plus those protected by the remedy given. From it the expectation of sickness with a given remedy is known. The values of both indices are given in Table VI.

Comparative Efficacy of Drugs.—Of the remedies tested in which the results are acceptable to the statisticians the degree of protection afforded by hyoscine is the highest, being throughout of the order of 80% as gauged by the protective index, and 96% as gauged by the total cover index. Hyoscine plus amphetamine gives somewhat lower figures, with a protective index of 72% and a total cover index of 93.6%. Chlorbutol in dhows shows protection of the same order (75% and 92% by the two indices).

2. Hyoscine and Heat-stroke

From Table VII it will be seen that during the investigation hyoscine was administered to a large number of men. The subjects were in part British troops (780) and in part Indian troops of many races and sects (1,951). Throughout the period of the experiments the climatic conditions were favourable for the development of heat-stroke and heat-exhaustion, as is shown by the meteorological data in the table. In the great majority of cases (2,213) the men who had had hyoscine underwent fairly strenuous exertion immediately after landing on assault beaches, comparable in degree to that demanded by actual battle conditions.

TABLE VII.—*Meteorological Conditions during Hyoscine Experiments*

Expt. No.	Total Men Engaged	No. of Men c̄ Hyoscine	Nature of Exercise	Time of Day	Meteor. Conditions				Observed Effects of Heat

* All among personnel *not* receiving hyoscine.

Throughout these experiments, in which over 2,700 men were given hyoscine, no case of heat-stroke occurred among those who had had the drug.

On one large-scale exercise (Expt. VIII) 424 men had hyoscine and carried out a very strenuous assault without incident. During this exercise one fatal case of heat-stroke occurred in a British soldier. This man was in the "control" company of a battalion that had had a pill of chalk at midnight on May 16–17. He disembarked with his unit at 09.00 hours on May 17, carried out strenuous military work all through a hot and brilliant day in an area where water was short, and developed symptoms of an urgent nature at about 18.00 hours. He died at 20.00 hours that evening. Post-mortem examination revealed no evidence of malaria or other infection. A most careful check was made, and there is no doubt that he had had a chalk pill. Of six other cases treated in medical units that day for "effects of heat," four proved to have infections (two coryza, one malaria, and one a superficial cutaneous infection); two were genuine cases of heat-exhaustion. One was a Sepoy, the other a British N.C.O.; neither of them had had any pill, active or inert.

From the results of the experiments it is concluded that hyoscine in the dosage employed (1/100 gr.) does not predispose to heat-stroke or heat-exhaustion among British or Indian troops carrying out full duty in assault exercises under tropical conditions.

3. Hyoscine and Military Efficiency

After the first few experiments various instances were brought to our notice in which men had apparently failed to carry out their duties efficiently, and the question of drug action arose. In one case an officer attributed his display of gross inefficiency to a pill he had had some hours before; it was shown that in fact he had had sodium bicarbonate. In other cases officers and men complained of feeling sleepy on landing in the early hours of the morning; in some cases a hyoscine action could not be excluded, though in others the pill given had been inert. It was soon apparent that there was a tendency among troops to ascribe to drug action any shortcomings in their behaviour during the exercises. On discussion with the officer commanding the troops in training, it was decided to make a large-scale test of the effects of hyoscine on efficiency rather than, as had been intended, to undertake a large-scale test of sea-sickness prevention.

Expt. VIII.—In each assault battalion (one British, one Indian) it was arranged to give hyoscine to one company, an inert pill to a second, and no pill of any kind to a third. The reserve battalion (Indian troops) were similarly treated. A smaller number of personnel of various artillery units were similarly subdivided, groups receiving respectively hyoscine, an inert pill, and no remedy. A supply of tablets of chalk, in shape and size approximating as closely as possible to the hyoscine tablets used, was secured for this experiment. The nature of the pills issued to individuals, companies, etc., was not known to anyone but us two.

The usual observations on sea-sickness incidence were made by R.A.M.C. observers, while detailed reports on efficiency of troops were called for from company and troop commanders, and from officers commanding units.

In this exercise a full-scale assault had to be carried out on beaches, with penetration inland over difficult hill country with scrub and bush. Troops were engaged in as nearly as possible battle conditions for a period of 36 to 48 hours. The experiment thus afforded a good test of whether hyoscine predisposed to the development of ill effects from heat or had any other effect on military efficiency. The reports from individual commanding officers, etc., may be summarized as follows:

Force Commander.—Generally speaking, the men were not seriously affected by hyoscine; some complained of drowsiness—as often as not those who had had the dummy pill. But one company of Pathans appeared to have been sleepy and incapable of reasonable action for an hour after landing; these men had had hyoscine. This same company had also complained of drowsiness on a previous occasion, when only one-third had had hyoscine.

Officer Commanding a British Battalion.—No complaint of inefficiency noted.

Officer Commanding an Indian Battalion.—One company commander complained that his men appeared "doped" on landing, and carried out an unusual manœuvre after disembarkation, earning adverse criticism in consequence. These were the Pathans referred to by the Force Commander. (It was later learned that their unusual manœuvre had been planned some days before the assault!)

Officer Commanding another Indian Battalion.—Reported signs of "dopiness" among men of one company on landing, which "wore off quickly once ashore." This company, unknown to him, had had hyoscine. It is to be noted that this battalion disembarked on a very gently shelving beach, and that the men had to cross a wide water-gap in wading ashore. This was considered by the umpires to have induced hesitation in disembarking.

Officer Commanding a Field Regiment and Anti-aircraft Battery (British Personnel).—No impairment of efficiency noted. In both these artillery units the experiment had been planned so as to include, in test and control groups alike, a number of individuals whose duties involved arduous physical labour or mental concentration.

The Commandant of the Training Centre stated that he personally did not consider that the remedies given interfered with the efficiency of the troops engaged. He stated that their performance compared very favourably with that of previous (and untreated) groups in training.

In considering the evidence it must be remembered that all the exercises in which excessive drowsiness was a source of complaint were carried out at night. Landings in general were at dawn, and the sea trips were made during the early hours of the morning after embarkation at or before midnight. Lack of sleep thus played a part in inducing drowsiness, as did the undoubted sleep-inducing effects of the motion of the craft. Further, such complaints as were received came from a relatively small section of the total subjects engaged, and the responsibility of the drug was not clearly established.

The balance of opinion, including that of senior officers observing the troops at work, was that untoward effects on military efficiency were not produced.

Summary

Experiments on the prevention of sea-sickness were carried out in the Tropics during the training of troops under conditions closely approximating those of battle. British (1,667) and Indian (3,673) troops were used for tests.

In all experiments, vomit-bags, sweets, biscuits, and chewing-gum were issued to all men taking part, and men were allowed to stand up in the craft if they so desired.

Assault craft of various types (L.C.A.s, L.C.M.s, L.C.T.s, L.C.I.(L.)s) were used for all but a few experiments in which 170-ton dhows were employed.

In all experiments control groups receiving inert pills were observed under conditions identical to those of the test group(s). Usually control and test groups were each of approximately 100 men.

The drugs tested and the number of observations on each were: hyoscine (1,990); hyoscine plus amphetamine (625); hyoscine plus ergotamine (116); chlorbutol (619); ergotamine (116).

After rejection of 2,102 observations rendered valueless by calm seas, etc., 3,638 remained for analysis. The validity of the results has been statistically assessed. A high degree of reliability is shown for those for hyoscine, hyoscine plus amphetamine, and for some chlorbutol experiments.

Of the remedies tested, hyoscine 1/100 gr. proved most effective. The degree of protection was of the order of four-fifths of those susceptible. This degree of protection was observed in relatively calm seas, when the sickness rate in controls was 16%.

No case of heat-stroke or heat-exhaustion occurred among 2,731 men who were given hyoscine. The average maximum and minimum temperatures during the experiments were 91.9° and 82.1° F., with an average relative humidity of 80%. Considerable physical exertion was performed by 1,789 of the treated men on assault exercises; a further 424 carried out a very strenuous assault during an exercise in which one fatal case of heat-stroke and two cases of heat-exhaustion occurred among 5,000 untreated troops.

The conditions of the tests were such as to reveal any impairment of military efficiency. Drowsiness in landing-craft was general in all experiments, in untreated as well as treated groups. Only on two occasions (and these involving the same men) was there a possibility that one company might have been adversely affected by hyoscine. Executive officers did not attribute shortcomings of the troops during exercises to the effect of any drug.

We are indebted to Lieut.-Gen. Gordon Wilson, C.B.E., *M.C.*, Director of Medical Services, General Headquarters, India, for permission to publish these results. It is a pleasure to record our appreciation of the co-operation and assistance so willingly given us by the Central Statistical Section of G.H.Q., India. Our thanks are also due to the officers commanding the training centre and the troops in training, as well as to their staffs, for the generous facilities afforded us and for the interest they displayed in the work.

HUMAN CREEPING MYIASIS

REPORT OF A CASE

BY

R. G. TURNER, M.B., B.Ch.

Formerly House-physician, University College Hospital, London

Very few cases of human creeping myiasis have been reported and none described very fully, so that the following case may be of interest to both physicians and parasitologists.

Clinical History

The patient (K. C., W.857), a boy aged 14, was admitted on Jan. 21, 1944, to University College Hospital. He lived in South London, and had the normal activities of a boy of his age. He had never been abroad, and had left home only for holidays at Brighton or Shoreham, where he used to visit the harbour; but he had not done this during the previous two years. He often used to go on Epsom Downs to fly model aeroplanes. He had no allergic personal or family history, but was sometimes bitten by insects and he whealed markedly as a result. His general health was good. Twelve months before admission he began having prickly pains over the shoulders and chest—"like a needle pricking the skin"—associated with aching pains in the shoulders and legs. These continued, without causing much inconvenience, in bouts about twice monthly for six months and then stopped. In July, 1943, he first noticed a swelling in the skin, not reddened, about 3 cm. in diameter, giving rise to a pricking pain on pressure but otherwise painless. It lasted two days and then disappeared. From then on he had many similar swellings, usually single, occurring at various sites (left calf, right popliteal area, left shoulder, back, and the back of the head and neck). They were 1 to 5 cm. in diameter and raised 0.5 to 1 cm. above the skin. They were red or skin-coloured, and caused a pricking pain on being touched, but did not throb. They usually remained for a few days and then disappeared, but the boy had from time to time the sensation of something moving beneath the skin, and he thought that the lumps sometimes moved, going down at one place and coming up near by at another.

On Dec. 30, 1943, one of these swellings came up on the right thigh, and in a short time showed a black spot in the centre. It was fomented, and on Jan. 2 burst, discharging sero-sanguineous fluid. The cavity was syringed by a doctor, and a white maggot emerged. At that time the boy had a severe sore throat, which subsided uneventfully. He was shortly afterwards seen at the Hospital for Tropical Diseases and found to have an eosinophilia of 54%. He was then referred to U.C.H., where his course was as follows:

Jan. 21, 1944.—On admission there were no swellings and the skin was normal. The patient was a sensible uncomplaining boy in apparently good general health. T. 98.6°, P. 104, R. 20, B.P. 115/80. Blood count: R.B.C. 4,800,000, Hb 100%, W.B.C. 22,000 (neutrophils 35%, lymphocytes 19%, monocytes 2%, eosinophils 44%).

Jan. 24.—Left temporal region painful (throbbing, worse on palpation), no swelling visible. During the night a swelling developed, and next day it involved all the left circumorbital tissues and the frontal region to the roots of the hair, extending just over the midline; it was tender, showed capillary pulsation, was oedematous, and pitted readily on pressure. The skin was reddened, with no circumscribed margin. The palatal fauces were reddened. Soft glands were palpable in left axilla and on right side of neck. Attempts to obtain fluid from the swelling were unsuccessful. T. 103.6°, P. 108, R. 24, in the evening. Blood culture negative. Radiograph of chest negative.

Jan. 27.—Oedema spreading; left eye practically closed. Adrenaline (0.25 c.cm. of 1:1,000) given subcutaneously with doubtful effect. The oedema then gradually subsided and was gone by Feb. 4, as was also an irregular spiking temperature, present since admission. Urine normal. Stools negative for ova and parasites.

Feb. 6.—In the night the patient developed tenderness over the 7th left rib in the mid-axillary line. At 7 a.m. there was in this situation a small red non-indurated slightly tender raised area, 2 by 1 cm., with a central clear yellowish linear bleb. This was incised, and from immediately below the skin a white segmented maggot, very slightly motile, 1 by 0.3 cm. in size, was shelled out. Temperature 97.4°. The maggot was taken to the London School of Hygiene and Tropical Medicine, and identified by Dr. John Smart of the British Museum (Natural History) as the larva of the warble-fly (*Hypoderma bovis*) in the spineless stage (first instar, according to Knipling's (1935) description).

Feb. 8.—A similar swelling, but with a small dark spot in the centre, was present on the right medial malleolus. It was fomented; but by 8 p.m. the dark spot had disappeared, the swelling being otherwise unchanged. During the day four pink papules, 4 by 1 mm. in size, appeared in a straight line on the front of the left side of the chest, as though distributed along the 4th intercostal space. One of them was opened, but no maggot was found. Blood count: W.B.C. 20,800 (N. 30%. L. 24%, M. 2%, E. 44%). Erythrocyte sedimentation rate, 12 mm. in 1 hour. During the next five days the papules disappeared.

Feb. 13.—A reddish smooth swelling developed over the medial edge of the right scapula. The patient thought it was one of the papules that had migrated. Next day this swelling had disappeared, but one had come up in the right lumbar region, and the patient thought this also was a migration of the same swelling. *Feb. 15.*—No swellings present.

In the next three weeks, except for a spike to 101.2° on Feb. 16, the patient was afebrile and asymptomatic. Several swellings, similar to that of Feb. 6, developed, and three more specimens were obtained from the left buttock and the right lower leg—one excised and two forced out with ease by squeezing. The small central bleb noted on Feb. 6 was not again seen, but a few swellings showed the dark central spot observed on Feb. 8. Some of them were not touched, and it was noticed that the dark spot would spontaneously disappear in a few hours, though the surrounding swelling generally lasted for one or two days. *Feb. 24.*—Blood count: W.B.C. 20,000 (N. 24%, L. 17%, M. 2%, B. 1%, E. 56%).

No swellings or oedema developed after March 1. On March 7 the patient had a sore throat, which was reddened, and the right anterior cervical glands were swollen. There was no fever and the throat culture contained no pathogens. Symptoms subsided in a few days, and the patient was discharged on March 10. He has had no symptoms or signs since; he was last heard from on Feb. 22, 1945.

Commentary

Cattle are the usual hosts of *Hypoderma* flies, which are usually one of two species—*H. bovis* and *H. lineata*. Great economic loss results, on account of the damage caused to the hides by the emerging larvae. The flies are said (Herms, 1939) to occur throughout the U.S.A., Europe, and Asia. So far as has been ascertained, the adult fly usually lays her eggs on the legs of the host, and this often terrifies the animal, which may plunge about in a frenzy, or rush into water, in an attempt to dislodge the fly. The egg hatches in about a week, and the larva penetrates the skin directly or via a hair follicle. This process, in those cases observed in man (and presumably in our case), is painless. Once inside the host the larva moves about, usually among the viscera, and especially between the muscular and mucous layers of the oesophagus. In autumn, winter, or spring it migrates through the muscular tissues of the back to lie under the skin, through which it bores a hole for respiration. It then moults, and during this time a local purulent reaction develops, causing the "warble," which finally bursts, to allow the larva to fall out and pupate on the ground. The warbles are sometimes treated locally by farmers with derris or phenol.

Cases of human infestation by the warble-fly *Hypoderma bovis* are very rare, and I have found only five in the literature (Herms, 1939; Miller, 1910; Smart, 1939). A case involving the allied species, *H. lineata* (Style, 1924), was probably the first British case of infestation of man by a species of *Hypoderma* to be reported. In our case the boy's sore throat may have been caused by wanderings of the larvae in the oesophageal wall, especially as his pharyngeal flora showed no pathogens at the time. It is hard to be sure when the eggs were laid; the emergence of all the maggots during a period confined to about two months suggests that he was infested only once, or, at any rate, during one season only. This most probably was during the summer of 1943, perhaps while he was asleep on Epsom Downs. The manifestations seem to have been due partly to an allergic response (causing oedema and eosinophilia) and partly to the bodies of the larvae themselves. As the case stands it is impossible with certainty to say whether the larvae migrated in the patient or whether they emerged where oviposition occurred, as has been noted in infestation by other species (Herms, 1939, p. 354); though in view of their widespread distribution over the body, the sensation of "creeping," and the apparent surfacing and sinking of the larvae in the swellings, it seems likely that migration did take place.

I wish to make acknowledgment to the late Sir Thomas Lewis and Prof. P. A. Buxton for their help in preparing this report.

ABACTERIAL PYURIA

BY

HUGH DONOVAN, M.B., F.R.C.S.Eng.&Ed.
Honorary Surgeon, United Hospitals, Birmingham

There exists a condition, provisionally called by the unsatisfactory name of "abacterial pyuria," which is quite well known to urologists, but which is not sufficiently known to medical men as a whole. Of the 15 or so cases which have come under my care in the last six years, one was that of a doctor in full practice who was troubled for months with the condition until the diagnosis was made; another that of a young man who was invalided out of the Army, diagnosed interstitial cystitis; a third was a soldier sent home from the Western Front. It is because of such cases that the following account of the condition is given.

The patient, an adult male, begins to suffer from very frequent and uncomfortable or painful micturition. There may be some associated urethritis sufficient to stain the linen. The urethritis is not constant, and does not precede by much, if at all, the bladder symptoms, which are often the main and only complaint. Fever has not been recognized. At this point the man, if he has a urethral discharge, will be examined for gonorrhoea. The negative bacterial report will probably result in his being given a pot. cit. mixture and a pat on the shoulder—but his frequency will continue. The two-glass test shows an equal amount of pus in the second glass. Heavy treatment with sulphonamides brings no result. The urine is examined bacteriologically, but fails to show organisms in a specimen full of leucocytes. At this point tuberculosis of the urinary tract is suspected because of "pus in a sterile urine." Intravenous urograms show a normal upper urinary tract. Cystoscopy reveals a bladder too irritable for really good examination, but shows a complete cystitis and an angry red mucosa with no portion of the bladder wall uninvolved. A guinea-pig inoculation test for the tubercle bacillus is of course negative.

The above clinical picture warrants a provisional diagnosis of the disease. It is remarkable, and fortunate, that a specific and apparently infallible remedy is to hand. 0.3 g. of neoarsphenamine, given once a week, will improve the condition after two and will apparently cure it after three injections. I do not think I have seen a relapse yet, nor have I observed any systemic complications.

When one has surmounted a natural disinclination to accept a new disease, one begins to recognize peculiarities which make diagnosis easier. A purulent urethritis of non-gonococcal causation is itself rather unusual. When it is associated with marked frequency and a cloudy second glass of urine the disease must be definitely considered. When no organisms, or only a few colonies of an obvious contaminant, are reported in this urine full of leucocytes, there is a strong probability of the condition being present, for tuberculosis of the urinary tract is associated with urethritis with extreme rarity. Moreover, it is not so sudden in its onset, and the urine is as a rule only moderately cloudy. The completely red bladder is not at all like that of tuberculosis, in which there are practically always some areas of bladder almost normal in appearance.

Discussion

Moore (1943) has dealt with the pathology of the condition and with the various views as to its aetiology. My own preference is for the theory that it is caused by a virus—after all, the commonest cause of mucous surface infection in the body. Probably the pathogenic agent will remain unproved until Koch's postulates can be established by human experiment.

There has been recognized of recent years, and especially since the war, a subacute or chronic epididymitis often with little or no evidence of urinary infection. I do not think this can be related to abacterial pyuria, a striking feature of which is the failure of the urinary infection to respond to most forms of treatment.

I have not met with the condition in the female. It is reasonable to ask the question: Is there a vaginitis or cervicitis of similar causation and likely to respond to intravenous neoarsphenamine?

If the cause of abacterial pyuria is a virus, response to organic arsenic is worthy of attention. If one may be permitted to speculate a little—Domagk found prontosil to cure certain streptococcal infections. Subsequent experimental work produced sulphonamides with effect on other organisms. It would seem worth while re-examining some of Ehrlich's 606 original arsenicals and others, and trying some of them on smallpox, typhus, yellow fever, influenza, etc.,

Abstract of Some Typical Case Histories

D. B. G., aged 40.—First seen May 8, 1941, complaining of five months' painful frequency; some discomfort in the left loin. The urine was cloudy, and contained leucocytes and red blood cells; no organisms; guinea-pig inoculation negative for tubercle. Radiograph—no abnormal shadows; intravenous pyelograms normal. Cystoscopy revealed an intolerant bladder. Indigo carmine came equally and well from the ureters. Three injections each of 0.3 g. N.A.B. were given. On Aug. 15 the urine was clear; a cell was present in only three or four low-power fields.

D. A., aged 49.—First seen April, 1939, complaining of five weeks of frequency and scalding, with the passage of blood. The urine was cloudy; it contained a faint haze of albumin, and microscopically showed degenerate leucocytes. Cystoscopy revealed cystitis; indigo carmine came equally and well. The ureters were catheterized, specimens showing no excess of white blood cells. The laboratory report on the urine was: leucocytes; no organisms. Guinea-pig inoculation was negative for the tubercle bacillus. After the usual three injections of N.A.B. the patient improved, and in June his urine contained a doubtful thread. There was an occasional cell in the first glass; the second glass was clear.

Medical Practitioner, aged 52.—First seen March, 1942, complaining of a urethral discharge, with urgency and frequency of three months' duration. A film had been examined for gonococci, with negative results. Intensive sulphonamide treatment had been given without benefit. The urine (glasses 1 and 2) was cloudy. It contained no organisms in the film. No gonococci were obtained after culture with CO_2 enrichment. The gonococcal fixation test was negative. The usual three injections of N.A.B. were given, and the patient wrote on April 15 to say that he had no urinary symptoms; his urine was clear, and contained no albumin.

T. B., aged 51.—First seen on Nov. 22, 1944, complaining of frequency, every 20 minutes by day and five or six times by night, with some terminal haematuria, of two weeks' duration. The urine was cloudy, contained albumin, and microscopically leucocytes and red blood cells. Cystoscopy revealed a haemorrhagic cystitis. Blue came equally and well from the kidneys. The laboratory reported leucocytes but no organisms. After three injections of N.A.B. he lost his discomfort, and on Jan. 26, 1945, his urine, which was clear, contained a very faint haze of albumin and no leucocytes on microscopical examination.

A. D., aged 35.—First seen Oct. 27, 1944, complaining of frequency and haematuria of sudden onset two weeks before, with pain. The urine contained leucocytes. On cystoscopy the bladder was intolerant and intensely congested. The laboratory reported on the urine on Nov. 2: leucocytes, and on microscopical examination a few Gram-negative bacilli. On Dec. 15 the report on the urine was: leucocytes; no organisms. After three injections of N.A.B. the patient's symptoms were cured; and on Jan. 26, 1945, his urine contained no albumin, and nothing abnormal was seen on microscopical examination.

Moore, Thomas (1943). *J. Urol.*, **49**, 203.

At a summer school in social biology which the British Social Hygiene Council is to hold in the Hugh Stewart Hall of University College, Nottingham, from July 28 to Aug. 11, interest will be directed chiefly to problems of education and social life likely to arise through the coming increase in the school-leaving age. The director of the school is Prof. Winifred Cullis, D.Sc. The course is open to all types of teachers, social workers, and members of the general public interested in education and social problems from a biological aspect. The morning lecture programme has been planned to illustrate the aims and content of social biology. Courses of lectures will be given on the place of biology in education, the biological approach to personality, the social aspects of health, the contribution of natural history to social biology, and food production and nutrition. Dr. Mary Collis and Dr. A. C. Tibbits will give an account of the successful scheme of sex-education which they have helped to set going in schools in Nottinghamshire, and this will be followed by a discussion of the technique of sex-instruction in school. At the evening sessions lectures will be given by visiting speakers on the broader application of biological knowledge to human life and culture. A programme of excursions and visits to places of scientific and general interest has been arranged. The inclusive fee for the course is £12 12s. (enrolment fee £1 1s.) and early application should be made to the secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

NOTES ON ADDER-BITE (ENGLAND AND WALES)

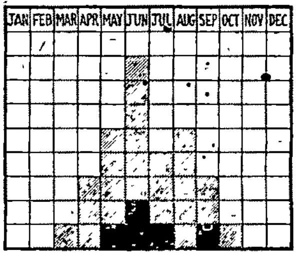
BY

C. W. WALKER, M.C., M.D.

(Herefordshire General Hospital)

The following notes are based upon accounts of 50 cases, some of them already recorded, the remainder kindly sent me by doctors in many parts of England and Wales in response to a query published in the *Journal* (July 25, 1942, p. 118). Others have been obtained from patients themselves. The aim of the inquiry was to provide an answer to the question, "How serious is adder-bite?"—a question of some interest in view of our complete lack of a specific *V. berus* antivenene, or indeed, since 1940, of supplies of European viper antivenene of any kind.

The adder (*Vipera berus*) is our only poisonous snake. It is common in many parts of the country, though seldom seen owing to its shyness. It hibernates during the colder months, and is seldom in evidence even in summer, unless the day be warm and sunny. It is commonly believed to be most venomous in spring, but in the present series severe bites occurred throughout the season March to October. The diagram shows the month of occurrence of the dated cases; each lightly shaded square represents a case; the darker squares represent the five fatal cases. It is plain that high summer is the season of maximum danger from adder-bite.



Graph showing seasonal incidence of adder-bites in present series.

Situation of Bites.—The bites were all situated distally on the extremities,[1] three-quarters of them being on the hand, the remainder on foot, ankle, or calf, and one on the brow. The most usual sites were a finger (especially the index) or thumb. There was no apparent connexion between the position of the bite and the course and severity of the reaction, except that in the case of the man bitten on the brow collapse was early and complete and unconsciousness of long duration.

Clinical Features

The effects of the bite are general and local. The general reaction, which takes the form of shock or collapse, varies greatly in degree in different cases, whereas the local reaction is more constant, the bitten limb in nearly every case showing massive oedema up to the trunk and haemorrhagic discoloration, usually most pronounced in the neighbourhood of the main lymphatic trunks. The oedema as a rule spreads up the limb to the axilla or groin within six hours, but continues to progress in intensity generally for two days or so, and in severe cases to advance to some extent over the trunk or head.

The general reaction varies between the very slightest malaise on the one hand and profound collapse on the other. About half of the cases were severe enough to occasion real anxiety for the patient's life. In most cases the critical period was of brief duration, the patient being out of danger within 12 hours; but some remained critically ill for several days. Within 20 minutes of the bite the patient begins to feel faint and giddy, or experiences a sensation of constriction of the head; young children begin to be drowsy, and soon become semiconscious. Nausea occurs, and vomiting is usually a prominent feature and may last for days; there may be haematemesis. Colicky pains may occur, and diarrhoea is present in a quarter of the cases. Swelling of lips, face, and tongue is common, or there may be tightness of the throat, severe thirst, difficulty in breathing, or pain attributed to the heart. With the above symptoms collapse sets in. The patient is pale and cyanosed, cold, sweating, and semiconscious or unconscious. The pulse is rapid and thready, often almost or quite impalpable. The pupils may be widely dilated.

Fear may, as is often claimed, play a part in the causation of the early "shock," but it may be completely absent, as in the case of patients who are unaware they have been bitten and have not seen their assailant. As regards the prolongation of the collapse stage, it is important to note that the severe and prolonged vomiting and diarrhoea, the sweating and the massive localized oedema, are all factors in producing a state of dehydration, important from the therapeutic point of view.

It is commonly at this stage, two or three hours after the bite, that the patient is first seen by a doctor. In most cases by this time the oedema and discoloration have progressed some distance up the limb, and the site of the bite, at first painless, is beginning to be painful. In collapsed patients the swollen limb is often described as being very cold and blue, or even black. Collapse symptoms pass off as a rule about six to eight hours after the bite, and the temperature rises from subnormal to 101 or 102°. This rise may be brief, or slight fever may last from a few days to a week. Diminution of urine is noted at this stage: in one severe case there was anuria for three days. Cardiac depression occurs, evidenced by slow pulse and low blood pressure.

The swelling and haemorrhagic discoloration of the bitten limb increase in extent and intensity for one to three days, and then gradually decline, the various colours of a bruise being manifested. Tenderness is marked, but there is comparatively little pain as a rule; on recovery pain is felt on moving the joints, and there is extreme muscular weakness. In no case was there any septic complication or gangrene. The prevailing fear of the latter sequel appears to be groundless, and is based, no doubt, upon memories of the past, when strong ammonia and other harmful caustics were commonly used in treatment.

Immediate Prognosis and Course of Illness

The most important factors governing the severity of the general reaction appear to be the size of the adder, the age and health of the patient, and the rapidity and correctness of the treatment. As regards age, of 12 cases in subjects under 12 years old all except two were severe. In the "teens" and young adults mild, moderate, and severe reactions occurred in about equal proportions. Of seven cases in persons over 45 years old five were severe.

The age of the patient has a marked effect upon the duration of the illness and disablement. Children, adolescents, and young adults recovered within a fortnight; the only exceptions other than fatal cases were one child whose swelling had not disappeared in four weeks, and another (my own case) who, on first using his bitten leg after 17 days, ran a temperature of 102° for about 24 hours and had symptoms similar to those noted at the onset, as though dormant venom had been liberated into the circulation by movement of the part. In middle-aged and elderly patients resolution is slower. A woman aged 54 had a swollen ankle for three months; a man aged 45 had a swollen arm for over six weeks; and a man aged 57 had some swelling for over a year, then suffered for many months from a stiff and painful shoulder and could not close his fist properly for months after the swelling had subsided. A gamekeeper "nearly lost his life and could not work for at least a year"; a lady states: "It was about six weeks before I could walk properly."

Remote Prognosis

Recovery appears to be complete and without serious after-effects. Dr. Stradling wrote: "Many bitten persons who have recovered from all primary symptoms produced by the poison eventually succumb to its influence, in remote and indirect effects, at a later period," but I have been unable to find evidence to support this view. Four severe cases have remained perfectly well and suffered no after-effects after a lapse of 13, 16, 23, and 24 years respectively since their bites. Two men, severely bitten in youth, have now reached 79 and 81 years of age without observing any after-effects. I have many reports of perfect health for shorter periods.

A doctor aged 60, bitten by very young adders, had only the slightest reactions at the time, but developed endarteritis two years later; he attributed this to his bites, but I gather that medical opinion was divided on the subject. Another doctor, middle-aged, shed all his finger- and toe-nails a year after being bitten, but suffered no other inconvenience and lived to the allotted span. One adult male states that he still, after six years, experiences some swelling and discoloration in the bitten hand each autumn; a woman bitten over 20 years ago still has similar slight local recurrences of oedema. Another man developed phlebitis, starting at the situation (in the leg) where he had been bitten eight years earlier.

Fatal Cases

There have been seven deaths from adder-bite in England and Wales in the last 50 years. I have been unable to trace two of these. The five remaining subjects were aged 11, 4½, 6, 3, and 51 years respectively. The principal features in these cases may be tabulated thus:

No.	Sex	Age	Previous Health	Duration (hours)	Mode of Death
1	M	11	Delicate	12	Collapse; cardio-respiratory failure; conscious
2	M	4½	Healthy	60	Circulatory collapse; unconscious
3	F	3	,,	6	,, ,, ,,
4	F	6	Delicate	36	,, ,, ,,
5	M	51	Insane W.R.+	26	Unconscious, with T. 102°, bounding pulse, and stertorous breathing

Note.—None of the above received antivenene serum.

Summary of Conclusions

The danger of adder-bite is greatest in high summer. Its clinical features are: (1) a local spreading haemorrhagic oedema; (2) a general reaction of very varying degree, from slight weakness to profound collapse.

About 50% of the cases give rise to real anxiety. In young children the "shock" reaction is severe; in the "teens" and young adults mild, moderate, or severe in equal proportions; in persons over 45, generally severe. Children, however, recover much more quickly than adults. Recovery is complete and without after-effects.

Fatal cases are rare, but death can occur even in quite healthy young children. In the fatal cases, none of which had received antivenene serum, death occurred in from 6 to 60 hours.

My thanks are due to all those doctors who have kindly supplied me with reports of their unpublished cases of adder-bite; also to many bitten persons who have supplied data otherwise unobtainable.

Medical Memoranda

Allergy to Moulds in England

In a paper on moulds and asthma (Fraenkel, 1938) I compared skin reactions to a mixed mould extract from *Penicillium, Aspergillus,* and *Mucor* types of moulds in Germany and in England. It was found that 16% of the asthma patients tested in Germany gave positive reactions to this allergen, whereas asthmatics tested in England gave 53% of positive reactions to the same mixture.

It has become evident from the American literature on mould allergy that regional differences in the incidence of positive reactions to moulds have been observed in the U.S.A. Balyeat found in Oklahoma positive reactions to moulds in only 1% of his patients; 12.2% were obtained in Los Angeles by Lamson and Rogers. They used extracts supplied by the Arlington Company, made up from four types of *Aspergillus* and of one type each of *Alternaria, Chaetomium, Monilia, Mucor,* and *Penicillium*—in all, nine different types. Feinberg, in Chicago, obtained 28% positive reactions towards one or more of several fungi.

Another paper was published by Schonwald from Seattle, and this author observed that 77% of his patients gave positive results to one or the other of 10 types of moulds. Schonwald stressed the point that there is a far more abundant growth of moulds in Seattle, with an average humidity of 85% in the morning and 51% in the evening, compared with average humidities of 42% and 27% respectively 300 miles inland. These facts explain the great part played by moulds in the aetiology of asthma in this district of the United States. His views were confirmed by the success of desensitization treatment with mould extracts in 86 patients.

The moulds are an important factor in hay-fever and in asthma because of the abundance of mould spores in the atmosphere and because, being much smaller than grass pollen, they are more easily inhaled and absorbed. They are present indoors and out of doors, particularly in a damp climate like that of England, and in many cases are probably responsible for the fact that an allergic patient is ill in one particular district, house, or room. Mould-infested beddings, feathers, mattresses, or even kapok can become the cause of asthma or other allergic complaints, just as the *Cladosporium fulvum* Coke on decaying tomato plants causes asthma in gardeners, or moulds in cheese cause other allergic irritations.

These observations seemed sufficient reason to study allergy to moulds in this country more closely. In my first investigations I was aided by Miss Frances Stephens, of the Natural History Museum Department for Mycology. I learned that there are probably more than 1,200 different types of moulds to be found in this country, and that culture of moulds, identification, and classification are often not easy (Fraenkel, 1939). The task is not made easier by the fact that they are able to form cross-breeds, with apparently new characteristics.

Out of that abundance of moulds it seemed advisable to choose for further investigations those which were likely to be most important as allergic factors. It was presumed that moulds which were found in closest contact with the body of allergic patients would probably be more important than others. In 40 cases of allergy, mostly asthmatics, but also cases of vasomotor rhinitis (including hay-fever), of eczema or urticaria, and of migraine, moulds were cultured from the patient's environment (dust, beddings, etc.) and excretions (sputum in asthma, nasal swabs in rhinitis, and faeces in skin cases). In a great number of cases identical moulds were found in both excretions and environment. Extracts of these were used for skin tests in the patient, and where these gave positive reactions the allergens were also employed to desensitize him. Pure cultures of moulds and extracts were kept in stock. The results of this method were encouraging, but the number of patients examined and treated was too small to justify final conclusions. A great deal of material and of assistance was required for the mould cultures, and I wish to thank Mr. F. R. Hackett, of the Southern Group Laboratory, for the help he gave me in this investigation. In the course of the war it became increasingly difficult to carry on the investigations when work of greater importance had to be given preference. It was therefore decided to use the six types of moulds most frequently found in our allergic cases as stock allergens for skin tests and for desensitization.

180 allergic cases have so far been tested with these six types of moulds, which had been isolated from the environment and from the excretions of allergic patients. Of these, 120 were asthmatics, 30 were cases of vasomotor rhinitis (including hay-fever), and the others cases of urticaria, eczema, and migraine. The first 100 cases of asthma were evaluated statistically, as the number of other cases so far examined was considered too small for such purpose. They have all been subjected to scratch tests to allergens from the following types of moulds and to a mixture of these in equal parts: (1) *Sporotrichon*, (2) *Cladosporium*, (3) *Penicillium*, (4) *Aspergillus*, (5) *Mucor*, (6) *Monilia*.

Table showing Results of 100 Cases of Bronchial Asthma tested with 6 Types of Moulds

	Positive (%)	Negative (%)
With mould mixtures ..	66 (++14; +52)	34 (±6; −28)
„ Sporotrichon	65 (+++1; ++25; +39)	35 (±6; −29)
„ Cladosporium	53 (+++2; ++19; +32)	47 (±5; −42)
„ Penicillium	44 (++8; +36)	56 (±4; −52)
„ Aspergillus	39 (++9; +30)	61 (±5; −56)
„ Mucor	40 (++12; +28)	60 (±5; −55)
„ Monilia	31 (+++1; ++8; +22)	69 ±4; −65)

The mould mixture gave the most frequent positive reactions, as could be expected; next to it came *Sporotrichon* types, with 65%, and *Cladosporium*, with 53%. Of the cases examined 44% gave positive reactions to *Penicillium*, 40% to *Mucor*, 39% to *Aspergillus*, and 31% to *Monilia* types.

The results obtained are very near to Schonwald's figures as reported from Seattle, the geographical position of which on the American continent is similar to that of England in Europe. It can be presumed that climatic conditions, especially humidity of the air, dampness of the ground, and consequently growth of moulds, are also somewhat similar.

From these observations it may be justifiable to draw the conclusion that allergy to moulds cannot be neglected in the examination and treatment of asthmatics or other allergic patients in this country.

Reviews

PREVENTION OF VENEREAL DISEASE

The Prevention of Venereal Disease. By L. Martindale, M.D., B.S., F.R.C.O.G. (Pp. 74. 2s. 6d.) London: Research Books, Ltd. 1945.

This little book is presumably written mainly for the general public, but it should also prove of interest to social service workers. The first part is devoted to an account of the three main venereal diseases, their symptoms, diagnosis, and treatment; the author makes the common mistake of stating that cold may kill the gonococcus, the very doubtful statement that syphilis can be transmitted to the 3rd and 4th generations, and slips up when she says that gonorrhoea is treated with penicillin for a total of 60 injections in 7½ days. Part II includes chapters on earlier experiments in legislation, an account of the success of the clinic system in Great Britain, war and legislation, notification, what Russia has achieved, and a final chapter on conclusions to be drawn. There are four appendices—the report of the Trevethin Committee, notification and compulsory treatment in various countries, a list of V.D. clinics in Great Britain (which incidentally is not up to date), and the Oath of Hippocrates.

Few will quarrel with the theme that runs through the book—that continence is the one sure way of avoiding V.D., that the problem is a moral, just as much as, or possibly more than, a medical one, and that education of the public to make it V.D.-conscious should be the main plank in the anti-V.D. platform. Miss Louisa Martindale is a stout opponent of any form of compulsion, and has nothing good to say for Regulation 33B, which, however, has hardly been the failure she would suggest if account is taken of the results of acting on a single notification. Recommendations include sex instruction, cleaner films and a higher standard of literature, better housing and living conditions, healthy recreation, improved treatment facilities, and more almoners; nothing is said about case finding, which has given very good results where it has been undertaken with energy and tact.

SETTING A COURSE FOR CONDUCT

Thoughts, Deeds and Human Happiness. By K. W. Monsarrat. (Pp. 123. 7s. 6d.) Liverpool: The University Press. 1944.

Three years ago Mr. Monsarrat published *My Self, My Thinking, My Thoughts,* which was an analysis of self-expression. In the present volume he further examines human view-forming powers and habits—a design for living and how and by what action the social desires and aspirations of men may be fulfilled. In his introduction he refers to the present war as employing the greatest number of men that the nations can muster, and all the means that ingenuity has devised and industry can produce to kill or maim each other. Always there have been men who have been antagonists of their own kind and have chosen the robbing of others of their lives or of their chances of happiness as a means for contriving their own advantage. Mr. Monsarrat says: "It is not certain that the human race is inevitably condemned to recurring orgies of mutual torture and murder, but it is certain that it will have to find a new way of living wholly different from that which has been its habit, coupled with new views, valuations, and beliefs, if it is to escape them."

Each of us desires his own stability and prosperity; the only way to ensure this is by giving these benefits to others, supplying their needs and adding to their wealth. In developing his thesis of a design for living (albeit with some tautology) the author stresses that the effort by men to acquire good states *for themselves* always brings them to the brink of social ruin. Most of the book is occupied with the question of planning what we desire and the best principles of behaviour. There is a good chapter on self-expression and the means to understanding. Sense and intelligence are the keynote of this book—the word "sense" being used for that ability which gives a man a "view" or picture, and the word "intelligence" for his habit of interpreting his "views" in terms of actions that have brought about what the views show. The volume is thought-provoking and contains the foundations for believing in and following the right course of human conduct. It is, after all, a scientific enunciation of the Christian doctrine.

SUR[illegible]L ERRORS AND SAFEGUARDS

Surgical [illegible] and Safeguards. By Max Thorek, M.D., LL.D., F.I.C.S. With foreword by Sir Hugh Devine, M.S. And a chapter on Legal Responsibility in Surgical Practice by Hubert Winston Smith, M.D. Fourth edition, completely revised. (Pp. 1,085; illustrated. 90s.) London: J. B. Lippincott Company.

This book by Max Thorek is now very widely known; the present, fourth, edition is enlarged to well over a thousand pages, and, as the author says, is a "compendium of the experiences of surgeons throughout the world" instead of being in the main a guide derived from personal experiences. As a result the work is more valuable and considerably expanded. To those who are not acquainted with the scope of this work it should be pointed out that the title is a little misleading in that it is much more than a mere recital of the pitfalls of operative surgery; many operative procedures are fairly fully described, and there is an abundance of information upon the value of diagnostic signs and symptoms. Indeed it might almost be considered to be a textbook of surgery, laying emphasis upon the mistakes which may be made.

The book is well produced, and the illustrations, nearly 800 in number, are of the excellence usually associated with Thorek's writings. When reviewing the original edition we drew attention to the unfortunate use of certain expressions which, while probably well recognized in the United States, are not understood elsewhere. The particular instance which we then picked upon—"Do not operate upon cases of frozen pelvis"—still remains in the text, and although thirteen years have elapsed we still do not know what it means. The volume, however, is one which can be strongly recommended for the perusal of the surgeon, be he young or old, about to deal with a type of case in which he is not as yet very experienced; it can be relied upon to have the chastening effect which is the author's aim.

Notes on Books

Welfare in the British Colonies, by L. P. MAIR, is published at 5s. by the Royal Institute of International Affairs (Chatham House, St. James's Square, London, S.W.1). This study of our various Colonial welfare services describes how the aims of social policy are put into practice. Education, labour, and health are the three subjects for which the Colonial Office employs specialist departments. Africa, Malaya, Hong Kong, the West Indies, and the Western Pacific Islands are the far-flung spheres, and the work done in one reacts upon that in every other. Great problems have had to be faced. This booklet shows that none are insoluble and that wonderful work is being done to adjust vast native populations to modern conditions. An all-round increase of welfare must greatly depend on improvement of health conditions, especially in the Tropics, where parasitic infections are much more prevalent than in Europe and have widespread debilitating effects. It is now recognized that the apathy and lack of initiative of Colonial peoples are much more likely to be due to their physical condition than to any quality inherent in their character, and emphasis is now shifting from the curative to the preventive aspects of tropical medicine. This calls for the co-operation of all experts in the tropical field. Mr. Mair has compressed into small compass a great deal of useful information that will give good guidance to intending Colonial medical officers.

Convalescence often passes through two phases; the first is pleasant to the patient, who daily feels progress is being made without effort or responsibility on his part. But as this rate of progress slows down, and the patient becomes less "interesting" to his attendants while having to revive his own resources, a period of disappointment is apt to ensue. It is with the treatment of this second phase that Miss SHEILA PIM's perceptive little book *Getting Better* (Faber and Faber; 6s.) deals; it is mostly addressed to the convalescent himself, and is full of useful hints of methods to avoid boredom and facilitate recovery, adapted to all grades of intelligence.

The shortage of nursing and domestic staff in tuberculosis institutions has prompted the Ministry of Labour and National Service to reissue for general circulation a small pamphlet, *The Healing Touch*, originally compiled by the National Association for the Prevention of Tuberculosis. This is designed to encourage recruitment for sanatorium nursing.

Correction.—Two mistakes appeared last week in the notice of the fourth edition of Dr. W. GORDON SEARS's *Medicine for Nurses*. The publishers are Messrs. Edward Arnold and Co., and the price is 10s.

Preparations and Appliances

APPARATUS TO ELEVATE A FRACTURE CASE FOR APPLICATION OF PLASTER

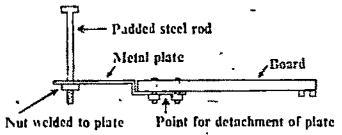
Fl. Lieut. J. NOEL-JACKSON, M.B., B.S., writes:

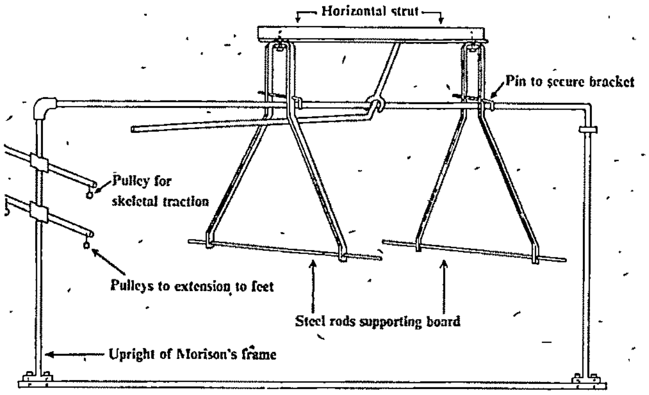
During the snowstorm in March, a man aged 76 fell near his home in an isolated village. On examination there was deformity of the left thigh and marked shortening. His condition of grave shock precluded the uncertain journey to hospital. The village was virtually cut off by the appalling weather and no appliances were available.

A Thomas splint was fashioned from steel rod and welded in a garage near by. Skin traction was applied and the patient put to bed. The general condition did not improve, and it was apparent that he required a more comfortable extension. A form of ice-tong calliper was designed. This had to be extremely simple because it had to be made without special skill. It consists of two pieces of 5/16-in. section steel rod tapered to a point at one end, flattened for 1 in. at the middle and at the other end, where a hole was drilled through it. Both were then bent to form a modified "S" as in the diagram. The two halves were then bolted together.

A Braun frame was made from steel strip, and skeletal traction fitted up. Application of a plaster cast without releasing the extension was the next problem.

A Morison gas-pipe frame was made up of 1½-in. steel tubes. Two inverted "V" brackets were made. These were to fit over the overhead beam of the frame suspending the patient clear of the bed. The brackets supported a board slipped under the patient's back. Horizontal cross-pieces were bracketed to the upright of Morison's frame to take pulleys for extension. When it was decided to apply a plaster cast the first step was to slip a flat board under the patient's back. This extended from the head to the level of the second lumbar vertebra. A metal plate was bolted to the lower end of this board. This plate could be detached from the board by unscrewing four nuts.





Horizontal strut
Pin to secure bracket
Pulley for skeletal traction
Pulleys to extension to feet
Steel rods supporting board
Upright of Morison's frame

The "V" brackets were then fitted to the overhead beam. Two steel rods were slipped under the board and through holes drilled through the lower end of the brackets. The extension was transferred from the Braun frame to a pulley on the upper horizontal cross-piece. The Braun frame was then removed and traction applied to both feet over pulleys at each end of the lower horizontal cross-piece.

A padded steel rod threaded at the lower end was screwed into the metal plate to provide counter-extension in the groin. The upper ends of the brackets were connected by a horizontal strut. A lever applied near the middle of this lifted the patient clear of the bed.

As the application of the cast proceeded the skeletal traction was removed. It should be observed that without the support of the Braun frame the leg took up an attitude of extension at the knee-joint due to the weight of the leg. Finally the patient was lowered, the board was detached from the metal plate by unscrewing four nuts, and the board slipped out sideways. The metal vertical rod was unscrewed from the metal plate and the latter withdrawn by pulling it upwards. Extension to the feet was removed.

The entire apparatus was designed to meet a novel and unforeseen emergency, and it is worth recording only because the entire apparatus was made with materials available almost anywhere. A skiagram taken some weeks after the injury shows an oblique fracture through the greater trochanter of the femur. Union is poor but apposition is excellent. The poor bony union vindicates the precautions taken to ensure continuity of extension, but the position achieved at least favours union and avoids shortening, and the patient is now walking about.

I am indebted to Mr. Exton, of Wheatcroft, for the incredible promptness with which the apparatus was reproduced from my brief drawings.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 7 1945

THE ORGANIZATION OF THE MEDICAL PROFESSION IN WARTIME

We are privileged to print in this week's issue at page 22 a letter from the Minister of Health (Mr. Henry Willink) paying generous tribute to the work of the Central and Local Medical War Committees during the past six years. We are sure that the members of these committees and the profession generally would like us, in response, to acknowledge the friendly and helpful spirit of co-operation not only of Mr. Willink and his predecessors in office but also of the other Ministers, Government Departments, and the fighting Services who have needed and used the service of the profession throughout the war. During these strenuous years many things have been done, often under a shroud of secrecy, which easily slip the memory, and it may therefore be appropriate at this time to recall some of them.

As far back as 1925 the Council of the British Medical Association, actuated by its experience of the war of 1914–18, prepared a confidential memorandum on the machinery for dealing with the recruitment of medical practitioners in case of war, and set up Emergency Committees for England and Wales, Scotland, and Northern Ireland. These committees were kept in being and became active in November, 1936, when the clouds were beginning to gather over Europe. The committee for England and Wales was then reconstituted on a wider basis. Its first task was to circularize all members of the profession in order to ascertain what service at home or abroad each would be ready to give on the outbreak of war and before compulsory service might be imposed. Local medical emergency committees for each Division were established, and local emergency officers were appointed whose first function was to ensure completion and return of the questionary. In this way a register of the profession was compiled and maintained at headquarters, with copies of its local parts in the possession of each divisional emergency officer. By the spring of 1938 information was available as to 75% of the profession in Great Britain and Northern Ireland, according to their ages and types of practice. After the Munich crisis in the autumn of that year the percentage rapidly rose to 95, and it reached 98 in the early days of the war. This register, constantly revised, has been the foundation of the work of the committee.

The crisis of 1938 exposed some defects in the organization for effective mobilization of the profession. The information at the disposal of the committee was found to be insufficient to enable it to bring the medical services quickly into action in appropriate directions. In particular Government Departments and local authorities, who were the local agents for civil defence, appeared to have different ideas as to the medical staffing of their units, including first-aid posts; no definite understanding had been reached with the hospitals; further, there was no central or local information as to which areas had been assigned for the reception of evacuees. It was evident that the central and local committees could not successfully fulfil their task until their position as agents of the Government for the allocation of medical man-power was more clearly defined. Representations were accordingly made to the Government urging it to bring all medical services for civilians under one control, to co-ordinate them with the medical departments of the fighting Services, and give the emergency committees authority, in consultation with the Government organization, to allocate medical personnel to the various services in time of emergency. These views were largely accepted, and the wider responsibilities of the committees called for their further reconstitution. The Central Emergency Committee was greatly enlarged so as to include every important branch of medicine and remove any suspicion that its representatives were exclusively members of the British Medical Association. It became, in effect, an independent medical body responsible to the Government, although that part of its cost which was not refunded by the Government continued to be borne by the Association. Local emergency committees were made similarly elective by the whole profession in each Division.

When war broke out in September, 1939, the emergency committees became the Central and Local Medical War Committees, and their status had been fully recognized. The Emergency Medical Service and the schemes for civil defence and evacuation were well advanced. The immediate requirements of the fighting Services and the names of those with Service commitments were known. The central and local committees had been in active collaboration with the authorities in making the arrangements, and each member of the profession knew what calls would be made upon him. It was convenient also for the local committees to undertake for the Association and in collaboration with local insurance committees the administration of the Protection of Practices Scheme. A close working relation, by cross-representation and a common secretariat, had been attained with a Committee of Reference established by the Royal Colleges at the request of the Government for the placement of men of specialist or near-specialist rank in hospitals within the area of London County. Under these conditions the mobilization of medical personnel was achieved with the minimum of disorganization.

The burden borne by the medical war committees has been heavy. In the first year of the war, indeed, the staff of the British Medical Association could scarcely have carried it but for the temporary suspension of most of the Council and nearly all the normal committee activities. Inevitably changes of method had to be made in the light of experience. The anticipated casualties from air raids did not happen, and the Central Medical War Committee, in conjunction with the Committee of Reference, had to draw the Government's attention to the disbalance which the originally approved hospital scheme was causing among specialists, especially in London, where whole-time service had been extensively adopted. The system was then modified and guided from time to time by an Advisory

Emergency Medical Service Committee of the main committee, with direct access to the Minister of Health. This committee has been continuously watchful of the terms and conditions of service of consultants and specialists.

The bulk of the work of the Central Medical War Committee has, however, fallen upon its Services Committee and, for a time, upon the Young Practitioners Subcommittee, which dealt directly with the recruitment of recently qualified men and women without local attachment. With the institution of compulsory service the Services Committee became the central tribunal for the medical services. It has functioned in close association with Local Medical War Committees, Government Departments, the fighting Services, and all manner of bodies employing medical officers in such a way as to hold the unsteady balance between their several needs. Their demands have not always appeared to be synonymous with their needs, and it has been this committee's delicate task to sift the claims of bodies and individuals and arrive at a conclusion as to whether civil needs were such as to render recruitment or direction inadvisable. But, while it has been able to manipulate the pool of civilian doctors, usually with the help of local committees, occasionally against their representations, it has not been in the position to influence directly the demands of the fighting Services, although the presence on the committee of the representatives of these Services may have brought home to them from time to time the distressing state of civilian practice. In 1940 the unabated calls of the Services caused such concern that the Government was asked to look into them, and accordingly a special Government committee was set up, consisting of civilian and Service members under the chairmanship of Sir Arthur Robinson. This committee sat almost continuously for a fortnight, and, while its findings were not disclosed, one of the results was the establishment of the Medical Personnel (Priority) Committee under the chairmanship of Sir Geoffrey Shakespeare, M.P., which met the request of the Central Medical War Committee for a permanent wartime committee to scrutinize Service as well as other demands for medical officers and determine specifically the number to be recruited from time to time.

The volume of work of the Services Committee has not diminished. The multifarious matters coming before it and the local committees are infinite in their variety and complexity. Toward the end of the European war fewer medical officers have been recruited, but civilian needs have had to be met by a profession weakened by the attrition of age, retirement, ill-health, and death. In spite of repeated appeals the public have been unable to limit their calls on practitioners to a level within the capacity of the depleted profession. Each case of recruitment has therefore become an increasingly difficult problem. The requests, too, for the release of practitioners from the Services because of local or other special predicaments have grown in number, and the study of each of these and of its repercussions has been difficult and time-consuming. More recently the Central Medical War Committee has been engrossed in the problems of demobilization, as the letter to practitioners on service recently published in the *Journal*[1] has indicated. It may be noted that this question of demobilization was before the Central Emergency Committee at its meeting of October 1, 1937, and has been kept constantly in mind ever since.

Those who have experience of the conduct of committee business and who have seen the Central and Local Medical War Committees at work must have been struck with the care the members have devoted to the consideration of the mass of detail presented to them, with the efficiency of their action, and with the courtesy they have extended to those who have come before them. It will be some reward for their labours and a comfort in carrying out their unfinished tasks to know how much their work has been appreciated by the Minister to whom they have been responsible.

---

[1] *Supplement* to the *British Medical Journal*, May 26, 1945, p. 95.

VITAMIN C AND THE GUMS

The swollen, soft, spongy, and haemorrhagic gums of scurvy respond rapidly to treatment with vitamin C, but there is much doubt about the part played by vitamin-C deficiency in the aetiology of inflammatory conditions of the gums seen in general medical and dental practice. A careful clinical examination should always be made of a patient with swollen and bleeding gums before vitamin-C deficiency is diagnosed, as the gum lesion may be a manifestation of a haemorrhagic condition. It is recorded that four cases of uraemic toxaemia with bleeding gums were once diagnosed as cases of vitamin-C deficiency.[1] Kruse[2] states that the macro- and micro-scopical examination of the gums affords a simple and objective method of detecting vitamin-C deficiency. The sites affected are stated to be involved in a definite order: interdental papillae, the marginal gingivae, and then the alveolar gingivae. Kruse describes vascular engorgement as the first stage, followed by swelling of the gums around the neck of the teeth. If the condition is untreated it becomes chronic, when the swelling is masked by oedema, which causes the gums to look pale. Finally, atrophy of the gums occurs, the dental papillae recede, and the teeth become loose. According to Kruse, these changes are reversed by vitamin C, but his observations conflict with those of Crandon[3] and of Farmer.[4] After six months on a scorbutic diet Crandon failed to observe any pathological changes in his gums, although the vitamin C in the white cell layer was zero. This was confirmed by Farmer and his colleagues, who kept volunteers on a scorbutic diet for many months but failed to observe any pathological changes in the gums, teeth, or bones of the jaw as seen with the naked eye, or by means of the biomicroscope and *x* rays: as in Crandon's case, the level of vitamin C in the white cell layer was zero.

In spite of these careful observations many workers have claimed that gingivitis alone is indicative of vitamin-C deficiency, and there are several reports on the beneficial effects of prescribing fruit juices or synthetic vitamin C. Vitamin-C deficiency, as evidenced by low excretion values or plasma levels, has also been recorded in patients with such conditions. Much of this work was uncontrolled, and as local treatment was also often carried out the effect of the vitamin C was difficult to assess. As pointed out previously in these columns,[5] urine tests and estimations of vitamin C in the plasma are of doubtful value for the detection of vitamin-C deficiency. More recently a number of workers have failed to find any significant relation between the intake of vitamin C and the incidence of gingivitis. Burrill,[6] from observations on 1,400 patients, noted that, although a large number of subjects with low vitamin-C levels in the plasma had gingivitis or periodontal disease, the correlation was not close enough to suggest any causal relation. He believes that a patient likely to neglect his mouth will also neglect his teeth; in other words, vitamin deficiency and periodontal disease may have the same origin, although they are not related aetiologically. MacDonald[7] noted a high incidence of bleeding gums and gingivitis among British naval ratings, but he was unable to show that it was related to vitamin-C deficiency, and the condition cleared up with local treatment. Similar observations were made by Ungley and Horton.[8] Local conditions, such as infection and tartar, were sufficient to account for the unhealthy gums which did not respond to treatment with vitamin C. In a carefully controlled study of nearly 3,000 R.A.F. personnel Stamm, Macrae, and Yudkin[9] found that 20% of them suffered from bleeding gums; vitamin C and the inert control tablets were equally ineffective in treatment.

[1] Wright, F. J., *East Afr. med. J.*, 1944, **21**, 146.
[2] *Milbank mem. Fund Quart.*, 1942, **20**, 290.
[3] *J. Amer. med. Ass.*, 1941, **116**, 663; and *New Engl. J. Med.*, 1940, **222**, 748: 1940, **223**, 353.
[4] *Federation Proc.*, 1944, **3**, 179.

A high incidence of vitamin-C deficiency has been reported in subjects in the British Army and Navy suffering from ulcerative gingivitis[10] (ulcerative gingivo-stomatitis, Vincent's disease, "trench mouth"). But it is doubtful if it is directly related to vitamin-C deficiency, as it responds to local treatment alone, although some workers claim to have obtained the best results by local treatment combined with vitamin-C therapy. Pincus[11] and Williams[12] found no evidence of vitamin-C deficiency in a number of subjects suffering from ulcerative gingivitis, and vitamin C appeared to have no curative action. The chief factor in the spread of ulcerative gingivitis is probably contagion, due, for example, to dirty oral habits, unclean crockery, and a particular variety of kissing. It is conceivable that vitamin-C deficiency may result in lowered resistance of the gums to infection—although this is difficult to prove, and is certainly not borne out by the work of Crandon and of Farmer—but once the patient has ulcerative gingivitis large doses of vitamin C are ineffective in curing it.

These conflicting views on vitamin C and gingivitis are undoubtedly due to confusion over the aetiology and symptomatology of inflammatory conditions of the gums, the absence of established standards for the normal, and the lack of controlled observations by earlier workers. It is quite likely that there are three clinical entities: (1) scorbutic gingivitis, which must be relatively rare in this country, usually appears after other scorbutic symptoms, and responds to vitamin C; (2) ulcerative gingivitis, or Vincent's disease, which is primarily infective, is not related to vitamin-C deficiency, and is not cured by vitamin C; and (3) non-specific gingivitis, characterized by swollen, bleeding gums, which is common in the population at large and is unaffected by vitamin-C therapy.

TOXICITY OF SALICYLATES

E. K. Marshall's teaching on the importance of maintaining a steady concentration of sulphonamides in the blood has not been without effect. Much of the recent work on mepacrine has been based on the idea that to suppress clinical malaria one must maintain a certain concentration in the plasma, and now Coburn[1] states that a concentration of sodium salicylate greater than 36 mg. per 100 c.cm. is necessary for the effective relief of the symptoms of acute rheumatic fever. To obtain this high concentration the dose must be between 10 and 20 grammes per day—that is, from 150 to 300 grains. The usual dosage in this country is 8 grammes, or 120 grains, a day. Very high doses have resulted in toxic effects which were previously unknown. The most striking is a fall in the amount of prothrombin in the blood. Thus in a case reported by Fashena and Walker[2] the bleeding time was 5 min. 30 sec., the clotting time 10 min., and the prothrombin time 2 min. 45 sec.—"a value more than five times the normal, which connotes almost complete absence of circulating prothrombin." That the fall in prothrombin was due to salicylates has been proved by Link and his colleagues,[3] and also by Rapoport and Guest,[4] who observed it when they gave salicylates to rats and rabbits. In this connexion we may recall the late Sir Arthur Hurst's observation of the frequency of haematemesis in patients with gastric ulcer if they were given aspirin (acetylsalicylic acid). There can then be no doubt that salicylates will reduce the patient's prothrombin and decrease the power of his blood to clot. Does this matter? Is diminished coagulability of importance clinically? Apparently it may be. Ashworth and McKemie[5] have recently observed two deaths from haemorrhagic encephalitis in which salicylates appeared to be the lethal factor. The danger from diminished prothrombin can fortunately be removed by the simple expedient of giving the patient vitamin K or a related substance such as menaphthone (*B.P.*). Shapiro[6] has estimated that 1 mg. synthetic vitamin K will counteract the effect of 1 gramme (15 grains) of acetylsalicylic acid. No doubt the regular use of menaphthone together with salicylates will gradually become established.

There are other effects of salicylates, which Sable[7] considers in a recent review. Sometimes there is severe hyperpnoea, which is thought to be due to stimulation of the respiratory centre; the respiration has been found to increase from 5 to 37 litres per minute. This can be treated only by withdrawing salicylates, when the hyperpnoea subsides in 48 hours. Salicylates like aspirin may lead to an allergic condition in which there are asthma or dyspnoea, urticarial wheals, and subcutaneous oedema. These clear up when adrenaline is injected. The best-known symptoms of toxicity are nausea, vomiting, tinnitus, and partial deafness. These have been widely studied in the past, and have furnished those who teach pharmacology with a striking example of the variation which exists among patients in their sensitivity to drugs. As long ago as 1913

Hanzlik showed that in some men toxic effects occur after as small a dose as 40 grains of sodium salicylate, whereas others could take as much as 460 grains. Usually symptoms appeared after a dose of 190 grains.

GOING HOME

All over Europe the war-exiled are making for home, hungry for the familiar setting from which they were uprooted. For many there will be great happiness in reunion; for others the bitterness of loss, human and material; for all there must be in some degree the Rip van Winkle shock of realizing that neither for themselves nor for their families has Time stood still, so that the days of long ago can never be repeated. In its wisdom the Ministry of Health has recognized that a domestic problem of this kind arises with regard to the evacuated children now returning to their homes. A circular addressed to county and county borough councils and welfare authorities in the Metropolitan evacuation and other "return home" areas describes the kind of rehabilitation difficulties likely to occur, and gives advice on how these can be ameliorated. It is a very human document, stressing such homely points as the mother's possible disappointment at finding that the "baby" she cosseted is now a self-reliant school-child, anxious to stand on his own feet—or the opposite problem of the ex-baby's jealousy of the younger brothers and sisters born during his absence. It is noted that the change from billet to home almost inevitably means a change of standards: some evacuees may have grown accustomed to better social conditions, others to less care and comforts; in either case the imagination of childhood may well result in stories of Princess- or Cinderella-like experience, disturbing to parents who have not visited enough to judge for themselves and so add the requisite grains of salt to these fantasies. Country habits, too, may be hard to abandon in town, where "picking flowers becomes stealing . . . going for a walk can easily turn into 'wandering,' and climbing trees into 'wilful damage'"; though the adaptability of children and the common sense of authorities probably make this problem less important than others. For those who have grown attached to their foster-parents the question of divided loyalties may be a troublous one, accentuated by the contrast between dream pictures of the perfect home, so naturally built up by wanderers, and the imperfect, because human, reality. There may be, for those who have been fortunate in evacuation experience, a revulsion of feeling towards home, and a desire to go back to the foster-home, which in its turn may be glorified by absence.

There are also the special problems of those children who have been in hostels or residential war nurseries. These have been living as members, not of a family, but of a community planned and run for their benefit, usually in groups of their own age. They have as a rule become accustomed to high standards of physical well-being, but inevitably their opportunities for acquiring independence and resource have been limited. Many of those who return from nurseries will have forgotten, while others have never known, what life in a family is like. They have missed the normal experience of mixing with older and younger children, and may also be unused to the common risks of a household, such as boiling kettles, unguarded fires, or to the dangers of road traffic. Perhaps more important still, they are unused to parents except as visitors laden with gifts and free to devote all their time to their offspring. To smooth over the transition period it is suggested that home visits shall be arranged immediately after the return of children by welfare and education authorities, that teachers should encourage parents to consult them, and that the aid of such children's organizations as Scouts, Guides, clubs, and play-centres should be invoked. For children showing signs of special disturbance reference to the school medical officer and to child-guidance clinics is advised. The potential value of health visitors' friendly advice to mothers is rightly stressed in relation to ensuring continuity of good routine and diet for the under-fives. To sum up, this circular seems a notable example of planning for health, mental and physical, and should do much to safeguard at home the children whom the Ministry has so long and carefully shepherded on their wanderings.

NARCOLEPSY AS NEUROSIS

The work of Adie, Brain, Kinnier Wilson, and others has shown that narcolepsy may occur as the result of a lesion of the hypothalamus, or as an idiopathic state. In the majority of cases no cause for the condition can be discovered. Since the syndrome was first described by Gelineau in 1880, the frequency with which it is diagnosed has increased very much, particularly in latter years. Up till now it has always been looked on as due to physical states, probable related in nature to the causes of idiopathic epilepsy. The suggestion has now been made by Langworthy and Betz[1] that it may occur as a neurotic syndrome. These authors describe in detail the psychiatric background in two cases of narcolepsy which they have personally observed. They also review in psychiatric terms the available history of four further cases which had been previously investigated along laboratory lines by Levin.[2] In their opinion the data indicate that the syndrome arose in these cases in a situation of conflict, and in men and women whose personalities were incapable of a healthy resolution of the conflict; the illness represented a flight from the situation and a solution along neurotic lines. They point out that hysterical or hypochondriacal patients may suffer from somatic symptoms, such as precordial pain and palpitation, and nausea, anorexia, and diarrhoea. Narcolepsy, in this view, would represent the utilization of the nervous system to provide a defensive reaction.

The evidence so far adduced seems rather flimsy. It is not enough to show that a situation of conflict arose and symptoms of narcolepsy developed at about the same time to prove that they are causally related. Neurotic symptoms in general are symptoms which in minor degree are the common experience of man; but which occur with unusual severity in persons of predisposed constitution or in circumstances of stress. The narcoleptic syndrome is unusually clear-cut and distinctive and shows no readily comparable analogue in the normal range of experience. It is certainly related to dysfunction of the hypothalamus, and is specifically amenable to treatment by amphetamine sulphate. More evidence will be required than is here provided that the general run of idiopathic narcoleptics are suffering, as the authors suggest, from a neurosis.

THE HALF-YEARLY INDEXES

The half-yearly indexes to Vol. II of the *Journal* and the *Supplement* for 1944 have been printed. They will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Accountant, B.M.A. House, Tavistock Square, London, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

NOTES ON A MIXED SHORT-TERM DAY NURSERY

BY

J. F. DOW, M.D.

Medical Officer of Health for the County of Westmorland

The nursery which is here described is situated in a pleasant country-house on the shores of a beautiful lake. It has a large garden, which supplies the house with vegetables; and poultry provide the nursery with fresh eggs. It was first established as a day nursery with a view to the reception of the children of women working at a large neighbouring war factory. However, the requisite number of children were not forthcoming, and in late 1943 it was amalgamated with a neighbouring nursery, which had been used solely for the reception of young children during the period when their mothers were having a further confinement. Under this new arrangement residence was provided for 21 children, and day children up to a similar number could be admitted; throughout the year the residential part of the nursery varied from 17 to, during rush periods of evacuation, 24. Day children numbered from 5 to 10.

Throughout 1944 the nursery was thus taking three different types of children: (1) There were 10 children attending daily who came into the nursery between 7.30 and 9 a.m. and left between 5 and 6 p.m. (2) There were 97 short-term children aged from 1 to 5 years who were admitted during the sickness or confinement of their mothers. These were to a large extent the children of mothers evacuated from dangerous areas. (3) There were 14 children whose mothers were employed on war work that, because of the hours or other circumstances, made it impossible for the children to be with them. It was expected, and has generally been fulfilled, that the mothers should visit these children at week-ends and keep in touch with them.

The nursery is divided into three groups: a day and night nursery for 0–1 year, for 1–3 years, and for 3–5 years. It is obvious that a nursery of this varied type presents considerably more problems than would arise from a complete day nursery or residential nursery. The constant admission of new children for only a short time creates a greater risk of infection being brought in; they enter unclean and untrained, and these difficulties are corrected only when it is time for them to leave.

The staff consists of: (1) The matron, who is a fully trained State-registered nurse. She has a position of considerable responsibility, as children are sometimes admitted at only a few hours' notice, and one must rely on her examination of the new arrival to exclude infection. Moreover, the whole character of the nursery depends entirely on her—whether the atmosphere is that of an institution or a home. (2) Two child-care reserves; two nursery assistants; and three probationers. At first sight this staff will seem excessive, but when one considers the length of the day's programme (detailed below) and also that every member is entitled to three hours off duty each day, a day off each week, and three weeks' holiday each year, I think it will be agreed that such a staff is necessary. Indeed, quite apart from the care of the children during the day, all the children's clothes and napkins, etc., are washed by the nursery staff, and only the heavy linen is sent to the laundry. The mending, marking, and ironing of all the clothes are done by the staff, largely in the evening.

The daily programme for the children is as follows:

6 a.m.—Children under 1 given milk.

6.45 a.m.—All children wakened; toilet; orange juice; wash.

7.15 a.m.—Breakfast: Porridge or corn flakes; prunes, bacon, fried bread, or fresh eggs, scrambled or poached; bread-and-butter, jam or syrup, rusks, milk.

8 to 8.30 a.m.—Toilet; wash; free play.

9.30 to 10 a.m.—Cocoa or milk and biscuits; cod-liver oil and malt.

10 a.m. to 12 noon.—Out for walk or play in the grounds, and sleep in the prams or in the night nursery; toilet.

12 noon.—Lunch: Soup or mince or fish, or cheese dish, potato and gravy, and two vegetables when possible; rice or semolina, custard and fruit (own produce bottled or fresh in season) or prunes; sponge puddings; orange juice.

12.45 to 2.30 p.m.—Toilet; wash; rest period.

2.30 to 4 p.m.—Toilet; either walk or play, or drawing; plasticine; imaginative play; nursery rhyme songs to piano. Older children love to gather leaves, twigs, and flowers for nursery.

4 p.m.—Tea: Dates and grated carrot, or shredded cabbage; fresh scrambled eggs; home-made cakes, or junket, bread-and-butter, rusks or biscuits.

4 to 5.30 p.m.—Toilet; bathing and bed. Preparation of daily children for home.

9.30 to 10 p.m.—Baby-feeding and toilet.

Diet and rest for the 3–5 year children are the same as for the 1–3 year group. The older group has more constructive play, including chute, sand-pit, and swings; and songs and dances to the piano; also, their walks are taken in the surrounding woods and field, and to a near-by farmyard. Their bedtime is 6.15 p.m., after bathing.

Infectious Diseases

During the year all the children had chicken-pox, and many had rubella; in both instances the infection was traced to a day child. Three of the young staff were also affected by the latter disease. One child was admitted and discovered to be in an advanced stage of whooping-cough, but all the children were at once immunized and there was no further case. Every one of them has, of course, been immunized for diphtheria. These infections were of a mild type, and gave rise to no complications. During the whole year there was no other case of sickness necessitating the children being kept in bed, and the general standard of health was excellent. During the first few days of admission a child is fretful, and generally needs up to 48 hours to settle down; this also is a period of extra work for the staff, and may account for the fact that the short-term residents do not gain weight in proportion to the permanent ones.

The day children vary in age from 2 to 5 and also in the length of time they attend. They all gained weight, to an average of 5 lb. 8 oz. The 97 short-term resident children aged 1 to 5 years were admitted for a period of two to seven weeks, and gained weight as follows: 1–2 years, 12 oz.; 2–5 years, 1 lb. 14 oz. The 14 permanent residents who were in the whole year gained weight as follows: 0–1 year, 16 lb. 4 oz.; 1–2 years, 7 lb. 9 oz.; 2–3 years, 6 lb. 14 oz.; 3–5 years, 7 lb. 8 oz.

Conclusions

P 35702

The nursery has really been fortunate in avoiding the more serious types of infectious diseases, and was even unaffected by the influenza epidemic. This result may be in some way due to the fresh-air policy, but it must be admitted that the risk of such infection is very great. As a short-term nursery for children of mothers who were being confined in our maternity home or had been taken suddenly ill, it has been exceedingly useful. It has been invaluable in dealing with the children of the group of London expectant mothers who were evacuated to this district in the summer.

The improvement in weight, health, and general condition of the whole-time resident children is most gratifying. One satisfaction has been that nearly all the mothers have kept in touch with their children and helped so far as was possible. It is of course open to argument whether mothers of children of these ages should work; personally, I am not convinced that children under 2 years of age should be away from the mother. However, there are certain reasons during wartime, and in the cases of illegitimacy, where this course seems essential.

Finally, I would stress that the success of a nursery depends to a very great extent on the matron. She must be given responsibility and be trusted to run her nursery without undue interference; her success will depend as much on her motherliness as on her nursing skill. Our matron was the widow of an R.A.F. casualty, and had her two children in the nursery. These children received the same care and attention as all the others, and no more.

C. L. Steinberg (*U.S. nav. med. Bull.*, **42,** 567) in the course of five months has seen 10 cases of meningo-encephalitis in a total of 165 cases of mumps. As mumps meningitis is rarely fatal pathological reports on the condition are few, but Larkin and Gordon found congestion of the pia mater with patchy infiltration of the parenchyma along cerebral vessels.

WORK OF THE CENTRAL MEDICAL WAR COMMITTEE

MINISTER OF HEALTH'S TRIBUTE

The following letter has been addressed by the Minister of Health, Mr. Henry Willink, to Dr. Charles Hill, Secretary of the Central Medical War Committee.

My dear Dr. Hill,

Now that the war in Europe has ended I feel I must convey to the Central Medical War Committee my warm thanks for their valuable help and co-operation during the last six years. The task which the Committee readily undertook at the outbreak of war assumed a magnitude and complexity greater than could have been foreseen, but they have faced its problems and shouldered the great volume of work with a determination and efficiency which is very highly appreciated.

Their first duty was to provide the practitioners necessary for the medical needs of the Armed Forces and I well know how successfully this was achieved. It was, indeed, a positive contribution to victory. I know, too, what difficulties were entailed in meeting the demands of the Services—how the Committee had, throughout, to weigh the counter-claims of civilian needs in general practice, hospitals, public services, teaching, research and other fields. As the war lengthened and civilian medical resources were progressively depleted it could almost be said that each individual case became a problem, but the Committee could always be relied upon for a sound and fair-minded judgment in striking the balance between civil and military needs.

This was the Committee's main task. But they have also devoted much careful consideration to safeguarding the interests of serving practitioners and have had before them the claims of civilian services overseas, relief and missionary work, problems affecting aliens and a wide range of other matters. The same care has been evident in the Committe's handling of all of them.

The success of their work in meeting the demands of the Services has inevitably placed a heavy strain upon general practitioners, hospital staffs and others remaining in civilian life. Many of them have carried on under conditions of great difficulty and almost intolerable strain. I cannot allow this opportunity to pass without expressing the Government's thanks to all those practitioners, for the manner in which their burdens have been borne.

The Committee's work is not yet finished and what remains will present many new problems, but I am confident that they will meet the calls upon them with the same success as has attended their efforts in the past.

I would also ask you in your capacity as Liaison Officer to convey to members of the Committee of Reference my sincere thanks for the valuable work they have done within their special field of reviewing the hospital staffs of Greater London.

Finally I should be glad if you would let members and secretaries of Local Medical War Committees know how deeply I appreciate their contribution to this work, to which they have given voluntarily and without stint so much of their time and energies throughout the years of war.

Yours sincerely,

Ministry of Health,
Whitehall, S.W.1.
June 25, 1945.

HENRY WILLINK.

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held on May 23, with Dr. R. A. Young, president, in the chair. The report and accounts for 1944 were presented and approved. £5,125 was distributed in grants among the 55 widows who were in receipt of relief during the year. The total membership of the Society was 287 at the end of 1944. One widow had received £1,925 on behalf of herself and her son. Mr. W. Gilliatt was elected a vice-president, and Dr. R. R. Trail and Mr. G. T. Mullally directors. A legacy of £5,000 was received from the executors of the late Dr. Charles Reid, of Stafford. A vote of thanks was passed to the editors of the medical journals who, from time to time, publish reports of meetings of the Society. Relief is granted to the widows of deceased members whose yearly income is £135 or less. Membership is open to any registered medical man who, at the time of his election, is residing within a twenty-mile radius of Charing Cross. Full particulars may be obtained from the secretary, 11, Chandos Street, Cavendish Square, London, W.1.

CENTENARY OF ST. MARY'S HOSPITAL

The centenary of St. Mary's Hospital, Paddington, was celebrated by a Mansion House dinner on June 27, when an appeal was launched for reconstruction and extension. The scheme provides for rebuilding of the present hospital, with an increase of bed accommodation from 414 to 700, a new west block to house the out-patient and casualty departments, the fracture clinic, and the diagnostic *x*-ray department, with about 50 additional beds, and on the east side, beyond the medical school, the completion of the nurses' home, a portion of which is already built.

The Lord Mayor presided at the dinner, saying what pleasure it gave him to offer civic hospitality to a great teaching hospital which, like the other teaching hospitals, would play a large part in any future national health service scheme. Three great contemporary names were associated with St. Mary's—Sir Almroth Wright, the pioneer of vaccinotherapy, Sir Alexander Fleming, the discoverer of penicillin, and Lord Moran, in whose charge had been the health of the Prime Minister during the war years.

Mr. Brendan Bracken, First Lord of the Admiralty, said that the hospital was in the constituency which he was at the moment contesting, and it was a great refreshment to escape from the hustings to praise St. Mary's. Many institutions after a hundred years began to show distressing signs of old age, but St. Mary's remained one of the youngest of the great hospitals, alike in its work in the spheres of healing, of teaching, and of research. It was a nursery of doctors and a centre of vigorous and far-reaching investigation of medical problems. He added that whatever form the Government plan for a national health service ultimately took it would mean an even greater call on the medical profession, and so the responsibility for establishing the future health of the country rested to a great degree upon the voluntary teaching hospitals.

Lord Moran, P.R.C.P., Dean of St. Mary's Medical School, whose name was coupled with the toast of the hospital, read the following message from the Prime Minister:

> "In the future health services of this country greatly increased demands will inevitably be made on St. Mary's as one of the vital medical teaching centres in this country. No hospital has a finer record of work and achievement. The discovery of penicillin by Sir Alexander Fleming has placed the whole world in its debt. It is clear from its past record that there exists in this institution an organization of exceptional worth in the field of medical education, treatment, and research. Let us, therefore, be quite sure that its work is in no way hampered by lack of proper accommodation and modern equipment. I commend most heartily this appeal to all men of good will throughout this country, our Dominions, and also to our very great friends in the United States of America. No cause could be more worthy."

Lord Moran mentioned that between the landing in Normandy and the end of the European war thousands of men had been treated with penicillin, and 95% of those so treated had recovered.

Mr. Anthony de Rothschild, chairman of the board of management of the hospital, mentioned with pride the fact that his family had been connected with St. Mary's for roughly half the century which had been completed. In a reference to some of the benefactions to the hospital he announced that King Edward's Fund for London had made a preliminary gift of £10,000. Lord McGowan, treasurer of the Inoculation Department, read a message from Field-Marshal Sir Bernard Montgomery, who, it was hoped, would have been present. The message referred to the widespread admiration aroused by the work of the Inoculation Department, and added that penicillin had revolutionized the treatment of the wounded in the field and had saved countless lives.

A collection taken at the Mansion House tables during the dinner resulted in £145,000 for the appeal fund. The centenary celebrations were continued during the week at the hospital, which was visited by the Queen, who is its president. The deeds of the land presented by the Great Western Railway for the extension of the site were handed to Her Majesty. Demonstrations of the scientific work of the hospital have also been given.

Reports of Societies

BONE AND SOFT-TISSUE DEFICIENCY IN THE LIMBS

Among the chief subjects discussed at the spring meeting of the British Orthopaedic Association, which was held at Horton Hospital, Epsom, and at Hill End Hospital, St. Albans, under the presidency of Mr. St. J. D. **Buxton**, were bone and soft-tissue deficiency in the limbs, penicillin, and vascular lesions.

Cancellous Bone Grafts

Wing-Commander I. **Lawson Dick** opened a paper on the use of cancellous bone transplants with a historical survey of our knowledge of osteogenesis in relation to bone grafting from the time of John Belchier in 1736. The generally accepted view now was that the viability and osteogenetic properties of transplanted bone depended upon the facility with which it could be revascularized. Osteogenesis and viability were long delayed in the depths of massive cortical grafts and most readily ensured in cancellous bone. If the mechanical stability of cortical grafts could be maintained by other means healing and consolidation would be hastened by the superior osteogenetic properties of cancellous bone. A disadvantage of removing grafts from the tibia was the not uncommon occurrence of fatigue fractures in the donor bone. The most rapid and sure method of bone transplantation was by the use of cancellous chips from the ilium.

Mr. S. L. **Higgs** described 71 cases of bone grafting, 60 being for non-union of the long bones; in 20, cortical grafts alone were used, and in 40, cortical grafts plus cancellous chips. All had resulted in bony union, but union had taken at least twice as long with cortical grafts alone as it had with both types of graft, except in the femur, where the average had been half as long again for healing with cortical grafts alone. Rigid fixation must be applied in the operative procedure if cancellous chips were to do their work well and quickly. To maintain this with length and alignment was the reason for combining a cortical graft with the chips. Referring to the methods used for different long bones the speaker emphasized that there need be no hesitation in excising all sclerosed bone from the site of non-union: similarly all fibrous tissue to facilitate vascularization. Associated skin defects must be adequately treated by plastic methods beforehand.

Mr. Ivor **Robertson** discussed the treatment of chronic infective osteitis, the essentials of which must be a careful but extensive excision of all infected bone and scar tissue and the replacement of tissue loss by bone, muscle flaps, and full-thickness skin grafts. Such treatment required careful selection, and those described had been cases of chronic haematogenous osteitis of limited area and surgically accessible and cases of chronic osteitis resulting from compound fractures or war wounds. The treatment was carried out in three stages under penicillin control: first, by excision of the bone and soft-tissue defects and then covering with Thiersch grafts; secondly, a month later, by closure after removing this graft and substituting a full-thickness skin graft; thirdly, at least two months later, by bone grafting. Where an ununited fracture was present both cortical and cancellous chip were involved. In cases of chronic haematogenous osteitis stages 2 and 3 might be combined, and iliac cancellous chips alone were packed into the dead space between the walls of the cavity and skin flap. To ensure an adequate blood supply a muscle flap was swung over them and sutured to the periosteum.

Mr. Rainsford **Mowlem**, discussing in more detail the problem of soft-tissue defects in the limbs, emphasized the need for continuous care from the beginning of all elements of damage—skeletal, vascular, neuromuscular, and skin covering—in all injuries. No one element must be ignored, but from every point of view a limb otherwise intact was useless without its skin covering. Indeed fibrosis secondary to infection and exposure—the influence of this upon underlying muscles and joints—would prevent adequate treatment for these deeper parts and greatly increase the disorganization of the limb as a whole. The use of free grafts and pedicles or flaps was discussed. In the former, split grafts could be applied at any time during which there was a good vascular surface, and generally as soon as possible. For adhesion, maintained pressure was preferable to any glues. If the bed was avascular it must be excised. The presence of infection was no contraindication to grafting so long as it was dealt with by suitable chemotherapy. Pyocyaneus, proteus, or *B. coli* infection was a special problem, but even here successful grafting was not impossible. Exudation was the difficulty, and its mechanical effects could be minimized by using strip or postage-stamp-shaped grafts. After a month all grafts tended to become dry and to contract; massage with grease would help. Grafted areas below the knee needed prolonged pressure bandaging to reduce the ill effects of oedema. In weight-bearing surfaces keratosis might be aided by the use of the sulphydryl radicle. Usually here, however, split grafts should only be a preliminary to whole-thickness grafts. The design, formation, and methods of transplanting whole-thickness grafts were discussed, particularly the possibilities, where indicated, of flap grafts in the primary treatment of certain types of injury, noticeably in the hand.

Penicillin Treatment

Prof. L. P. **Garrod** said that, whereas the results of penicillin therapy in soft-tissue lesions could be almost guaranteed, the story was very different in bone lesions. In the future more liberal and purer supplies of penicillin should be available. With greater purification three types of drug were being isolated, the use of which might be found to be specialized according to the type of infection. Improved methods of parenteral administration now gave greater comfort to the patient and greater convenience to the staff. One of the difficulties was the rapid dissipation of the drug's effect, and this problem was being investigated by U.S. workers with the development of suspensions in oil and so forth, which were more slowly absorbed. It was hoped that manufacturing methods would eventually permit oral administration, the need, of course, being to protect the drug from the gastric acidity. British economy had called for much greater exploitation of local administration of penicillin, and there was much to be said for the good effects when thus used; adequate concentration could be achieved where most needed. Economy in the use of the drug had resulted in the discovery that the effect of penicillin, unlike that of other antiseptics, did not depend on its concentration. Its full action was obtained in low strengths; nothing was gained by increasing it, and, in fact, with some penicillin the reverse effect occurred. Prof. Garrod said the use of penicillin with sulphonamides was still being discussed, but his own work, though not conclusive, suggested that the sulphonamides interfered with the effect of penicillin on rapidly multiplying organisms.

Dr. G. F. **Kalmykov** (U.S.S.R.), in a paper on end-bearing amputation stumps in the lower extremity, said that an important field of surgery after the war would be concerned with re-amputation, because of the practice of emergency primary amputation behind the battlefield leaving definitive amputation to a later date. The extent of this varied in different nations. In Soviet Russia the percentage of re-amputations required was not less than 80. At one large centre in the U.S.A. he had found the percentage to be 78, while in British hospitals it did not exceed 25, which was explained by the more frequent flap amputation instead of the guillotine. Soviet surgeons where possible sought to create end-bearing stumps by an osteoplastic operation. Thus they followed the work of Pirogoff, whose well-known operation in the lower leg was being performed in Russia to-day. Other methods practised were those of Bier in amputations below the knee and Gritti Stokes in amputations above the knee. After such operations it was very important to prepare the stump properly for end-bearing: the latter achieved better distribution of weight within the prosthesis and resulting improved gait and confidence.

Dr. M. N. **Polonsky** (U.S.S.R.) described a new type of prosthesis in amputations through or near the hip-joint, which, he thought, solved the well-known difficulties of limb-fitting in this region. The advantages claimed were the relative lightness, greater comfort in walking and sitting; and greater economy in manufacturing costs and time. A normal type of above-knee prosthesis was employed, fixed to the usual type of pelvic band from the front of which a broad leather sling passed continuously downwards into the front of the prosthesis, over a transversely placed wooden roller, and out through the back of the limb to be attached to the back of the pelvic band, where its tension could be adjusted by lacing. The top of the appliance held a slightly hollowed, springy platform with soft felt lining upon which the soft parts of the hip gained a shock-absorbing support in walking.

Intervertebral Disk Lesions

Dr. E. J. CRISP, dealing with the early diagnosis and treatment of intervertebral disk lesions, said that the lumbar disks suffered trauma more often than was generally appreciated, but in the absence of crural pain or radiographic changes the resulting lesion was apt to be mistaken for sacro-iliac strain or fibrositis. The condition might be easily recognized by the extreme and persistent lumbar spasm at first associated with an increase in the lumbar concavity; later, scoliosis to the side of the lesion and lumbar kyphosis developed with sciatic pain, the lordosis occurring when rupture of the annular fibrosis was incomplete, and kyphosis when it was complete. Treatment was advised by conservative means along well-recognized lines such as the use of the plaster jacket. The essence of Dr. Crisp's views was that persistent lumbar spasm and a "tight" lumbar spine in an otherwise healthy patient indicated trauma to a disk and should be dealt with before the onset of sciatica.

Mr. J. E. O'CONNELL based his observations on the diagnosis of lumbar intervertebral disk protrusions on a study of 240 patients operated upon; 227 of these explorations had given positive evidence of intraspinal protrusions. By careful analysis of the clinical pictures one could locate with accuracy the site of intraspinal nerve-root stretching which affected the extradural portion of the nerve root leaving the spinal canal at the intervertebral foramen next below the disk level affected. In his series 39 cases had been studied before operation by myelography with 6 negative (15%) explorations. In 201 cases explored without myelography there had been only 7 negative operations (3.5%). While a variety of conditions could occasionally produce a picture similar to that of a lumbar disk protrusion, there were only three which did so at all frequently: an intraspinal tumour, a metastatic tumour in the lumbar vertebrae, and spondylolisthesis. Clinical examination would help in the differentiation, but certain accessory methods might be necessary. The speaker emphasized the need for adequate excision of the disk at operation. With proper selection the results in the majority of cases were excellent. Backache might prove to be frequent but rarely incapacitating. There had been a few recurrences, most often in the opposite leg.

Miscellaneous

Prof. J. PATERSON ROSS, in a paper on ischaemic phenomena following vascular injuries in the lower extremity, drew attention to the relation of the origin of the sural arteries, supplying the gastrocnemius muscles, to a region of special vulnerability in the popliteal artery. If these and all the terminal branches of that artery were blocked the leg was liable to be useless and sympathectomy would not improve it; pain might necessitate amputation. Where the sural arteries had been blocked but the collateral circulation preserved pain in the upper calf was troublesome after walking 300 yards; this was relieved by sympathectomy. If the popliteal artery had been damaged below the sural vessels pain was felt only in the lower calf and was not appreciably affected by sympathectomy. Block high up in the popliteal or femoral artery gave a good leg, which could often be improved by sympathectomy because the vessels to the calf—even if small—were still open. The popliteal artery was vulnerable to direct injury from bone and was liable to "spontaneous" thrombosis, which might be related to less direct trauma and to thrombosis the result of degenerative changes. In none of the cases described did gangrene occur, but in cases in which the popliteal or femoral vein had to be tied venous congestion was troublesome and was worse after sympathectomy. In arteriovenous fistula, if the main artery was ligated a good collateral arterial circulation developed, but without coincident ligation of the vein excessive venous drainage rendered the circulation of the periphery precarious. In one case of external iliac artery ligation in which the arteriovenous fistula had not been recognized, and also in 2 cases of wounds of the femoral artery and in 2 wounds of the popliteal artery, immediate paralysis of the lateral popliteal nerve occurred, suggesting an important additional segmental supply from the popliteal artery. These recovered like a regenerating peripheral nerve. Major D. LLOYD GRIFFITHS, R.A.M.C., remarked on the large number of cases of vascular injury to the larger vessels which he had seen in two years at a number of centres. He attributed this to the great conservation (due to chemotherapy) of limbs which formerly would have been amputated. In the past, and even now, ligature of main arteries had too light-heartedly been carried out. He considered that a very large proportion of all of them, even at reputedly safe sites, had been followed by vicious effects in the periphery, such as intermittent claudication, incorrigible anaesthesia, and gangrene of the digits. He pleaded for greater practice of lateral suture of arterial wounds and avoidance of ligature.

Fracture of the medial epicondyle displaced into the elbow-joint was discussed by Mr. JAMES PATRICK, who said that radiological diagnosis might appear difficult owing to the patient's being unable to extend the elbow in order to get a good antero-posterior view. If the medial epicondyle could be seen in the lateral view through the joint line, it could be regarded on this view alone as being incarcerated in the joint. After reduction of the incarcerated fragment (and in all simple medial epicondyle fractures) the fragment lay above the level of the joint line and so ceased to be visible in the lateral view. Reduction in early cases could be done easily by anaesthetizing the patient, gently abducting the forearm on the humerus, and applying faradism to the flexor muscles. Cases missed for more than five or six weeks after injury should be treated conservatively. In such cases the epicondyle eventually developed a bony fusion to the ulna. Anterior transposition of the ulnar nerve was probably unnecessary.

In some observations on scoliosis in relation to thoracic disease Mr. C. PRICE THOMAS said that this type of scoliosis followed most commonly upon conditions involving the pleura—e.g., chronic empyema and imperfectly treated haemothorax. Pulmonary fibrosis and atelectasis also gave rise to the deformity, but these only did so when the mediastinum was fixed. The underlying cause was a concentric pull on the chest wall towards the lung root or increase in intrathoracic negative pressure, or both. There was a striking difference in the chest deformity from that found in primary scoliosis; the intercostal spaces were much more contracted, and the curvature of the rib angles was increased and the anterior part of the chest flattened on the concave side of the scoliosis. The impression gained also was that vertebral rotation was not so marked in thoracic scoliosis. Mr. Thomas illustrated the types of remedial exercises used to prevent the deformity, in treatment of the causal disease, and in after-care of thoracic operations. In some operations, however, because so much of the spinal stability depended upon muscles having rib attachments which were lost, some degree of scoliosis was inevitable, but even so it could be mitigated by remedial exercises.

Mr. A. D. LE VAY, in a paper on costo-clavicular compression of the brachial plexus, discussed the importance of this factor in explaining certain neurological and vascular disturbances in the upper extremity, based upon one personal case and reference to recent literature. The patient a year previously had been treated for symptoms of the "scalenus syndrome" type (without cervical rib) by tenotomy of the scalenus anterior, after which the symptoms were much aggravated. Mr. Le Vay then operated under local analgesia, and found that the subclavian artery and brachial plexus were very superficial and bound to the back of the clavicle by dense inflammatory fibrous tissue. The artery was small and transversely grooved as if just released from a clamp; by bracing the shoulders back these structures were firmly squeezed between the clavicle and rib; a portion of the latter was excised so that artery and plexus sank back against the pleura. This operation was quickly followed by practically complete recovery.

Dr. P. BAUWENS demonstrated a method of measuring the action potentials of normal and denervated muscles, using a special amplifier with the cathode-ray oscilloscope connected by terminals embedded in the muscles being tested. By attaching a shunt having a resistance exactly counterbalancing the amplifier, with a microammeter it was possible to switch over during the test, and then from the calibrations of the microammeter obtain quantitative readings which were of great value in addition to the qualitative impressions received from the sounds emitted from the amplifier. Dr. Bauwens also demonstrated another apparatus devised by him which, taking advantage of the slower chronaxia of denervated muscles, enabled responses to electrical stimulation to be obtained from these muscles without affecting normal muscle fibres. Mr. W. SAYLE CREER showed a cinematograph film of foot faults related to form and function which, by means of dissections and ingeniously contrived models, illustrated the anatomy and physiology of the foot, its pathology and treatment. A clinical demonstration was given at Horton E.M.S. Hospital by Mr. St. J. D. Buxton and members of the staff of that hospital; Dr. P. H. Jayes, of the Plastic Unit, East Grinstead; Dr. E. E. Harris, of the Heritage Craft Schools; Mr. B. H. Burns and Mr. R. H. Young, of Botley's Park; Mr. F. C. Durbin, St. Nicholas Hospital, Pyrford; and by Mr. G. N. Goulden, Guildford.

LOCAL HEALTH SERVICES IN THE U.S.A.

At a recent meeting of the Fever Group of the Society of Medical Officers of Health, Dr. M. MITMAN presiding, Lieut.-Col. HUGH R. LEAVELL, of U.N.R.R.A., read a paper on present trends in local health service in the United States. He said there was a movement to incorporate cities and the surrounding suburban and rural areas into a single administrative health unit. Health centres were increasing and provided all types of preventive (and in some cases also therapeutic) services. In spite of objections on the part of some medical officers of health there was a movement to combine all Government-supported health services under a single administrative head. Health education of the public was being approached on a much broader basis and more intelligently than ever before. The quality of public health service was also improved through extension of the merit system, more adequate compensation, more widespread full-time service, and a wider use of public health nurses, etc. A planning committee of the American Public Health Association, with Dr. Haven Emerson as chairman, had recommended that the local health units in the United States be set up in accordance with certain fundamental principles:

1. The entire area and population of the United States should be served by full-time local health units. (In 1942, 31% of the population had no full-time service.)

2. The local community should be responsible for providing basic public health services—namely, vital statistics, control of communicable disease, environmental sanitation, public health laboratory services, maternal and child health services, and public health education.

3. A minimum population of 50,000 should ordinarily be required to provide necessary financial support of a local health unit.

4. The district for which a local health unit is responsible should have a distance from the centre to the periphery of not over 25 to 40 miles.

5. Districts should be set up to include both rural and urban population where possible; and there should be a minimum of 3 general hospital beds per 1,000 population, and a physician-patient ratio of not less than 1 to 1,500.

6. The minimum personnel for a local health unit should be: medical officer; 1 public health nurse per 5,000 population (with at least one of supervisory grade); 2 sanitation officers per 50,000 population (with at least one of professional grade); and 1 clerk per 15,000 population.

7. The local health unit should be suitably housed so that its work might be performed effectively.

These recommendations had been implemented by nearly all the 48 States in their planning. They would be used by the United States Public Health Service in allocating Federal funds for health purposes to the various States.

Dr. MELVILLE MACKENZIE (Ministry of Health), describing a recent visit to the United States, said he was impressed by the enthusiasm of all public health workers. Co-operation between the public health and university authorities was very close. He gave instances where the statistical approach to problems had been most helpful in planning future public health programmes. Public health nurses were highly trained and not considered eligible to practise until 28 years of age; they tackled a wide range of health problems in home visiting. Laboratory facilities in the best public health departments were highly developed; in some cases it was obligatory for the practitioner to submit specimens—e.g., in a suspected typhoid case—and health officers were kept informed of possible foci of infection by receiving copies of laboratory reports. Diphtheria immunization tended now to be combined with immunization against whooping-cough, and was undertaken when the child was 3 months old. In some cases it was thought necessary to inoculate all children against tetanus. In many health centres the social amenities for parents and children avoided the atmosphere of a place to which people only came when they were ill. Health education, including that of the medical profession, was very actively pursued, and wide use was made of wireless, schools, etc., for health propaganda.

Dr. A. TOPPING (U.N.R.R.A.) felt that health propaganda was sometimes considerably distorted by the Press in America. He was surprised to find that payment was sometimes required for essential treatment such as plasma transfusion. He agreed that American public health nurses had a long and exhaustive training, but thought that the best type of health visitor in this country was second to none. The ratio of 3 hospital beds per 1,000 population was only half the number aimed at in this country. (Col. Leavell later explained that the figures he had given were minimal.)

Dr. F. J. BENTLEY (L.C.C.) derived comfort from the fact that the United States had found it difficult to avoid some of the complexities of public health administration which worried us in this country. He was assured by Col. Leavell that the shortage of nurses was equally acute in America, where the public health service was subsidizing the training of 60,000 nurses. In reply to other questions Col. Leavell said that any State could refuse to adopt the recommendations for reorganizing its health services, although some financial pressure could be exerted. Medical care (including hospital provision) was unfortunately not always the responsibility of the public health department. In matters of housing the department was in an advisory position only. The largest local health units would be in the big towns and might include populations up to 250,000, but units of this size would be exceptional.

EVOLUTION OF SPEECH ORGANS

At the recent annual meeting of the Manchester Medical Society Mr. V. E. NEGUS gave an address on the evolution of the speech organs of man.

He said that sound had been adopted by man as a means of communication because of its many advantages; alternatives were gesture, olfaction with its very limited application, and touch. Sound could be used in the dark; it would pass obstacles which impeded vision and travel against the wind; it could be used to express ideas; and it left the hands free. The human being's vocal apparatus consisted of the sound-producing larynx, with a series of resonators—the lungs, the pharynx, nose, and mouth—to amplify and modulate the mixture of pitches resulting from vibration of the vocal cords. The larynx was evolved as a valve to protect the lungs and not as a vocal organ; it had undergone many modifications. The simple muscular sphincter of lung fish had changed in higher animals to a more complicated organ with cartilages which provided a framework and thus facilitated opening and closing. Herbivorous animals had a special modification to help in swallowing large quantities of semi-solid food; the margins of the larynx were raised to prevent fluid entering the air tract. Animals of herbivorous ancestry which took to climbing trees had a secondary valve, usually called the vocal cords, the object of which was to assist in fixing the thorax when the fore-limbs were in use. In keen-scented animals the larynx was apposed to the nasal passages in order to direct the air stream through the olfactory area and thus to maintain a keen sense of smell. Man did not rely on powers of scent; in him the larynx had descended in the neck as a result of recession of the jaws and the adoption of the erect posture, and a gap was thus produced between the larynx and the palate. The pharynx thereby increased in size. The pharyngeal, buccal, and nasal resonators were capable of great variation in size and shape.

In reply to Prof. Wood Jones, Mr. Negus said that the air passages and larynx in the whale, which had no sense of smell, were closely connected to enable the air to be warmed and for inspiration to take place without the necessity for emptying the mouth and pharynx of food and water. Dr. T. H. Blench referred to the beating of the chest by gorillas and the axillary air sacs in the orang as accessories in the production of sound without using the chest muscles. Mr. Negus concluded that animals living in dense or wooded country required voice and methods of sound production, while those living in open country, such as the giraffe and vulture, did not need them.

The report for 1944 of the Institute of Physics shows that its membership increased by some 15%. Despite wartime difficulties the Groups and the Branches both at home and over-seas held meetings and conferences covering a wide range of technical and professional subjects. A new and successful venture was the publication of a series of lectures given before the Industrial Radiology Group as a *Handbook of Industrial Radiology*. The *Report on the Teaching of Mathematics to Physicists* prepared jointly with the Mathematical Association was published during the year.

Correspondence

Poliomyelitis in Malta

SIR,—With reference to your leader in the *Journal* of June 2 on poliomyelitis in Malta please compare my conclusions relative to the same outbreak at pages vii and viii of the annual report of the Medical and Health Department, Malta, for 1942; the statistics were revised in the report for 1943. My opinion was that spread was by contact droplet infection, and other means excluded. This is now confirmed by Seddon. I left open origin of outbreak, but inclined to importation of fresh strain of virus from abroad. Information now given by Seddon, not available to me then—that 200 airmen arrived in Malta in October, 1942—favours my opinion that virulent infection was freshly imported, especially when place of origin and nationality of airmen are considered. I laid emphasis on the importance of healthy carriers in introducing and disseminating infection, and said that the appearance of paralytic cases was not an absolute index of date of introduction or commencement of infection. The relative immunity of adult Maltese may be due to a racial factor; this disease is always infantile in Malta.—I am, etc.,

A. V. BERNARD, M.D.,
Late Chief Government Medical Officer;
President, Malta Branch, B.M.A.

Malta (by cable).

Portable Surgical Hospitals for China

SIR,—You will recall that in 1942 the War Organization of the British Red Cross and Order of St. John sent out to China a hospital unit consisting of doctors and nurses, who, under enormous difficulties, have rendered some aid to the wounded soldiers and the sick and wounded refugees in the provinces of Hunan, Kweichow, and Yunnan.

Now that victory has been attained in the West it is fitting that we should pay further and closer attention to the needs of China, our ally in the Far East. Accordingly the War Organization plans to send out the personnel and equipment for four portable surgical hospitals to work with the advance troops of the Chinese Army now being reorganized with the assistance of United States Army personnel. These portable surgical hospitals will consist of mobile teams with their own transport and equipment. They will probably have to operate from tents and live under canvas. Part of the staff will be highly trained Chinese. To complete the staff of these portable surgical hospitals the War Organization requires the services as soon as possible of 12 doctors (men with surgical experience) and six mechanics (if possible with first-aid training). Applicants, who must be young men, medically fit, should apply in writing, giving age and qualifications, to Dr. H. Gordon Thompson, China Section, War Organization of the British Red Cross and Order of St. John, 14, Grosvenor Crescent, London, S.W.1.

I trust that the response to this appeal for help may be as swift and effective as the need is both desperate and great.—I am, etc.,

PHILIP CHETWODE,
Field-Marshal, Chairman.

War Organization, B.R.C. and Order of St. John,
London, S.W.1.

Teaching of Physiology

SIR,—Dr. Ff. Roberts's article on realism and humanism in medical training (June 16, p. 848) will, I am sure, have been read with interest by teachers of the pre-clinical subjects, for it is always of value to have the comments of those whose criticisms are not inhibited by recent practical experience of their subject. Teachers of physiology are only too well aware of the shortcomings of the present courses, and I noted with disappointment—though not with surprise—an absence of any constructive proposals.

Dr. Roberts regards as excessive the disproportion in present-day teaching of physiology to medical students between factual knowledge and practical experimental experience. I entirely agree with him, but few will take seriously his assertion that the cause is indifference or incompetence on the part of the teachers. There are, as a matter of fact, several considerations which make it difficult, if not impossible, in the present state of things, to increase materially the relevant experimental practice of pre-clinical students in physiology, desirable as this would be. These difficulties are so well known to teachers of physiology that I am inclined to think we too readily assume that they are also appreciated by those who are now improving the education of the medical student.

1. *Size of Classes and Practical Work.*—The steady increase in the size of classes together with reduction in the time available for practical physiology (owing to the introduction and expansion of other subjects) has had a considerable influence on the nature and scope of practical classes. Experiments and demonstrations which are suitable for a dozen or so students who can spend several hours over them are out of the question with a hundred or more students who cannot devote more than two or three hours on any one occasion.

2. *Use of Animals by Medical Students.*—Despite the large size of modern classes and the limited time available, it would nevertheless be a simple matter for the student to perform for himself many of the important mammalian experiments which he reads about in the books but sees only as demonstrations, if at all, but for the following facts.

Students are forbidden by law to experiment on any vertebrate animal except one which has been decerebrated by a demonstrator; the use of anaesthetized animals—even rats—is not allowed. Now it takes a certain amount of skill with the aid of an assistant and some ten or fifteen minutes to decerebrate a cat (or rat); obviously, therefore, the necessity for preliminary decerebration severely limits the extent to which mammalian experiments can be included in practical classes for medical students. If the use of anaesthetized animals were permitted, it would at once be possible to effect a great improvement in the scope and teaching value of practical physiology classes; the use of frogs could be restricted to those few experiments for which they are actually the most suitable, and a large number of valuable experiments carried out by the students themselves on mammals. Relaxation of the law in this respect would render superfluous many animal demonstrations; but there would still remain a large number for which the use of an unanaesthetized animal, previously prepared by feeding, aseptic surgery, or training, is essential—e.g., many demonstrations on the functions of the nervous system, digestion, absorption, the semicircular canals, and the reproductive organs (to quote only Dr. Roberts's examples of subjects at present learned indirectly from the book).

Such demonstrations cannot be shown to students in this country because no experiment may be performed on an animal for demonstration purposes unless it is anaesthetized throughout and is killed before it recovers consciousness (Certificate C). Moreover, since such experiments may not be demonstrated, it follows that no films can be made of them; the teaching films of animal experiments shown in this country have either been made abroad or involve only completely anaesthetized animals. A little thought will show the vast number of valuable demonstrations and films which it is impossible to make or show for teaching purposes.

3. *Supply of Cats and Dogs for Teaching and Research.*—Even supposing the present restrictions upon the use of animals for medical teaching and research were removed or modified, there would still remain a further difficulty which bids fair to become the most serious of all—namely, the supply of cats and dogs for these purposes. I doubt whether any teaching school in the country is able at the present time to count upon a regular supply of six cats and dogs per week. Our dwindling supplies of these vital necessities for research and teaching are obtained from private animal dealers; we are entirely at their mercy in the matter of prices, which are steadily rising (cats now cost 6s. to 7s. each and dogs from 12s. 6d. to £2). In this city alone last year *more than 30,000* stray cats were destroyed in the lethal chamber by the R.S.P.C.A.; and the use of stray dogs for experimental purposes is forbidden by law.

My own appreciation of the extent to which the teaching of physiology in this country is obstructed by the obsolete restrictions to which I refer is increased by my recollections of the methods of teaching practical physiology to medical students that I was privileged to observe in 1939 in the medical school of Northwestern University, Chicago, Ill., U.S.A., under the direction of Prof. A. C. Ivy. An ample supply of stray dogs was made available by the city authorities for medical teaching and research; and the well-balanced and extensive course of practical instruction provided for pre-clinical students included the performance, on anaesthetized dogs, by students working in groups of four (operator, assistant, anaesthetist, and clerk) of a considerable number of experiments on the circulation, respiration, digestion, absorbtion, excretion, lymph-flow, etc. In addition each group performed at some time towards the end of their course an aseptic operation on an anaesthetized dog (splenectomy) and were responsible for the after-care of the animal. The class also witnessed demonstrations on unanaesthetized dogs provided with gastric pouches and similar preparations which were being used in the department for research.

These students went on to their clinical work not only with an extensive practical experience of mammalian physiology and the techniques employed, many of which are, of course, common to medicine and surgery, but they carried with them also an abiding appreciation of the experimental method as an approach to clinical problems; and a surprising proportion of them returned during and after their hospital training, on their own initiative, to do research—often of very high standard—upon problems directly related to their clinical work.

We all want to see the standard of physiology teaching to medical students raised higher in this country than anywhere else in the world, but we might as well admit that we are at present a long way from this ideal, and shall remain so while we are prevented from giving to medical students that practical experimental experience in physiology which they ought to have, and which, indeed, they may now receive abroad, if they are to assimilate the enormous mass of facts with which they must deal.—I am, etc.,

Department of Physiology, University of Liverpool. R. A. GREGORY.

Trench Fever as a Cause of Pyrexia in P.O.W.s

SIR,—The following case of trench fever in a batch of some 300 or more repatriated P.O.W.s is of interest, and might help to explain some cases of pyrexia that might be occurring among the many thousands of P.O.W.s now on leave in this country.

The patient, a South African, aged 33, was admitted on April 18. He gave a history of 3½ years' imprisonment, during which time he was in good health except for two relapses of malaria. He was sent on the march and developed diarrhoea. On admission he was moderately undernourished, skin dry and scaly. There were several louse bites on his arms, abdomen, and legs. He was afebrile, but three days after admission he complained of a frontal headache and had a temperature of 100° F. His heart and chest were normal, and his abdomen was distended. Liver and spleen were not palpable, there was no glandular enlargement, and his urine was normal. No abnormal organisms detected in faeces; the haemoglobin was 73%, with a total of 4,100,000 R.B.C. and C.I. of 0.9, total leucocytes 6,000.

His temperature subsided within 24 hours and he was allowed up. Ten days after this he had a second attack of fever, and this time complained of aching pains in the shafts of both tibiae and profuse sweating. There were still no abnormal physical signs except for some conjunctival injection. A blood count taken at this time showed haemoglobin 87%, leucocytes 12,000, neutrophils 60%, lymphocytes 4%, and monocytes 6%, E.S.R. 18 (Wintrobe). No parasites were seen in a blood smear taken at the height of his fever.

Subsequently he appeared well, and five days later had recurrence of fever with sweating and deep aching pains in both shins. His agglutination reactions to *Br. abortus*, *B. proteus*—OX 19, OX 20, OX K, were negative. A blood culture was sterile. Since then he has had four bouts of pyrexia, average 100°, occurring every 5 days with shin-bone pains. During the interim periods he feels very well.

The clinical picture of 5-day fever with shin-bone pains, the negative blood findings, and the history of louse infestation before admission make it clear that this is a case of trench fever. Treatment has been symptomatic, salicylate sufficing to relieve pain. Each bout is less severe, and the last expected bout of fever has not occurred. Sedimentation rate is still raised.

I am indebted to Dr. Robinson of the pathological laboratory for his assistance and to Major-Gen. H. H. Blake for his permission to submit this.—I am, etc.,

Stoke Mandeville Hospital, Aylesbury. J. E. DAVIES.

Treatment of Unconfirmed Amoebiasis

SIR,—It has been repeatedly stressed in recent publications that the use of emetine alone in the treatment of amoebiasis is to be condemned. The following type of case presents a problem which, according to hospital physicians in Ceylon, is not uncommon.

An engineer aged 26 complained of sore throat, headache, and pain in the right hypochondrium on respiration, one day after the ship reached a Ceylon port. He had no previous or present history of diarrhoea or similar pain, though sore throats and headaches were frequent. On examination an audible and palpable rub was noted in the right hypochondrium, basal rhonchi, large red tonsils, T. 103°. No other abnormal findings. His temperature fell to normal in three days, but the pain and rub persisted for three weeks in spite of rest in hospital ashore. Chest *x*-ray, differential white cell count, urine, and stools examined for cysts were normal. Apart from his pain he felt and looked fit. On return to the ship he was given a ten-days course of emetine hydrochloride, and local signs and pain disappeared after the fourth injection.

Hurst describes a supposed amoebic hepatitis in which the only symptom may be malaise and the only signs tenderness over the liver and an abnormal laevulose tolerance test. Sigmoidoscopy and stool examination and white cell count show no abnormality. He recommends repeated short courses of emetine hydrochloride for these cases.

Is a full course of emetine, emetine bismuth iodide, stovarsol, and chinoform justifiable in cases of subacute hepatitis which respond rapidly to emetine hydrochloride but have no amoebae in their stools, or evidence of ulceration on sigmoidoscopy?—I am, etc.,

RICHARD MEYER, M.B.,
Late Ship Surgeon,
London, W.1. Elderman Bucknall S.S. Co., Ltd.

Malaria and Salvarsan

SIR,—With the return of thousands of malaria-infected soldiers from the Tropics a timely warning against the dangers of malaria in general and of the administration of organic arsenicals in particular—either for treatment of syphilis in malaria patients or for other purposes—seems only too appropriate. The danger is especially great, as many people may suffer now and later on from malaria without knowing it; they might even have been infected in this country, where, as we all know, anopheles mosquitoes do exist. A friend of mine has already detected a case of malaria in an officer nine months after his return from Africa who never had an attack whilst abroad.

Administration of salvarsan preparations can give rise to a cerebral malaria which, if unsuspected, only too often tends to take a rapidly fatal course. In a publication, "Häufung von Malariatodesfällen nach Salvarsaninjektionen" ("Increase in Cases of Death from Malaria following Salvarsan Injections") (*Klin. Wschr.*, Vol. I, No. 28), 23 years ago, I stressed the importance of the necessity always to think of a possible malaria in febrile conditions of unknown origin, particularly in syphilitics and those patients whom one intends to treat with organic arsenicals for other reasons.—I am, etc.,

London, W.1. ERNST SKLARZ.

Methods of Venepuncture

SIR,—It goes without saying that any reasonable person will agree with Dr. Mendelssohn and Prof. Witts (June 16, p. 852) that everything used for venepuncture should be sterile wherever possible. I think, however, that they underestimate the difficulties of the under-staffed laboratory where the pathologist must do everything himself and at the same time handle large numbers of patients and specimens. The counsel of perfection is not easily attained under such circumstances, and I think that the method I have described has given too good results to be ignored. I may mention that the figures I gave (of over 40,000 such punctures) were not a mere guess but were founded on those taken from my card indices for annual return purposes.

As to the risk when the vein is missed, it should not be necessary to pull on the piston, as the blood appears spontaneously in the syringe when the vein is tapped. With regard to the possibility of bruising or haematomata resulting from the method, while it is impossible to ignore the impressive array of authorities that they quote, it may, I think, be sufficient to say that with this method such sequelae just do not occur; indeed, it is hard to see how they can. So far as "following-up" is concerned to ascertain the incidence, if any, of infection or haematoma, it may be mentioned that these cases afford an almost unique opportunity to do so, as they are cases of chronic rheumatism attending a large clinic, nearly all of them attending for many months, and some attending for a number of years, most of them being seen at frequent intervals. I am still seeing some who first attended in 1933. I may say that at no time has there been any evidence of jaundice or other infection.

I am, of course, only too acutely aware that it would be fatally easy to murmur *Experientia docet* and leave it at that. It might easily be alleged that no case of infective jaundice has yet come along to infect the instruments, though with such a large number of cases the possibilities would seem to be considerable. I am as anxious as Prof. Witts to avoid any mischance, and can assure him that he is mistaken in thinking that I treat this important part of my profession too lightly; I am quite prepared to use any better methods that may offer themselves. I do indeed remember the passively filled tubes used at Guy's years ago, but I also remember how extremely bad they were, how impossible to use on very small veins, and also what a row I got into with the contemporary professor for venturing to criticize them. In order to obtain enough blood before clotting occurred, cruelly large needles had to be used, even when a mouth-suction-tube was employed. I well remember how the patients, quite rightly, objected to them, and I have known them refuse to have any further punctures made with them after one experience. I soon gave them up, and used apparatus of my own. A venule is not bad, but it is hard to collect measured amounts with one, and it is never possible to be sure that the vacuum is really there when needed, though I have often re-evacuated them, using the makers' own method.

One thing, however, does emerge from this discussion—that venepuncture should not be entrusted to inexperienced persons. As house officers we always used to do them ourselves when they were not done by our superiors, and it is hard to see why the house officers of the present day should delegate the task to subordinates; with all due respect to those able women, it should be no part of a sister's duty. If such delegation is avoided, the risks of disaster such as that recently described should be eliminated.—I am, etc.,

Haywards Heath. J. W. SHACKLE.

Mono-articular Osteo-arthritis of the Hip

SIR,—In an interesting article on treatment of this condition Mr. Grant Waugh (June 23, p. 873) has stressed the value of acid injection of the joint. His technique, however, consists of two parts: (1) the injection and (2) very gradual manipulation, and *flexion-abduction-extension exercises, without weight-bearing, consistently and perseveringly carried out by the patient* (my italics). In my view it is these exercises that are the crux of successful treatment for this condition. They are simple and consist of: (*a*) flexion of thigh and flexion of knee on chest assisted by the patient's hands; (*b*) straight-leg raising to the perpendicular and then allowing the leg to fall at right angles to the trunk; and (*c*) abduction of both legs with the feet inverted. The patient should be taught how to do the exercises rhythmically, without jerk and with proper intervals of relaxation. Further, each exercise should be done up to a dozen times each morning with the patient lying on a bed or the floor. Then, if carried out consistently and perseveringly, there should be no need for injection of the joint or manipulation.—I am, etc.,

Bath. G. R. P. ALDRED-BROWN.

Puerperal and Lactational Mastitis

SIR,—With reference to the letter (June 23, p. 886) from Dr. V. Mary Crosse giving the incidence of mastitis in Birmingham during the past seven years I should like to take the opportunity of correcting a misapprehension on the part of Dr. Crosse. The figures published by me do not refer to the city of Dundee but to a much smaller town of some 43,000 inhabitants.—I am, etc.,

Public Health Department,
Dundee.

A. A. FULTON,
Maternity and Infant Welfare Medical Officer.

"Predisposition" to War Neuroses

SIR,—I concur with the views expressed by Dr. F. Dillon (April 21, p. 570). A full investigation into the records of the Service man who has seen action beyond what might be termed a given saturation period in this war is indicated. This is naturally only feasible if the Service medical branches either conduct it or open their otherwise secret records to outside investigators. A "combined operation" would be conducive to a balanced view, seeing that the rehabilitation period on discharge from the Forces would needs have to be included.

The personal as well as the family history of the patient would, in my submission, aid both the personnel selection departments of the three Services when the conscript enlists and for posting purposes on completion of initial training, and the Service medical branches who watch over the progress of the enlisted as a fighting man.

Dr. William Brown in his *Peace and War* (*Essays in Psychological Analysis*) has shown convincingly that war itself is a state of national neurosis. Neurotics of certain types appear and have proved themselves to be capable of excellent and brave conduct under fire, whereas the day-to-day existence of the average civilian would produce recurrent lapses into some form of delinquency or abnormality.

In my experience, however, the junior leader must have a stable personality. Leadership in the face of the enemy after all requires coolness as well as audacity, appraisal as well as love of danger, a feeling of high obligation both for the sake of personal prestige and in view of the position in the formation and the responsibilities that go with it. This equilibrium would appear to be lacking in a psychopathic personality.—I am, etc.,

Hempstead, Long Island, N.Y., U.S.A. K. H. STEIN.

Psychosomatic Factors in Disease

SIR,—Your correspondent Dr. Victor Leitner, in his letter on psychosomatic factors in disease (Feb. 17, p. 235), states that "it is just as dangerous to label as neurotic a patient with a *real* complaint as vice versa." What a deplorable observation! Does Dr. Leitner really suggest that the neuroses are not real complaints? His injunction to remember that "some chronic conditions of slow and insidious onset—e.g., pulmonary tuberculosis and pernicious anaemia"—may simulate neurotic illness long before any definite clinical signs can be elicited is important enough to warrant more than "a careful taking of the family history in cases of this sort." It cannot be too strongly emphasized that any fault in function, efficiency, or stability should be interpreted as a fault of the entire body mechanism and not as some purely local upset quite divorced from the rest of the body.

In endeavouring to identify whether an illness is predominantly physical or psychogenic a careful history is imperative. Search should be made for predisposing and precipitating factors. The duration, intensity, and appropriateness of the symptoms should be carefully elicited and considered, and a possible motive for the disability suspected when the symptomatology generally or the emphasis laid on a particular symptom is unusual, exaggerated, or incongruous.

For administrative purposes it is obviously important to reach a diagnosis. I cannot agree that the "labelling of a patient as neurotic" is in any way "dangerous." Such a classification should in no way preclude the early identification of organic criteria if these present themselves, provided that the physician in charge of the case is "psychosomatic conscious."—I am, etc.,

S.E.A.C.

E. STUNGO,
Major, R.A.M.C.

Venereal Disease Prophylaxis

SIR,—For years I have scanned medical literature in the hope of finding the announcement of a prophylaxis whereby "the man in the street" should, on occasion, protect himself from infection with the germs of venereal disease. In the meantime I have often seen in non-medical literature statements to the effect that in various parts of the British Empire the Government has had to spend larger sums on the treatment of venereal diseases than (say) on "poor relief."

In the last war, as a battalion medical officer, I had no great difficulty in carrying out the commanding officer's request that the unit be kept free from the incidence of venereal diseases when we were in certain areas. In this war during the past four and a half years I have not seen a single case of syphilis, gonorrhoea, or chancroids arising among the various Service units of whom I have been in medical charge. I ascribe this to the fact that men have fully co-operated in the work, after hearing that the prophylaxis advised would be absolutely effective and that its employment after every exposure would be as sure a sign of their culture as the daily use of their tooth-brushes, and that venereal diseases can only infect the ignorant, the careless, and the helpless. In some areas showers of well-meaning but inaccurate and rather hysterical pamphlets have proved, as I understand from medical and police authorities, a godsend to the gonococcus and the spirochaete, which will continue to sweep forward like the four horsemen of the Apocalypse until the medical profession mobilizes the forces of prophylaxis against them.—I am, etc.,

A. C. KIRTON.

The Cloistered Nurse

SIR,—There is much discussion to-day about the difficulty of finding candidates for the nursing profession. Even now there are hospital authorities who ignore many aspects of the problem.

Some years ago, when in municipal employ, I was acutely conscious of certain handicaps and discomforts of hospital life. I had a bed-sitting-room into which the sun never shone; here the day and night were disturbed by screams from the children's ward, groans from the old men, a gramophone above, and a piano below. Such "noises off" made life somewhat trying and were also audible from the nurses' quarters. On more than one occasion I was going round a ward with a junior nurse, in the absence of the ward sister or staff nurse, and had an opportunity to learn quite a lot. Several times I found these girls acutely unhappy, and several times I had to rush them into a side ward where they had a good cry. Between sobs I used to hear, "Oh, I've been in London five years and I haven't been in anybody's house once." As a Londoner who has been lonely in London I think I know what this means. If there is a normal then it is in the house and home and not in an institution. Both nurses and doctors have not only to work, but also to live, with people with whom they may have no affinity at all. One is tolerable for a few years in one's youth. The two together may become unbearable. Yet it is quite common to meet members of hospital staffs who are resident and who likewise confess in candid moments that they feel strange in a private house.

Now this is on the border line of sanity, and we should see to it that those who deal with the sick never get into this state. It is not so much a question of money as of imagination and humanity. After much effort I did manage to start a social club for the nurses. The opposition and the apprehensions which this step excited were quite amazing. Even now senior nurses are exposed to dragooning and coercion quite out of keeping with their status and their age. Municipal authorities are, I think, worse offenders than those of voluntary hospitals. It has not occurred to some that at the bedside something should go out of the medical and nursing attendants into the sick patient. And this intangible something, some little courage and cheerfulness, cannot be imparted if the staff, by the conditions of their living and employment, feel unhappy and humiliated. Everyone who has the care of sickness must feel a "person" to be able to do any good. It is to be hoped that in post-war medical schemes this point will not be overlooked. —I am, etc.,

B.L.A.

G. C. PETHER,
Major, R.A.M.C.

Examinations for Nurses

SIR,—One point in Mr. Wilfrid Adams's excellent letter (June 16, p. 857) drawing attention to the increasing burden of bookwork laid upon the student nurse seems to call for comment. He says that her studies are on a par with those of a medical student. This is not quite true in so far as the medical student does at least dissect the body, look down a microscope, use a stethoscope. He is not required, as the nurse is, to memorize like a parrot textbook descriptions of such things as the microscopic structure of tissues, the appearance of the commoner micro-organisms, the signs of pneumonia.

Those of us who are accustomed to teach student nurses must often have reflected upon the waste of time and effort involved in imparting and acquiring all this second-hand information which can have no greater practical or educational value to a nurse than a knowledge, say, of the anatomy of the fly's eye or the markings on Mars.—I am, etc.,

Hove.

CONSTANCE OTTLEY.

SIR,—As a State-registered nurse I have been reading with great interest the correspondence on the standard of the nurses' examination papers, and hasten to write in defence of the General Nursing Council and against lowering the standard.

In his letter of June 16 (p. 857) Mr. Wilfrid Adams states that by studying for such examinations a nurse becomes less proficient. Is this possible? A nurse practises her nursing procedure for 54 hours weekly and does all her studying and attends the majority of her lectures in her off-duty time. Whereby does the patient suffer? Or doesn't Mr. Adams think 54 hours weekly is long enough to practise nursing procedure? The knowledge of the course of disease, the treatment of it, and what complications to watch for surely impresses a nurse with the importance of her nursing care much more than orders issued by a "good sister" to do this or not to let the patient do that. Knowledge of the results which her efficient nursing is likely to produce surely urges her to put that little extra effort into her work that would be lacking with ignorance. Certainly encourage the art of nursing as much as possible, but what use would the art be in an emergency unless combined with knowledge? I would therefore say: teach her the technical side, and any nurse of average intelligence who is interested in her work will apply that teaching to the betterment of her nursing procedure.

There is no arguing the fact that there is a shortage of nurses, but improving the accommodation and recreational facilities is more likely to encourage a girl to the profession than cutting out some of the interest from the work; and increasing the domestic staff of hospitals would give the nurses more opportunity to practise the art of nursing. Even as theatre staff nurse of a big general hospital I spent many hours a week scrubbing floors when I could have been more profitably employed in teaching junior nurses.—I am, etc.,

Redruth.

JEAN L. PEARSON.

The Position of Medical Research

SIR,—I have searched the various political effusions dealing with proposals for a new era in health together with the more cautious proposals of medical bodies, and am surprised to find little or no attention being paid to that fountain-head of medical progress—namely, medical research.

At the present moment the greatest advances in medicine—such as sulphonamide therapy and penicillin therapy—come to us from the field of biochemistry. The opportunities available for those of us with the necessary academic qualifications to justify us working in this field are extremely small and poorly paid. Few can afford to exist upon the quite inadequate salaries—£400 a year is about the average—at present offered. Some of our best brains are earning good money in consulting medicine or surgery, and it is quite uneconomic to expect these men to sacrifice part or the whole of their incomes for the good of mankind.

Were it not for the security and fair pay offered by commercial concerns I doubt if we should have progressed as far as we have done. In industry one of the highest-paid employees is the research chemist. Why cannot research workers in medicine have similar security free from financial stress? In art it would seem necessary to be down at heel, penniless, and half starved before one can produce a masterpiece, but surely this should not apply to medicine. Perhaps the large insurance firms would find that a dividend could be paid from financing research in preventive medicine; it would certainly cut down the number and extent of the claims made against them for sickness and probably premature death.—I am, etc.,

Bebington, Cheshire.

JOHN HERBERT HANNAN.

Housing the Returned Consultant

SIR,—Col. T. W. Preston (June 23, p. 888) has touched the root of the problem. The "Harley Street tradition" dates from the days at the close of the last century when the majority of London consultants lived in this and neighbouring streets. Now that few actually live there, and those who practise are outnumbered by the "consultoids," the tradition has no foundation and must sooner or later collapse. The future of consulting practice lies with the hospitals—that is, consultants must see private as well as hospital patients at their hospitals and admit such as need institutional treatment into private or contributory wards. Only so can group investigations be arranged without loss of time or needless expense. Only so can the public be protected from exploitation and assured that they are getting specialist service in exchange for specialist fees. If hospitals will put facilities for interviewing and examining private patients, with reasonable attendance and secretarial help, at the disposal of members of their staffs, the majority of consultants returning from the Forces and the E.M.S. will gladly turn their backs on the *juju* of the brass plate.—I am, etc.,

London, N.W.8. W. H. OGILVIE.

SIR,—Major H. B. Stallard's recent letter has raised a wider issue. He very rightly stresses the difficulties confronting the returning Service doctor. These difficulties are in great part due to the inundation of the fields of British medical practice by alien doctors, who, in the first instance, sought sanctuary in this country. Our profession not only offered them hospitality but the means of livelihood in their need by admission to our *Medical Register*. The very political conditions which drove these men from their homelands have been reversed by the Allied Armies, and with these Armies went our own doctors: and here is the crux of the matter—many of our doctors are still there. For many of these this has meant the sacrifice of nearly six of their peak earning years. How is it possible to justify the retention of one British doctor in liberated Europe while there remains one refugee doctor in this country? Surely his claim to practise his own profession among his own folk is the privilege of any doctor. He should be afforded every facility to do so.

We have no doubt that this facility would be very acceptable to every British doctor whether still over-seas or, having served in the Forces, is now attempting to resume his pre-war vocation.—We are, etc.,

L. T. CLARKE,
Major, R.A.M.C.
R. S. MACHARDY,
Major, R.A.M.C.

Obituary

Dr. GEOFFREY HEMPSON died on June 2 after a long illness. He was educated at Sherborne and University College Hospital, taking the Conjoint qualification in 1915. He immediately joined the Army and served with distinction, reaching the rank of captain. On his return home he took the D.P.H., and after house appointments at U.C.H. and the Brompton Hospital, decided to specialize in tuberculosis, gaining the post of senior assistant medical officer at Pinewood Sanatorium. It was during his years there that he laid the foundation of that skill and knowledge which led to his appointment in 1927 as medical superintendent of the Royal National Hospital for Consumption, Ventnor, which he was to serve unremittingly until ill-health compelled his retirement in 1942. Geoffrey Hempson (writes A. K. M.) was above all a physician, skilled at his specialty and able to command the confidence of his patients through long spells of treatment. His great charm of manner and his innate kindness gained him the affection as well as the respect of his patients, and indeed of all the hospital staff. Nobody who worked under him will forget his kindness and courtesy. During his tenure of office considerable developments in the treatment of tuberculosis occurred, for this was the era of the wide development of artificial pneumothorax and thoracoplasty: Hempson kept the hospital fully abreast of these modern methods, and it was during this time that major thoracic surgery was first undertaken there by Tudor Edwards. He proved a skilful administrator, able to get discordant personalities to work together, and the building programme carried out at this time owed much to his wise advice. His love of animals and his knowledge of them were remarkable, and he was always to be seen early in the morning exercising his dogs, which he bred and showed with success. Hempson excelled at amateur theatricals and was never happier than when coaching the hospital staff for the annual Christmas show. His enthusiasm, his striking personality, and his histrionic ability made it difficult to live up to him on the stage, and he was the mainspring of a long succession of successful shows. The reorganization of the hospital to take casualties under the Emergency Medical Scheme threw a burden on Hempson; for his conscientiousness made him attend personally to the smallest details, and finally his health broke down and retirement became necessary. He leaves a wife and daughter.

Dr. JOHN H. MOIR, who died on June 7, was born at Newhall, in Derbyshire, son of J. H. Moir, M.D. Both his parents came from Aberdeenshire. He entered Aberdeen University as a medical student in 1901 and graduated M.B., Ch.B. in 1907, proceeding M.D. four years later; he also took the D.P.H. "Derbyshire" writes: To all his many friends the death, at 59 years of age, of John Hay Moir must come as a shock. After qualification he became house-surgeon at the Children's Hospital, Birmingham, and later was R.S.O. at Southwark Infirmary, and finally joined his father's practice in South Derbyshire. After the death of his father he remained in single practice until the outbreak of the last war, when he at once volunteered for service. While a lieutenant, R.A.M.C., he was decorated with the D.S.O. for an act of outstanding courage. Later, as a captain, he received the further awards of the Military Cross and bar, and was also twice mentioned in dispatches. His old friends in the 17th Royal Fusiliers and the 20th General Hospital will not forget his work and deeds on active service in France and the Mediterranean. In 1919 he returned to his practice and, when joined in partnership by Dr. E. M. R. Frazer in 1926, removed to the neighbouring district of Swadlincote, where he lived until his death. He was honorary surgeon to the General Infirmary, Burton-on-Trent, and examining surgeon to the Midland Colliery Owners Mutual Indemnity Company. In the latter appointment he displayed a unique knowledge of the application of the Workmen's Compensation Act to medical problems. His death after an illness of a few weeks leaves a sense of great personal loss to his medical colleagues and patients alike. His sterling character and shrewd clinical judgment were hidden under a quiet and slightly deprecatory manner. Though admitting no medical politics, he had the happy knack of contributing original suggestions at medical and lay meetings which carried real weight. Beneath it all lay a fine sense of humour, and many of his witty, and often disconcerting, remarks will be remembered and treasured. Jack Moir was a sportsman who loved life, his friends, his work, and his patients: and his many quiet kindly actions won him the gratitude and respect of all who knew him. Struck down by his fatal illness with appalling suddenness, and knowing he had not long to live, he remained to the end a very gallant man.

The death of Dr. VISHWA MITRA LAMBAH on May 12 has removed one of the most beloved and attractive figures from Bilston, where he practised medicine for many years. Born at Peshawar City, North-West Frontier Province, on April 2, 1887, he studied medicine first in Bombay and then at Edinburgh University, where he obtained the degrees of M.B., Ch.B. in 1912, and B.Sc. in Public Health. In 1914-15 he served in the Indian Medical Service and in 1916 became resident medical officer at New Cross Hospital. From 1916 until his death he worked as a general practitioner in Bilston, where he also held many appointments: acting M.O.H., police surgeon, examiner and lecturer for the St. John Ambulance Brigade, and A.R.P. medical officer to all the works in Bilston. Apart from this, Dr. Lambah took a vivid interest in social activities there and was president of the Bilston Horticultural Society for 7 years and president of the tennis club for 20 years, during which time he did much to improve them. He worked untiringly to promote friendship between the British and Indian peoples and was well equipped to do this, being closely associated with both. He was president of the Birmingham Indian Association, president of the Punjabee Society for 8 years, vice-president of the Indian Medical Association, vice-president of the Chief Punjab Association, and Trustee of the Indian Social Conference. He organized many receptions in London, Birmingham, and Wolverhampton to give us the opportunity of meeting representatives of India. Some notable instances were the receptions given to delegates of the three Round Table Conferences and the Indian cricket team. Dr. Lambah was a philosopher, patient and unassuming, always courteous and considerate—a character that will be sadly missed.—W. H.

Dr. **ALFRED G. S. BROUGHTON**, who had practised at Batley, Yorks, for 45 years, collapsed and died while playing golf at Howley on June 9. He was born in 1875, and after education at the Yorkshire College graduated M.B., Ch.B. of Victoria University in 1900. Dr. Broughton joined the honorary medical staff of the Batley and District Hospital in 1914 and was president 1938–41. He had been closely identified with ambulance work in the neighbourhood since 1907 and received the long service medal in 1924 as surgeon to the Dewsbury and District Corps; he was also a Commander of the Order of St. John of Jerusalem and a J.P. for the borough. He held office as chairman of the Dewsbury Division of the B.M.A. in 1922–3 and again in 1939–43, and had been president of the Yorkshire Branch. He was an enthusiastic musician and a pillar of the Batley Amateur Thespian Society, in whose orchestra he played for several years. His son, Dr. A. D. D. Broughton, also a past chairman of the Dewsbury Division, is serving as squadron leader in the R.A.F.V.R.

We regret to announce that Dr. **ROBERT CRANNA**, of Bolton, Lancs, died on June 12. He had been honorary secretary of the Bolton Division of the B.M.A. from 1923 and was elected chairman in 1939; he had also been a member of the Insurance Acts Committee for the past seven years. Born at Crimmond, Aberdeenshire, in 1876, he graduated M.B., Ch.B. at the University of Aberdeen in 1901 and four years later went to Bolton, where he built up a large practice and was a familiar and greatly respected personality. In 1923 he became honorary secretary of the Local Medical and Panel Committee and in 1935 was appointed its chairman and a member of the Bolton Insurance Committee. For the past four years he had been chairman of the local Medical Board responsible for passing men and women into the Services, and he was chairman and honorary secretary of several emergency committees dealing with practice in the borough. By the medical profession of Bolton and district the loss of Dr. Cranna will be sorely felt; they looked upon him as their counsellor and friend, and few can have given greater service to their fellow-practitioners or have been held in higher regard. He leaves a widow, a daughter, and three sons, two of whom are members of their father's profession, one being a major in the R.A.M.C.

Universities and Colleges

UNIVERSITY OF OXFORD

The Osler Memorial Medal for 1945 has been awarded to Prof. C. G. Douglas, D.M., F.R.S., Fellow of St. John's College.

At a Congregation on July 21 the degree of M.A., *honoris causa*, will be conferred on Col. L. M. Dyke, U.S. Army Medical Corps, officer-in-charge of the 91st General Hospital (Churchill Hospital).

On June 9 the degree of B.M. was conferred on D. F. van Zwanenberg in absence.

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part II (Principles and Practice of Physic, Pathology, and Pharmacology)*: D. G. Abrahams, D. A. Bailey, D. A. N. Barran, A. D. Beard, R. Bellamy, A. M. H. Bennett, J. G. Benstead, M. F. Bethell, P. F. Boreham, A. R. Buckley, A. R. C. Butson, R. E. Church, J. M. Cliff, N. K. Connolly, J. Crichton, D. E. Cullington, W. P. Dallas Ross, I. M. P. Dawson, J. A. R. Debenham, J. A. Dew, A. G. Dingley, A. C. Elithorn, A. M. Elliott, W. S. R. Fenton, J. F. Fisher, J. W. B. Forshaw, S. G. A. Forsyth, J. Gloster, R. A. Green, R. E. Gruchy, E. Halász, P. M. Jeavons, C. H. Kinder, J. B. Lawson, N. B. Malleson, H. R. Mallows, J. R. Moffat, J. P. D. Mounsey, G. R. E. Naylor, K. M. Nuttall, C. J. H. Paget, B. W. Pay, V. R. Pickles, D. A. Pyke, K. E. B. Read, J. W. T. Redfearn, J. A. Rycroft, D. N. Seaton, D. W. S. Sheldon, F. S. Sinker, J. C. Sloper, J. R. Smythies, R. E. B. Spencer, M. G. Thorne, A. J. Underwood Whitney, O. L. Wade, R. V. Walley, J. M. Walshe, W. Waugh, J. A. Waycott, E. J. M. Weaver, N. T. Welford, J. E. M. Whitehead, R. H. Whitworth, D. Wilkes. I. P. Williams, D. Wilson, R. B. Wilson, J. H. F. Wood, I. D. P. Wootton, S. P. Wrightson. *Women:* I. M. S. Chappel, P. J. Coope, C. E. Cooper, M. E. P. Hele, J. E. Keilin, M. M. Mason, L. A. Norris, H. M. Russell, C. N. Smith, J. Whitham, G. B. Wrong.

UNIVERSITY OF EDINBURGH

At a graduation ceremony, held on June 22, the honorary degree of LL.D. was conferred on Lieut.-Gen. Sir Alexander Hood, K.C.B., C.B.E., M.D., F.R.C.S.Ed., Director-General of Army Medical Services.

UNIVERSITY OF GLASGOW

At a graduation ceremony, held on June 26, the honorary degree of LL.D. was conferred on Major-Gen. Sir John Taylor, C.I.E., D.S.O., M.D., I.M.S. (ret.), late Director of the Central Research Institute, Kasauli.

The Harry Stewart Hutchison Prize for an essay on a subject connected with the health of children has been awarded to Marjory N. McFarlane, M.D.

UNIVERSITY OF ST. ANDREWS

At a graduation ceremony, held on June 29, the honorary degree of LL.D. was conferred on William Thomson Munro, M.D.St.And., F.R.C.P.Ed., late director of Glenlomond Sanatorium.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

His Majesty King Farouk of Egypt has sent a donation to the Restoration and Development Fund of the College. This gift is greatly appreciated by the Fellows and Members of the College as evidence of the importance which King Farouk attaches to the maintenance of close relationships between the Royal Medical Colleges of England and the Medical Faculty of the Egyptian University.

The Royal Egyptian Medical Association has sent a gift of £250, which, with the contributions from Egyptian Fellows of the Royal College of Surgeons, brings the contribution of medical colleagues in Egypt to over £1,000. This generous gesture is particularly valued, for the Royal Medical Colleges are very desirous of promoting good relations and cementing friendships between the members of the medical profession in our two countries.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

In the report of the annual general meeting of the College (June 16, p. 857) there was the following omission:

Re-elected to the Council:—*Representatives of the Fellows:* A. M. Claye, H. J. Malkin, C. A. G. Macafee. *Representative of the Members:* H. R. MacLennan.

SOCIETY OF APOTHECARIES OF LONDON

R. J. Mitchell, M.B., D.R.C.O.G., has satisfied the examiners at the examination for the diploma of Mastery of Midwifery.

The Services

Acting Surg. Cmdr. R. S. Rudland and Surg. Lieut.-Cmdr. J. C. Moor, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

Temp. Surg. Lieut. A. K. Mighton, R.C.N.V.R., has been appointed M.B.E. (Military Division) for bravery, determination, and great devotion to duty while serving in H.M.S. *Affleck*, when an explosion caused the whole of the ship to be penetrated by chlorsulphonic acid fumes. In spite of the appalling conditions the casualties were properly tended and the ship brought back to safety.

Major I. Mackenzie, R.A.M.C., has been appointed M.B.E. (Military Division) and Major (Temp.) G. E. Parker, R.A.M.C., has been awarded the D.S.O. in recognition of gallant and distinguished services in the field.

Major J. T. Macdougall, R.C.A.M.C., has been awarded the D.S.O., and Lieut. R. H. Jackson, R.A.M.C., the M.C., in recognition of gallant and distinguished services in Italy.

Capts. W. A. Lopez and L. P. De Souza, I.A.M.C., have been awarded the M.C. in recognition of gallant and distinguished services in Burma.

The following have been appointed to the Civil Consulting Staff of King Edward VII's Convalescent Home for Officers at Osborne, Isle of Wight: Sir Francis R. Fraser, M.D., F.R.C.P., Brig. W. Rowley Bristow, F.R.C.S., Sir Claude Frankau, C.B.E., D.S.O., M.S., F.R.C.S., Prof. J. Paterson Ross, M.S., F.R.C.S., Mr. G. T. Mullally, *M.C.*, M.S., F.R.C.S., Dr. F. M. R. Walshe, O.B.E., F.R.C.P., Brig. D. Evan Bedford, M.D., F.R.C.P., and Surg. Capt. W. D. W. Brooks, D.M., F.R.C.P., R.N.V.R.

The following appointments, awards, and mentions have been announced in recognition of gallant and distinguished services in Italy:

C.B.E. (Military Division).—Brigs. (Temp.) J. H. Bayley, M.C., J. G. Morgan, O.B.E., T.D.; Brig. (Acting) J. M. Mackenzie, O.B.E., M.C.; Brig. (local) F. A. R. Stammers, R.A.M.C.

O.B.E. (Military Division).—Lieut.-Col. R. L. Turner; Lieut.-Cols. (Temp.) T. M. R. Ahern, C. G. Baker, V. J. Downie, D.S.O., M.C., W. H. Gabb, W. Graham, J. H. Hutchison, and K. McNeill, R.A.M.C.; Col. (Temp.) R. L. Raymond and Lieut.-Col. (Temp.) W. H. A. Thorne, I.A.M.C.

M.B.E. (Military Division).—Majors (Temp.) F. W. Bunting, G. J. Cleland, H. G. Estcourt, T. E. Field, D. B. Jagger, B. J. Malley, J. Mason, J. M. McKiddie, R. L. Orchardson, D. L. Owen, and J. McL. Ross; Capts. R. J. A. Macdonald and J. B. Wyman, R.A.M.C.; Major (Temp.) A. K. Dutt, I.A.M.C.

D.S.O.—Lieut.-Cols. (Temp.) J. N. Groves and D. Wright, R.A.M.C.; Lieut.-Cols. (Acting) H. F. T. Macfetridge and N. A. A. Khan, I.A.M.C.

M.C.—Majors (Temp.) H. J. Minford and R. Waddell, Capt. G. Patton, and Lieut. W. S. Roderick, R.A.M.C.; Capts. S. Kesavulu, G. D. Koshal, and S. Mascarenhas, I.A.M.C.

Mentioned in Dispatches.—Lieut.-Cols. M. R. Elliott and E. C. Janes; Majors E. H. Anderson, D.S.O., R. W. Boyden, D.S.O., J. U. Coleman, J. A. Langille, and A. St. C. Rumball; Capt. (Acting Major) H. V. G. Latour; Capts. E. Aiello, R. J. Fassina, W. L. Menzies, J. Mitchell, H. L. Nutik, J. P. Pearce, H. M. Ross, and T. H. Smellie, R.C.A.M.C.

The following appointments, awards, and mentions have been announced in recognition of gallant and distinguished services in North-West Europe:

O.B.E. (Military Division).—Cols. (Temp.) S. O. Dolan, D. L. Kerr, T.D., M. A. Rea, and T. H. Sarsfield; Lieut.-Cols. (Temp.) W. J. M. Brandon, J. H. Dunn, T.D., M. de Lacey, T.D., A. McG. Michie, J. M. Scott, John Smith, and R. S. Taylor, T.D., R.A.M.C.

M.B.E. (Military Division).—Major (Temp.) J. MacP. Harker and Lieut. G. Ollerenshaw, R.A.M.C.

M.C.—Majors (Temp.) H. O. P. McSheehy, C. A. G. Cook, G.M., A. F. Wallace, and Gordon Williams; Capt. G. V. Cole, R.A.M.C.

Mentioned in Dispatches.—Col. G. E. Wight; Lieut.-Col. (Acting Col.) R. H. Cooper; Lieut.-Cols. C. D. S. Leef and D. F. W. Porter; Majors G. A. W. Curric and W. S. Keith; Capt. (Acting Major) J St. C. Moffat; Capts. H. H. Chase, M.M., N. Kaufman, A. H. Megill, A. L. Richardson, and R. W. Tisdale; Lieuts. J. J. H. Connors and B. G. Turnbull, R.C.A.M.C.

The following appointments, awards, and mentions have been announced in recognition of gallant and distinguished services in the Mediterranean theatre:

C.B.E. (Military Division).—Brig. (Temp.) R. A. Hepple, O.B.E., M.C., late R.A.M.C.

O.B.E. (Military Division).—Lieut.-Cols. (Temp.) S. A. MacKeith and A. H. Penman, R.A.M.C.

M.B.E. (Military Division).—Major (Temp.) B. P. R. Hartley and Capt. J. B. Brown, R.A.M.C.

M.C.—Major (Temp.) C. MacT. Hopkins, R.A.M.C.

Mentioned in Dispatches.—Brig. (Temp.) F. R. Sandford, C.B.E., M.C., T.D., Major (Temp.) A. E. Paxton, and Capt. J. P. Irwin, R.A.M.C.

The following appointments and awards have been announced in recognition of gallant and distinguished services in Burma:

C.B.E. (Military Division).—Brig. (Temp.) W. E. R. Dimond, C.I.E., O.B.E., I.M.S.

O.B.E. (Military Division).—Cols. (Temp.) F. K. Bush and R. V. Franklin; Lieut.-Cols. T. E. A. Carr, T.D., and H. R. Sheppard; Lieut.-Col. (Acting) M. MacR. Paterson; Lieut.-Cols. (Temp.) J. B. Bunting, J. B. M. Milne, M.B.E., and R. P. Smyth, R.A.M.C.; Col. (Temp.) F. R. Cawthorn, I.M.S.

M.B.E. (Military Division).—Capt. W. N. Calder, R.A.M.C.; Capts. C. K. Hassan, L. McA. Hogg, and S. S. Grewal, I.M.S.; Capt. (Temp.) M. M. K. Najam, I.A.M.C.

M.C.—Capts. J. A. Chamberlin, H. D. Cockburn, H. M. Jamison, M.B.E., and E. D. Kerr, R.A.M.C.; Capt. C. K. Rao, I.M.S.

CASUALTIES IN THE MEDICAL SERVICES

Died on active service.—Col. Basil Cedric Ashton, C.B.E., I.M.S.

Missing from Singapore since February, 1942, now reported to have died of dysentery as a prisoner of war in Rangoon on Aug. 31, 1942.—Major Hugh McPherson Kilgour, R.A.M.C.

DEATHS IN THE SERVICES

Lieut.-Col. JOHN CHARLES LAMONT, C.I.E., I.M.S., died on June 19 in Edinburgh at the ripe age of 80. He was educated at the Liverpool College and Edinburgh University, where he graduated M.B., C.M. in 1885 with first-class honours. In 1886–7 he was demonstrator of anatomy in the University, an appointment which determined his life's work. In 1887 he entered the Bengal Medical Service and saw active service with the Chin-Lushai Expedition of 1889–90 and the Munipur Expedition in 1891, receiving the Frontier medal with clasp. Three years later he was appointed professor of anatomy in the Punjab University at Lahore, a post that he occupied with distinction until 1906, when he went on leave preparatory to retiring in 1908 from the Indian Medical Service. He immediately took up the post of lecturer on anatomy, University College, Dundee, which he filled from 1906 to 1914, and for three years he was examiner in anatomy at the Royal College of Physicians of Edinburgh. He published a number of papers in the *Journal of Anatomy*, and was elected to F.R.S.Ed. in 1920. In 1914 he volunteered for military service, was re-employed by the Government of India, and was awarded the C.I.E. in 1919. His recreations were fishing and golf, and he was one of the five original members of council of the Clan Lamont Society, founded in 1895. His wife, a daughter of Stephen Adam, of Edinburgh, died in 1935, and in 1940, to commemorate her, he magnanimously gave his house at 7, Merchiston Park to the Corporation of Edinburgh, with the suggestion that it should eventually be used as a rest or convalescent home for their employees, though it has been used during the present war as an A.R.P. depot. Col. Lamont was a sound anatomist with wide interests and many friends and admirers. He had unbroken membership of the B.M.A. from January, 1888.

Medical Notes in Parliament

Diphtheria Statistics.—The following information was given by Mr. WILLINK in reply to questions on June 7: (1) According to returns received from all but a few local authorities in England and Wales the number of notifications of diphtheria during 1944 in children under 15 who had completed the course of immunization was 4,633, compared with 12,455 cases in non-immunized children. (2) Returns from local authorities in England and Wales, which do not include immunizations by doctors in private practice, show that during the year 1944 approximately 386,240 children under 5 and 175,080 between the ages of 5 and 15 were immunized against diphtheria. (3) 23,152 cases finally diagnosed as diphtheria were notified in England and Wales during 1944. Deaths from that disease registered in the same period are provisionally numbered at 934.

Tuberculous Persons in Prisons.—Sir DONALD SOMERVELL told Dr. Summerskill on June 7 that much attention had been given of recent years to prisoners suffering from tuberculosis. *X*-ray examinations were made in doubtful cases; and the prison medical officers received valuable help from the local tuberculosis officers. Care was taken to keep tuberculous prisoners whose condition was infectious apart from others. At prisons where there were several such prisoners special working parties were arranged. Where possible they were employed on light gardening work.

Ministry of Health Nursing Staff.—In the Ministry of Health nursing division the professional staff wholly engaged on nursing questions comprises one chief nursing officer, two deputy chief nursing officers, and 23 nursing officers, of whom three are permanent. In addition there are on the public health side 18 officers with nursing qualifications. The future complements are under discussion.

Vaccination and Death Certificates.—Mr. VIANT inquired on June 7 how many death certificates were received in the year 1944 in which vaccination, vaccinia, post-vaccinal encephalitis, generalized vaccinia, or any other symptom connected with vaccination was given as the cause or one of the causes of death. Mr. WILLINK replied that deaths of the type indicated which were registered in England and Wales during 1944 numbered 12. These were assigned as follows: vaccination 2, vaccinia 2, post-vaccinal encephalitis 4, generalized vaccinia 2, encephalitis myelitis 1. In addition vaccination was mentioned on the death certificate in the case of 1 death assigned to septicaemia.

Training of Midwives in Gas-and-air Analgesia.—In reply to Dr. Summerskill on June 7 Mr. WILLINK said that out of 188 local supervising authorities in England and Wales, 101 had made arrangements before Dec. 31, 1943, for the instruction of their midwives in the administration of analgesics in childbirth. The corresponding figure in the 1938 returns was 30, but there is reason to think that this was an understatement.

Notes in Brief

Mr. Butler states that miners partially disabled by silicosis or pneumoconiosis are eligible for the training and other facilities now provided to assist the resettlement of disabled persons. A number have secured satisfactory employment in this way. These cases will also be eligible for the further facilities to be provided under the Disabled Persons (Employment) Act which are in active preparation.

The Teviot Committee on Dentistry is proceeding with its inquiry as speedily as possible, but Mr. Willink cannot say when the final report will be presented.

The total number of experiments on animals performed during the year 1943 was 1,170,412, a large number of which were simple inoculations and similar proceedings performed either on behalf of official bodies with a view to preservation of the public health or directly for the diagnosis and treatment of disease in man or animals. Figures for 1944 are not yet issued.

The National Insurance (Industrial Injuries) Bill was introduced on June 12 and printed.

Mr. Harold Macmillan states that the release of students from the Services is under consideration.

In the ten-year period April, 1924, to March, 1934, 46,979 dwellings were erected by the L.C.C. For the ten-year period April, 1934, to March, 1943, the figure was 33,836, of which 30,189 houses were completed before new housing operations were suspended in September, 1939.

Payments made by the Exchequer for tuberculosis allowances during the year ended March 31, 1945, amounted to approximately £650,000.

The Trinidad Committee of Investigation on Local Medical Services has completed its survey. The committee's report has been published in Trinidad as a Legislative Council Paper. Copies should be available shortly at the Crown Agents for sale in the United Kingdom.

Medical News

A lecture on the war in the Pacific will be given by Brig. W. A. Hailes, C.B.E., D.S.O., Director of Surgery, Australian Military Forces, in the new lecture theatre, Radcliffe Infirmary, Oxford, at 5 p.m. on Friday, July 13.

The second annual conference to discuss the study of seminology is being held under the auspices of the Family Planning Association, at the School of Agriculture at Cambridge, on July 14 and 15.

A meeting of the Ross Institute Industrial Advisory Committee will be held at the Rubber Growers' Association, 19, Fenchurch Street, E.C., on Thursday, July 12, at 2.30 p.m., when Dr. G. Macdonald will speak on "Recent Developments in Tropical Hygiene." A discussion will follow.

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, July 19 (immediately after the annual general meeting at 5 p.m.), when the president, Mr. Roland Burrows, K.C., will give an address on "Some Thoughts on Crime."

Prof. A. V. Hill, Sc.D., Senior Secretary of the Royal Society, left England on June 26 for Copenhagen to convey the greetings of the society, as representing the men of science of Great Britain, to their Danish colleagues, and through the Academy of Sciences in that country to discuss with them what aid British science can give to the rehabilitation of science and scientific education in Denmark. After three days in Copenhagen Prof. Hill went to Oslo for the same purpose and was received at an extraordinary meeting of the Norwegian Academy of Sciences.

A Standing Advisory Committee on Artificial Limbs has been appointed by the Minister of Pensions under the chairmanship of Sir Charles Darwin, F.R.S. The other members are: Dr. A. W. J. Craft, Lieut.-Col. A. L. Eyre-Brook, F.R.C.S., Mr. E. Ramsay Green, Prof. T. P. McMurray, F.R.C.S.Ed., Mr. L. P. B. Merriam, Mr. George Perkins, F.R.C.S., and Sir A. Rowland Smith. The secretary to the committee will be Mr. K. S. Watt.

Raymond Lewthwaite, D.M., Field Director, and Kenneth Mellanby, Sc.D., Experimental Biologist, Typhus Research Commission, have been appointed O.B.E. (Civil Division) for services to the Forces in India.

A. L. Banks, M.D., M.R.C.P. (Lincoln's Inn), and M. MacGregor, M.D. (Middle Temple), were called to the Bar on June 13.

At the June meeting of the Council of the Royal Sanitary Institute, Mr. David M. Watson, B.Sc., M.Inst.C.E., was elected chairman, to take office on Oct. 1, 1945.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* notifications of whooping-cough rose by 97 cases, of dysentery by 38, and of diphtheria by 15; there were 573 fewer notifications of measles, and 95 of scarlet fever.

There were only small changes in the local trends of scarlet fever: Essex reported 20 fewer cases than last week. Lancashire reported 20 more cases of diphtheria, Essex 11, and Durham 10. Yorks West Riding had 156 fewer notifications of measles, and Kent 153; the largest rise was 112 in Berkshire.

A large outbreak of dysentery, involving 113 persons, was reported from Worcestershire, Malvern U.D. The other large returns were London 49, Lancashire 44, Buckinghamshire 43, Middlesex 27, Surrey 26, Northumberland 24, Warwickshire 15, Devonshire 14, Berkshire 11, Southampton 10.

In *Scotland* dysentery notifications fell by 42—making the total half that of a fortnight ago, and the lowest since the beginning of January. The notifications of diphtheria increased by 10; Glasgow had 11 more cases than last week.

In *Eire* measles notifications rose by 30, and whooping-cough by 26, but those for diphtheria fell by 9. The largest returns for measles were Dublin C.B. 30, and Wexford, Wexford U.D., 13, and for whooping-cough Dublin C.B. 25, and Wexford, Gorey R.D., 12.

In *Northern Ireland* the incidence of diphtheria increased by 7, and of scarlet fever by 10, while whooping-cough fell by 12.

Plague in Malta

The diagnosis of 4 cases of bubonic plague in Malta has been confirmed.

Week Ending June 23

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,237, whooping-cough 1,117, diphtheria 422, measles 6,626, acute pneumonia 376, cerebrospinal fever 46, dysentery 287, paratyphoid 4, typhoid 7.

No. 24

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 16.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

ANY QUESTIONS?

Industrial Dermatitis

Q.—*A patient weighs out and mixes arsenic powder in an atmosphere of alkali powder and cobalt powder. He has a rash on his face. What should be done to prevent this? Would a cream be of any use?*

A.—There are worse things than a rash on the face, and the materials used and the circumstances suggested make it seem that fume-cupboard conditions are advisable. The rash on the face may be caused (or aggravated) by the exposure described; on the other hand, it might be unconnected with the work. A dermatologist's opinion would seem desirable. Barrier preparations are not, of course, intended for the treatment of skin conditions, and some types are definitely unsuitable for application to an inflamed skin. For prophylaxis, reduction to a minimum of exposure to the powdered ingredients and scrupulous cleanliness would be preferable to barrier creams.

Survival of Tubercle Bacilli

Q.—*Is a country house, with its own water supply and sanitary arrangements, which up to 2 years ago was occupied by a man aged 30 who died from pulmonary tuberculosis, fit to be taken by people with a young child? They are afraid the child might contract tuberculosis from the dust, etc., of this house. Fumigation was done by the public health authorities 2 years ago, and it has since been occupied by people with no children. How long can tubercle bacilli live in dust and dark rooms?*

A.—There should be no risk of infection from the tubercle bacillus in a house which was last occupied by a patient two years ago. There are few records of the survival of the tubercle bacillus outside the animal body for longer than two or three months. Under the most favourable conditions as regards darkness and moisture to which the bacillus is ordinarily exposed, the longest recorded period of survival is about six months, and this appears to be exceptional.

Premature Systoles

Q.—*What treatment would you advise for premature systoles? Causal factor unknown. Tobacco eliminated. Bromides have been tried.*

A.—Sepsis—oral, nasal, urinary, and genital—must be considered; also excess of tea or coffee and disturbances of gastric or gall-bladder origin. But unless the premature systoles worry the patient, treatment of them is really superfluous. Quinidine, or quinine, sometimes may abolish them, or small doses of phenobarbitone. Some authorities have found that a grain or so of digitalis leaf daily is effective. Last and not least is the careful consideration of the patient's general health. A run-down condition, overwork, overstrain, and worry may all play a part in the causation of premature systoles.

Acupuncture

Q.—*What exactly is acupuncture? Is treatment by this method ever used to-day? I once read in an old medical journal that Sir James Simpson, who thought he had discovered this treatment and obtained such wonderful results from it, believed that after his death he would be remembered more for acupuncture than for chloroform.*

A.—A brief note in Comroe's *Arthritis* mentions that acupuncture was first described about A.D. 300 in a treatise by Huang Fu. If it had been of any real value it would hardly have been lost sight of and rediscovered from time to time. It is probably simply a form of counter-irritation akin to the seton fashionable in pre-antiseptic days. Puncture with a needle conveying an electric current is sometimes advised as a method of detecting the tender trigger points in fibrositis, but otherwise the only modern method of this kind is injection of analgesic substances such as procaine into tender areas in fibrositis and traumatic conditions such as strains.

Synovitis and Synovectomy

Q.—*A male aged 30 has during the past year had several attacks of synovitis of the left knee-joint. There was no definite history of trauma, but he thought that the swelling first appeared a few days after a strenuous game of squash. After periods of splinting and firm bandaging the fluid diminished, only to recur within a few days of support being removed. Never any pain or tenderness, no limitation of movement apart from that consequent upon the presence of fluid. X-ray examination shows no abnormality, and no constitutional cause is discoverable. He has been advised to have an operation for synovectomy. What are the results of this operation, particularly with regard to range of movement usually obtained post-operatively?*

A.—Without clinical examination it is not permissible to give a diagnosis on the evidence available. On the face of it synovectomy appears to us a rather heroic measure in the circumstances as described. Synovectomy is an operation the indications for which have not clearly been laid down as yet. Two conditions of the knee-joint in particular do call for it: (*a*) chronic villous arthritis which has not responded to other measures; (*b*) synovial osteochondromatosis. In rheumatoid arthritis, where the changes are predominantly of synovial type with more or less hydrops which does not respond to conservative measures, we have another possible indication. For rheumatoid and osteo-arthritis of the ordinary types the procedure is, however, still in the experimental stage. Very few series of cases have been described, yet the present writer is convinced of the value of the procedure in well-selected examples. The ease with which movement is restored is sometimes quite remarkable, and obviously there must be considerable powers of regeneration.

The question often brought up is whether the patella should be excised. There may be an indication for this, more especially in osteo-arthritis, but one feels that to do it at the same time as synovectomy very much complicates the after-treatment. The repair of the quadriceps after patellectomy adds difficulty when one wishes to begin early movements for the synovectomy. One's impression is that synovectomy improves the whole arthritic process probably by improving vascularity. After synovectomy one expects to obtain flexion of the knee-joint at least to a right-angle, which is sufficient for ordinary use.

Treatment of Hirsutism

Q.—*Is short-wave diathermy a practicable method of treatment for hirsutism? If so, how is it carried out and with what results? I have heard of long-wave diathermy being used (as surgical diathermy). Electrolysis seems the best method.*

A.—In short-wave diathermy the electrodes must be placed some centimetres distant from the skin to avoid a burn, which would result from direct contact. It follows that as the heating effect is diffused over a varying area, treatment of this kind can have no application in the removal of superfluous hair.

Long-wave diathermy is used to remove superfluous hair, but it is open to question whether the results are superior to the old-fashioned constant-current battery, with needle attached to the *negative* pole. Scarring cannot be avoided, nor does electrolysis prevent growth of new coarse hair. Nevertheless, the patient feels and sees that something is being done. Removal with wax, as carried out in reputable establishments, gives a good temporary depilation. Only rarely can patients be persuaded to shave, although this is by far the best procedure. On no account should *x*-ray treatment be countenanced.

Removing Buried Tonsils

Q.—*In tonsillectomy by dissection, in the case of buried and very adherent tonsils, under general anaesthesia, is it safe to infiltrate the capsule by injecting a weak solution of novocain with adrenaline in order to facilitate removal?*

A.—It is quite safe unless chloroform is being administered. Incidentally, saline and weak adrenaline is as efficacious as novocain and adrenaline in reducing haemorrhage. It is, however, doubtful if any infiltration will be of much assistance.

Vulval and Pubic Boils

Q.—*A woman patient aged 57 is troubled with recurrent boils affecting chiefly the vulval and pubic regions. Can you suggest the treatment? The urine contains neither sugar nor albumin.*

A.—The treatment of boils affecting the vulval and pubic regions does not differ materially from that of boils occurring in other moist situations. If all the usual methods of treatment have been tried without success the use of penicillin is recommended. This should be applied as a spray, a solution containing 1,000 Oxford units per c.cm. being most likely to be effective; if a fine spray is used very small quantities are required. Needless to say it should be determined first whether the infecting organism is penicillin-sensitive. If penicillin is not available, local applications of sulphonamide powder or cream may be tried, but should not be used for more than a few days for fear of sensitizing the patient.

Allergy to Alkaloids

Q.—*A pharmaceutical chemist suffers from asthmatic attacks when engaged on preparation of hypodermic tablets of morphine, atropine, and heroin. Patch tests and intradermal injections of minute quantities of these drugs produce large wheals. Do alkaloids cause the attacks, or can they be attributed to an excipient? Should these drugs be avoided in a future illness?*

A.—Dermatitis has been described from contact with opium and belladonna and their alkaloids, and rashes sometimes occur after ingestion of these drugs. It is therefore probable that the asthma in this patient is the result of inhalation of the powdered alkaloids. The mechanism in these and other drug allergies is a combination of the drug with body protein to form an allergen to which the individual becomes sensitized, and it is therefore probable that an allergic reaction would occur if the drugs were given by mouth or parenterally. It is also probable that the patient would react unfavourably to any of the opium or belladonna alkaloids. It would nevertheless be desirable to carry out tests with the excipient to exclude the possibility that this is the harmful substance. Patients can often be desensitized to drugs to which they are sensitive, but this may not be practicable here owing to the pharmacological actions of the alkaloids.

Treatment of Menopausal Flushes

Q.—*A woman aged 42 is very inconvenienced by hot flushes, which began 18 months ago when menstrual periods became irregular. They were completely cured by hexoestrol 2 mg. daily, and periods started again and were normal for a few months. Periods ceased again (hexoestrol had been reduced) and flushes became marked. Hexoestrol 3 mg. given daily. Flushes better and had normal period, but flushes started intensely during this period and have continued since. She is a stable type, not neurotic, but the flushes are unpleasant and tiring. Her weight is 12 st. 4 lb., slightly increasing. Suggestions for treatment would be welcomed.*

A.—The fact that the flushes initially responded to oestrogen is suggestive that they are a climacteric manifestation. That they no longer respond is probably because the dose employed has been heavy and the treatment prolonged, so the patient has become resistant to it. This being the case, oestrogen therapy should be abandoned—at any rate for the time being—and instead thyroid should be tried, beginning with 1 gr. daily and gradually increasing the dose, short of producing toxic symptoms. Calcium in large doses (45 gr. daily), and synthetic vitamin E (3 mg. b.i.d.) might also be helpful. Although the woman is of stable type, general measures, sedatives, reassurance, and protection from nervous and physical strain remain important in treatment. An attempt to reduce the patient's weight by dieting should also be made.

If after 4 to 6 months the flushes remain troublesome, oestrogen therapy might be tried again, but the dose should be much smaller—insufficient to produce further uterine bleeding, and just sufficient to reduce the number of flushes and not to abolish them. Oestrone, or one of its esters, 0.1 to 0.3 mg. t.d.s. by mouth, should be adequate, and after 2 or 3 weeks' treatment at this level the dose should be *gradually* reduced week by week, and discontinued within 2 to 3 months.

Adder-bites

Q.—*In certain parts of the Scottish Highlands during the summer numerous adders are to be found, and occasionally adder-bites give rise to serious emergencies. What is the up-to-date treatment of the condition, "first-aid" and "long-term"? Is antivenom readily obtainable? Is it stable, and will it keep "in stock"?*

A.—The only poisonous snake in Great Britain is the adder or common viper (*V. berus*), which is more frequently met with in the northern parts of the island. Though the venom is poisonous its bite is not very dangerous to adults, yet with children there is more serious danger. A fatal result is rare. The venom of the viper contains haemorrhagin—a proteolytic poison which causes great local swelling and may lead to intravascular coagulation if the poison gets into the blood stream. There is also a small proportion of a toxin which affects the nervous system. The symptoms which result from the bite come on within a few minutes, and consist of swelling round the bitten part, and later collapse and peripheral circulatory failure if the venom enters the general circulation.

The immediate treatment is to prevent the poison getting into the general vascular system. This is achieved by the immediate application of a tourniquet tied on the limb (generally the leg) proximal to the bite. The tourniquet must not be left on for more than half an hour without temporary relaxation. Meanwhile an incision should be made at the bitten area and an attempt made to suck out the poison. Preferably this should be done by mechanical means, but it may be necessary to use the mouth when nothing else is at hand. Some authorities state that the injection of a few cubic centimetres of a 1% solution of potassium permanganate into and around the wound will destroy all the poison not yet absorbed. If general symptoms supervene restorative measures must be adopted—e.g., warmth, the administration of fluids (tea and coffee) by the mouth, and in extreme cases blood transfusion. The administration of strychnine and morphine is forbidden, for these drugs make matters worse; nor should alcohol be given if an anti-serum is to be administered.

Antivenom is not readily obtainable in this country, for it is not made in any of our laboratories. It can be obtained from India, from at least one place on the Continent, and from America. Since the serum is sufficiently stable and will keep for a year or more it could be kept in stock. When available the serum is injected into the subcutaneous tissue of the lateral abdominal wall. Doses of 10, 20, or 30 c.cm. may be necessary.

Action of D.D.T.

Q.—*In what way does D.D.T. prove lethal to pediculi, flies, cockroaches, etc.?*

A.—D.D.T. is a contact poison: that is to say, contact with the dry powder or with drops of a solution of D.D.T. is fatal to most types of insect. The lethal dose is much lower than that of any of the usual synthetic insecticides. Its action is rather slow, so that an affected insect may not die for several hours, but in the meantime it will exhibit characteristic symptoms (continuous unco-ordinated movement). The speed of kill varies with different insects: the susceptible mosquitoes and flies are usually killed in a matter of minutes, pediculi live for several hours, while bugs and roaches, which are rather resistant, may survive a day or two after contact.

Renal Glycosuria

Q.—*A young man of about 25 suffers from intermittent glycosuria. A glucose-tolerance test done with 50 g. glucose orally gave the following result: blood sugar before glucose 100 mg. per 100 c.cm.; 1/2 an hour after glucose, 120 mg.; 1 hour after glucose, 110 mg.; 1½ hours after glucose, 100 mg.; 2 hours after glucose, 80 mg. The corresponding urine sugar values were nil, trace, 0.2%, 0.1%, nil. No acetone bodies were detected in the urine. Does this condition require treatment? If not, is it a disqualification for Government service, civil or military? Will he be accepted by life insurance companies as a first-class life?*

A.—The sugar tolerance is normal in this patient, since the fasting value of the blood sugar is 100 mg. per 100 c.cm. blood, and after 50 grammes of glucose the blood sugar does not rise above 120 mg. per 100 c.cm. and has returned to 80 mg. after two hours. The top level of the blood-sugar curve, if it is venous blood, should not exceed 150 mg., and if it is capillary blood 180 mg. The presence of glycosuria shows that the threshold of the kidney is set at a level which is considerably lower than the normal, and is probably about 100 mg. per 100 c.cm. blood. This condition of renal glycosuria does not require any treatment at all. It should not be a disqualification for civil or military service; though it is possible that the military authorities might regard it with suspicion. These patients are accepted by most of the life insurance companies as first-class lives.

The Anamnestic Reaction

Q.—*What is the anamnestic reaction, and what is its significance?*

A.—The anamnestic reaction is the reappearance in the blood of an antibody produced in response to previous infection on inoculation, or an increase in its quantity, consequent on some other stimulus. A commonly observed example is an increase in titre of agglutinin for a member of the enteric group during the course of another possibly quite unrelated infection. This complicates the diagnosis of enteric fever by means of the agglutination test in persons who have had T.A.B. vaccine. Fortunately, the anamnestic reaction involves H (flagellar) agglutinins only; a rising O agglutinin titre is therefore significant of actual infection.

How is Milk Dried?

Q.—*I understand that there are different processes for drying milk. What are these processes? How do they affect the chemical or physical constitution of the reconstituted milk? Can you say which methods are used by well-known makers? What is National Dried Milk, and by whom is it made?*

A.—The processes in general use for the drying of milk are of two types: the roller (drum or film) processes, and the spray (or atomizer) processes. In the roller processes the milk is distributed as a film on the surface of revolving metal rollers, or drums, which are heated internally by steam. The film of milk dries to form an extremely thin solid sheet which is removed from the rollers by a stationary knife-edged scraper and sieved to a powder of the desired fineness of grain. In some roller processes the milk is pre-condensed in a vacuum-pan or continuous-flow evaporator before application to the rollers. The rollers may work singly or in pairs; in the latter case the milk is fed into the trough between two closely set rollers rotating towards each other. Roller-drying systems may be divided into two classes: those working at atmospheric pressure at high temperatures, and those working *in vacuo* at lower temperatures. In the spray processes the milk, usually pre-condensed to several times its initial solids content, is reduced to an exceedingly fine spray or mist in the presence of a current of heated air. The minute droplets of liquid expose a very large surface to the hot air, and evaporation of their moisture is virtually instantaneous. The droplets become small particles of powder which fall to the bottom of the drying chamber. There are various methods of obtaining the necessary fine spray, and various designs of drying chamber.

As a result of their different methods of manufacture, the roller- and spray-dried milk powders differ in their physical structure in the dry state and in their properties on reconstitution. Particles of roller powder are solid and granular and of irregular shape (mainly in the form of thin flakes); they are usually ground to pass a sieve of 0.02 in. mesh. In the whole-milk product the fat is present in relatively large masses, which when the powder is reconstituted rapidly run together and rise to form an upper layer. Particles of spray powder are spherical with an enclosed air bubble, and usually about 0.002 in. in diameter. They are individually light and fluffy, but in the bulk pack more closely than the roller type. The fat is present as very small globules, which remain dispersed on reconstitution.

The two types of powder differ markedly in "solubility"—that is, in the extent to which, when mixed with the appropriate quantity of water, they simulate the characteristics of fresh milk by the individual constituents resuming their natural states of true or colloidal solution or emulsion. In roller-drying at atmospheric pressure the film of milk reaches a high temperature and dries fairly slowly. Solubility is impaired, and is usually about 75 to 85% in cold water and 80 to 95% in hot water. In spray-drying the extremely rapid evaporation maintains the temperature of the milk particles at a very low figure, and good spray powders are practically completely soluble in cold water. Roller-drying *in vacuo* yields a powder approaching the spray type in solubility, but is apparently not carried out in this country. The insoluble matter of the powders is largely protein, with a little mineral matter. Subjection of the milk to high temperatures causes denaturation of the casein and soluble proteins, and these flocculate and lose their power of fine colloidal dispersion. The digestibility of both types of powder is very high; reconstituted roller powder yields a softer curd than fresh milk or reconstituted unmodified spray powder.

Spray-dried and high-quality roller-dried milk powder retain, on reconstitution, the nutritive value of the original raw milk to a remarkable extent, but the processing does cause some loss. Spray-dried milk loses about 20% of its vitamin C and 10% of its vitamin B_1. The biological value of its protein is reduced by not more than 5%. High-quality roller-dried milk loses about 30% of its vitamin C and 15% of its vitamin B_1; the deterioration of the proteins is greater than in the spray type. The availability of the other constituents—including vitamin A, vitamin D, riboflavin, carotene, and the minerals—is not significantly affected by either process.

Most of the milk-powder made by our well-known firms is roller-dried. It is cheaper to produce, and under ordinary packaging and storage conditions roller-dried powders containing fat—that is, the full-cream and part-cream milk powders—keep in a palatable condition longer than the corresponding spray-dried products. Recent developments in the production and storage of spray-dried whole-milk powder of long-keeping quality may, however, encourage its manufacture.

National dried milk is roller-dried in two varieties—a straight full-cream powder, with no addition, having the usual fat content of 26 to 27%; and a "half-cream" powder with a fat content of 16.5%. It is made, under official wartime enactment, by various firms in this country.

INCOME TAX

Partner Acquires Whole Practice

V. acquired the other partner's share in the practice, including the former partner's house. Can V. now claim to deduct for income-tax purposes (*a*) the cost of removal to the newly acquired premises, (*b*) the £31 paid to his former landlord for dilapidations, and (*c*) the payments made for the furniture and fittings taken over from the former partner?

⁂ The matter is not free from doubt, the expenses being in the main a matter between the partners rather than between the practice and the outside world. On the whole, however, and assuming that for, say, the first year under the new arrangement the practice is carried on as a "sole" practice, our opinion is: (*a*) and (*b*) These expenses can be deducted in so far as they relate to the professional as distinct from the private purposes; some reasonable proportion should be claimed. (*c*) Yes, but subject to two limitations. First, the amounts received for the corresponding fixtures, etc., sold from the former premises must be deducted from the total cost; and, secondly, a further deduction must be made in respect of any improvement secured by the transaction—improvement, being a "capital" affair, does not carry an income-tax claim to deduction.

LETTERS, NOTES, ETC.

Treatment of Intractable Eczema

Dr. P. KIRWAN (Northampton) writes: Your readers may be interested in this account of a cure of a particularly intractable case of infantile eczema. The case was one of about 5 months' standing in a female child of 2. The child had attended at hospital, and various treatments had been given, but all to no avail. When first seen by me the condition had spread all over the face and neck and was patchy on the scalp. It had reached the encrusted and weeping stage with many follicular pustules and bilateral blepharitis. The child was in great distress and had, naturally, been scratching. The treatment was as follows: To prevent scratching the arms were covered in cotton-wool and encased in stiff corrugated cardboard. Strict instructions were given that no soap or water be used for cleaning the affected parts. The crusts and scales were removed by applying a starch poultice, and the following ointment was applied twice daily:

Hydrarg. ammon.	gr. x
Liq. picis carb.	ʒj
Liq. plumbi subacetatis	ʒss
Vaselini	ʒij
Adipis lanae hydrosi	ad ℥j

Combined with this, a mixture was prescribed containing arsenic, 3 minims to the teaspoonful dose t.i.d. Tabs. "adalin" 1 nightly were given to ensure sleep. Frequent visits were made to see that instructions were being carried out, and it is satisfactory to record that this long-standing condition was completely cleared up in 3 weeks.

Physiology and Psychology of Craving

Dr. H. C. BROADHURST (Hounslow) writes: Your psychologist, in answer to a query on this subject (June 2, p. 793), states that when the body has need of some particular food, it feels the need for it although it has no knowledge of what it needs. He instances the hypoglycaemic child who craves for sugar. But what child does *not* crave for sugar? And does the rachitic child crave cod-liver oil or the anaemic child spinach or liver? Obviously not. Hunger is instinctive, but while we naturally prefer a mixed and tasty diet to one which is monotonous and unpalatable, we have not in fact an instinctive liking for the right *kind* of food. Hence the need for education in this matter. I doubt if piglets rush to eat earth because they need the iron in it. Rats deprived of vitamin B possess no instinct which prompts them to select food containing this vitamin when a variety of foods is offered to them. It is true that after experience rats will choose the appropriate food, but this is the result of education and not of instinct.

Sterilizing Needles, etc.

Dr. W. F. COOPER (Kingston-on-Thames) writes: You describe sterilization of needles. I find that few men know of the tip that urea melts at 132° C.; so that needles (I also sterilize gauze, etc., in small tins) can be wrapped in paper, put in the oven near some urea, and heated until the urea melts, then the oven allowed to cool. Another useful tip is that paper starts to go brown, singes, at about 150° C. Sugar starts to become caramel at about that temperature, so a dodge is to add a crystal to oil in a spoon and heat over a flame until the sugar goes brown. Amyl alcohol is not nice stuff, but it boils at about 130° C. and can be washed out by alcohol and then water. Hexamine tablets burn with a smokeless flame and are useful to carry in one's case. You do not mention the tip of running a needle into a cork, at the correct angle, and rubbing down both cork and needle. One should use a fine stone, not carborundum.

Apparatus for Caudal Analgesia

Mr. J. H. PEEL and Dr. A. H. GALLEY, whose letter appeared on June 9 (p. 821), write to say that they are very short of apparatus for caudal analgesia, and it has come to their notice that numbers of complete outfits are arriving in this country and are included in American Red Cross parcels. They ask any practitioners who come into possession of these outfits to forward them if not wanted by themselves. "Either 86, Harley Street, London, W.1, or King's College Hospital, London, S.E.5, would find us, and we would be very willing to refund postage; as you know, Red Cross material must not be sold."

Journals and Books for Italy

Major W. MACKENZIE, R.A.M.C., writes to say that there is a great need in Italy for British medical publications of any kind. If any reader has periodicals or books to spare, and would address them to Major MacKenzie, c/o the *British Medical Journal*, we would forward them to him for distribution.

SOME NEW DEVELOPMENTS IN THE MORPHOPHYSIOLOGY OF THE CEREBRAL CORTEX

BY

Prof. S. SARKISOV, M.D.

The study of the mechanism of the physiological and pathophysiological processes of the brain has for a long time occupied the attention of investigators. The work of I. P. Pavlov on conditioned reflexes has opened new ways to the understanding of the activities of the brain up to the most complicated ones—i.e., the highest nervous activities. There is no need to stress the importance of these experimental investigations, which furnish us with new ideas and methods for the better understanding of the cerebral processes, both normal and pathological, of man. A few examples of the work done will illustrate the position.

M. K. Petrova, one of the oldest pupils of Pavlov, succeeded in establishing in different dogs different types of nervous system with the precise characteristics of the various breeds. Petrova has furthermore ascertained that by inducing conditioned reflexes it is possible to produce experimentally in dogs nervous conditions which are characteristic of typical forms of neurosis. It is important to note, too, that she has ascertained that by the administration of a special dosage of bromine this experimentally produced neurosis can be completely cured.

Very interesting from the point of view of the influence of the cerebral cortex on the pathology of the organism are the experiments on conditioned reflexes in combination with the application of camphor. In the laboratories of Pavlov one of his pupils, Dolin, combined the use of the conditioning stimulant with the introduction into the organism of the dog of camphor, which, as is well known, causes convulsive epileptic fits. Having established the conditioned reflex through the introduction of camphor, Dolin succeeded, solely by means of the conditioning stimulant, without the introduction of camphor, in causing epileptic fits in the dog.

The investigations into the problem of the influence of the cerebral cortex upon the inner organs are, for medicine, in the broadest sense of the word, of particular importance. While up till now we have been able to speak only *a priori* of the influence of the " psyche " on somatic processes, the experimental investigations of K. M. Bukow and his pupils, using the methods of conditioned reflexes, have revealed definite physiological laws and the interdependence of the cerebral cortex and the inner organs—the heart, stomach, spleen, liver, urogenital organs, etc. These investigations show how, by causing certain conditioned reflexes in dogs, one can influence and alter the action of such organs as the liver, the kidneys, and the stomach. On the other hand, by a series of experiments, changes in the highest nervous activities of an animal, dependent on the condition of the inner organs, have been established. These experiments have shown the influence on the cerebral cortex of the impulses originating from the inner organs—in other words, the place which the most complex inner world of an animal has in its physiological behaviour has been established.

In these experiments it was found that, in causing conditioned reflexes or conditioned reflexive activity in an animal, new " temporary connexions " between the various sections of the central nervous system and the various organs and tissues of the organism are apparently created.

These investigations, in further developing the teaching of Pavlov on conditioned reflexes, have made it necessary to deal with the question of the morphophysiological nature of these " temporary connexions " formed in the complicated processes of the brain. Knowledge of the mechanism of these processes and their morphophysiological relations would offer new possibilities for the identification of pathological symptoms in the brain.

Recent Electro-physiological Investigations

Of great importance for this research work are the recent electro-physiological investigations, particularly of the bio-electrical phenomena of the brain, and also the new data on the finest structural features of the cerebral cortex. Bio-electrical investigations (electro-encephalograms)—carried out in various laboratories of the Soviet Union by Sarkisov, Livanov, Russinov, and Steinberg; in England by Adrian, Matthews, Walter, Ultridge, and others; and in America by Lenox, Gibbs, Davis, and others—have opened up fresh possibilities of a dynamic conception of the delicate mechanism involved in brain activity.

The numerous investigations of the last 10 to 15 years have considerably enriched our knowledge of the electro-physiological mechanism of the various sections of the central and peripheral nervous system in both the normal and the pathological state. We have now definite conceptions of the chief characteristic peculiarities of the bio-electrical current curves of the cerebral cortex, of its various sections, of the finest laminae of the cortex, of the post-cortical formations, of the peripheral nervous system, and so on. A series of investigations have also been made on bio-currents in the state of waking, sleeping, hypnosis, and so on.

Very interesting are the investigations into the bio-electrical manifestations of the brain under different influences. We were able to establish, for instance, the laws governing the variations in these manifestations under the influence of various narcotic substances—e.g., strychnine, morphine, and others (Sarkisov). It is important to note, for instance, the following fact. As we know, morphine has a depressing effect on the central nervous system. Yet our electro-encephalograms have shown that it acts differently on each region of the cerebral cortex, and that in the different stages of narcosis the potentials of the various sections of the cortex and the post-cortex are dissimilar.

Our investigations, and those of others, have shown numerous changes of the normal brain potentials in cases of mental disease—e.g., epilepsy, schizophrenia, manic-depressive conditions, and so on—and also as a result of various changes in metabolism. Of great importance also is the study of the bio-electrical manifestations in the case of organic diseases of the brain. Characteristic alterations of the ordinary encephalogram occur, for instance, in cases of tumours of the brain. Of considerable and practical interest, in this respect, are the investigations of Grey Walter, who has suggested a novel method of using bio-currents for ascertaining the seat of disease in a case of brain tumour. Our investigations of the bio-electrical phenomena in the presence of artificially caused tumours of the brain in animals have produced curious results. It was found that the bio-electrical phenomena are directly dependent on the seat and also on the character or nature of the tumour. We have produced tumours in the brain of rabbits experimentally, and have carried out series of investigations on these animals by means of electro-encephalograms. The tumours were muscular, "paraffinous," and "cancerous."

These investigations (Sarkisov and Penzik—published in 1940) revealed characteristic slow vibrations of the bio-electric potentials near the tumour. We noticed alterations of a somewhat different character at a considerable distance from the tumour, and it is particularly necessary to emphasize that the bio-currents of the brain vary according to the kind of tumour.

Fig. 1 shows an electro-encephalogram of a tumorous human brain with characteristically slow vibrations of 4 to 5 per second, instead of 10 to 12 vibrations in the normal state.

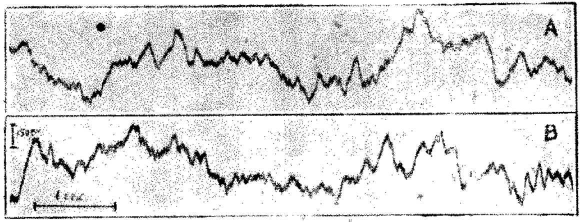

FIG. 1.—An electro-encephalogram of a tumorous human brain, 13/10/43. A, left temporal; B, right temporal.

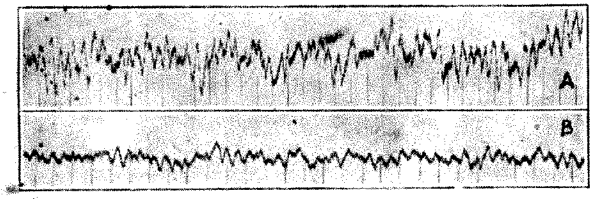

FIG. 2.—Same brain as Fig. 1. A, left occipital; B, right occipital. Recording, 30/10/43; operation, 22/11/43. Follicular abscess in right parietal area. Restricted injury of the cortex and of the white substance of the upper temporal area. Time recording, 0.2 sec.

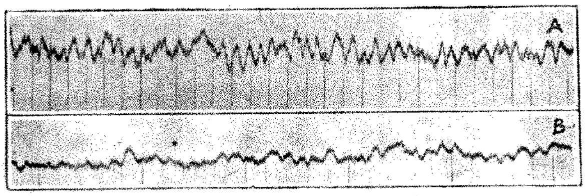

FIG. 3.—Same brain as Figs. 1 and 2. A, left central; B, right central. Time recording, 0.2 sec.

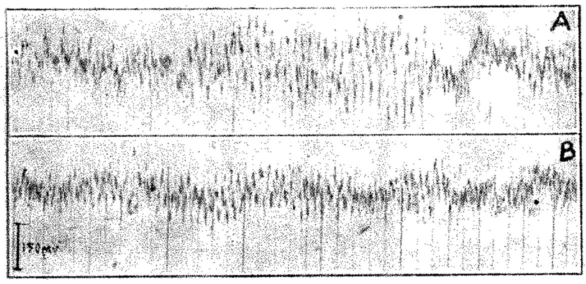

FIG. 4.—A, left occipital; B, right occipital. Deep injury of the left premotor region reaching the subcortical ganglia, with a metal fragment in the left frontal zone. Cicatrization not complicated by the purulent process. Time recording, 0.2 sec.

In our laboratories, Russinov, Livanov, Preobrashenskaya, and Lurya have during the war done a considerable number of electro-encephalograms (more than 1,300) in cases of various forms of cranium-brain wounds, and particularly of abscesses of the brain. The curves in Fig. 2 characterize the bio-electrical currents of the occipital regions of the brain in cases of various diseases of the parietal area. In Fig. 3 the curves depict the variations in the bio-electrical currents of the central region (right and left) of the same brain. Fig. 4 shows the curves of the right and left occipital regions of the injured cranium. The deep wound is in the left premotor region (reaching to the subcortical ganglia, with a metallic fragment), and in the left frontal region with a cicatrix (without abscess).

These examples should suffice to prove that the electro-encephalograms represent the separate nervous processes of the tissue of the brain in both normal and pathological states. However, it is necessary to emphasize that in each single case much in the electro-encephalogram is as yet obscure—that is, not accessible to analysis in the light of our physiological knowledge. Still, the data of the electro-encephalograms undoubtedly aid the examination of the various aspects of the complex brain processes. By means of the encephalogram we are now able, in a considerable percentage of cases, to pronounce on the character and periods of epilepsy, on tumours and abscesses, on the seat of a disease; and we can speak of a disease in the sense of its being local, and so on.

I have no space here to deal with another aspect of the electro-encephalographic investigation—the functions of the nervous tissue, central and peripheral, the laws governing the processes of excitation and inhibition, and other questions. Much has been done in this field in the Cambridge laboratories (Adrian) and in the Moscow Brain Institute (Livanov), and by others.

Physiology of the Brain

In connexion with our new ideas on the physiology of the most differentiated nervous activity and on the physiology and pathology of the cerebral cortex, our knowledge of the minute morphological organizations and connexions of the cortex is also broadening. We have now considerable knowledge of the brain, and especially of the cortical formations and the various architectonic cellular structures of the most highly organized matter of that organ. At the Moscow Brain Institute during the last 15 to 20 years specialized investigations in the phylogenesis (pertaining to a species) and ontogenesis (individual development) of the brain, and particularly of the cerebral cortex, have considerably extended our knowledge of its complex organization. Specific laws have been established governing the formation of the minute architectonic structures of the cortex and the cerebrum as a whole, in the various stages of their phylogenetic and ontogenetic development. The results of these investigations have been publishd in the form of separate works and monographs by the research workers at the Moscow Brain Institute—Philimonoff, Sarkisov, Kolonova, Blinkov, Preobrashenskaya, and others.

In emphasizing these achievements of modern neurology it may be said that our conceptions of the architectonic features of the cerebral cortex do not suffice to reveal the fundamental morphophysiological mechanism of the cortical function. In order to extend further our knowledge of the morphophysiological mechanism of the functions of the brain it is necessary to study the multiformity of the cellular architecture together with the picture of the elaborate and complex intercellular connexions and their dynamics.

Structure of the Cerebral Cortex

The methods of architectonic investigation have been of great use in establishing the general features of the structure of the cerebral cortex, its division into separate areas and regions according to the character of the various cellular and fibroid laminae, and so on. These investigations play a particular part in solving one of the fundamental problems of modern neurology—i.e., the problem of localization. The data obtained in this way are the basis for further advancement in the study of the brain. It will be necessary, however, to ascertain how the formation of the neurons of the cortex in their entirety proceeds—i.e., to trace the development of the different types of neural cells of the cortex with all their appendices; that is, the dendrites and their axons. Furthermore, it is necessary to discover how in the process of development the connexions between the various groups of neurons establish themselves inside the individual cortical formations, as well as between the various cortical regions. What I have in mind is the significance of the most delicate connexions—i.e., the synapses in the cerebral cortex. The treatment of this question is indispensable to the understanding of the intimate physiological and pathological processes of the brain.

It is well known that the method of Golgi provides the possibility for this study. It is particularly necessary to emphasize that up till now the finest connexions between the neurons in the cortex, as distinct from the synapses of the peripheral nervous system and, to a certain degree, of the lower section of the central (cerebrospinal) system, have been studied quite inadequately, if one leaves out of account the well-known work of Ramón y Cajal and others. This is due, in the first place, to the enormous difficulties arising in the study of the synaptic mechanism, especially in the cortex—as the most complicated part of the cerebral nervous system. These difficulties arise particularly in the study of the cerebral cortex of an adult. Therefore it should be expedient to study, by the method of Golgi, the cerebral cortex in ontogenesis, when the intercellular connexions and their structural features are comparatively simple and more easily accessible.

So far as we know, the study of the ontogenetic development of the cerebral cortex by Golgi's method has not yet been fully carried out. (Cajal investigated chiefly the brain of the newborn and in the first months after birth.) The first to start these researches was Dr. G. I. Polyakov, in the Moscow Brain Institute. It is not my aim to give a full account of his investigations into the study of the functioning of the cerebral cortex. Polyakov is about to publish his results in a monograph. Still, I would like to give at least a few illustrations from his studies, so as to convey some idea of the importance of the data obtained:

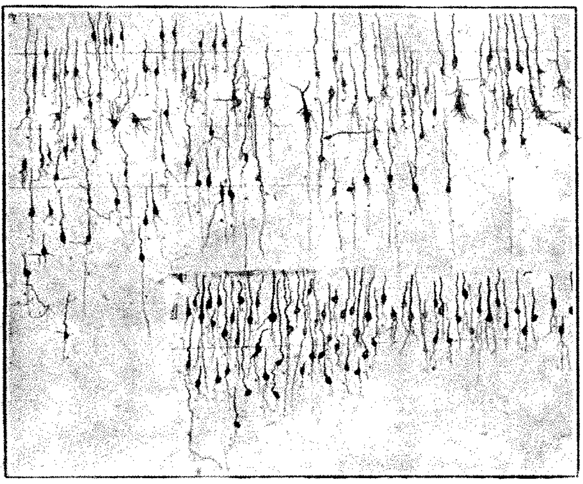

FIG. 5.—Four-lunar-months foetus. Above, formation of the precentral cortex (area 4). Below, formation of the optical cortex (area 17).

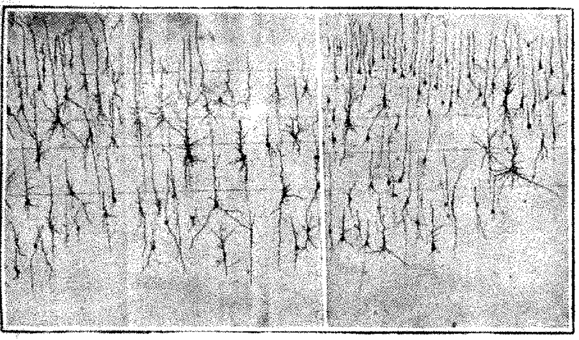

FIG. 6.—Five-and-a-half-months foetus. Left, precentral area 4; right, postcentral area 1.

Fig. 5 shows the picture of the cellular structure in an embryo of 4 lunar months, where the upper lamina of the cells has been taken from the precentral region, and the lower lamina from the optical cortex—i.e., from the occipital pole of the brain. We notice here, in the earliest stage of the organization of the cortical cellular elements of neuroblasts, an apparently similar picture of the cells and their appendix in the precentral and optical regions. Still, it is not difficult, even to the naked eye, to notice, already in this stage, the differences in the shape of the cells and the characteristics of their appendices.

Fig. 6 represents the organization of the cortical structure in an embryo of 5½ months. To the left is the cortex from the precentral region; to the right, from the postcentral region. Here the difference in the shape of the cells, and particularly in the shape of the appendices, seems even more distinct.

The next differentiation of these connexions in an embryo of 8 months is of great interest with regard to those of the cortical structure. In Figs. 7 and 8 are shown the formation of the intercellular connexions of the frontal, lower-sinciput, and postcentral regions. One notices very fine cellular appendices of extraordinary multiformity and peculiarity in the three regions of the cortex in the embryo of 8 months; in the frontal region (precentral and motorial), strongly developed cells with significant vertical appendices. Contrary to this, the cells in the postcentral, and especially in the lower-sinciput (associatory), region of the cortex are considerably smaller and at the same time their appendices are distinguished by greater delicacy and multiformity. And, what is most important, they are distinguished by significant appendices extending laterally—i.e., in a horizontal direction—which obviously is largely characteristic of the receptive type of cortex. These fine neuron formations are obviously best distinguishable in the last month of uterine gestation.

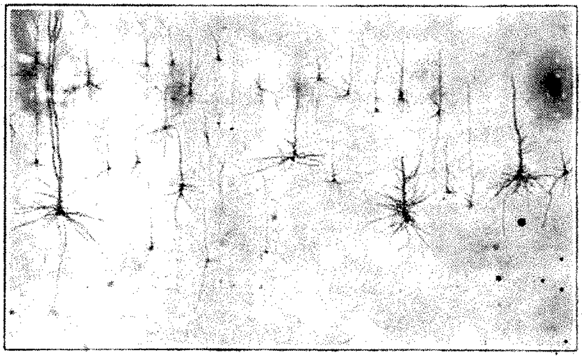

FIG. 7.—Eight-lunar-months foetus. Precentral agranular cortex (area 4).

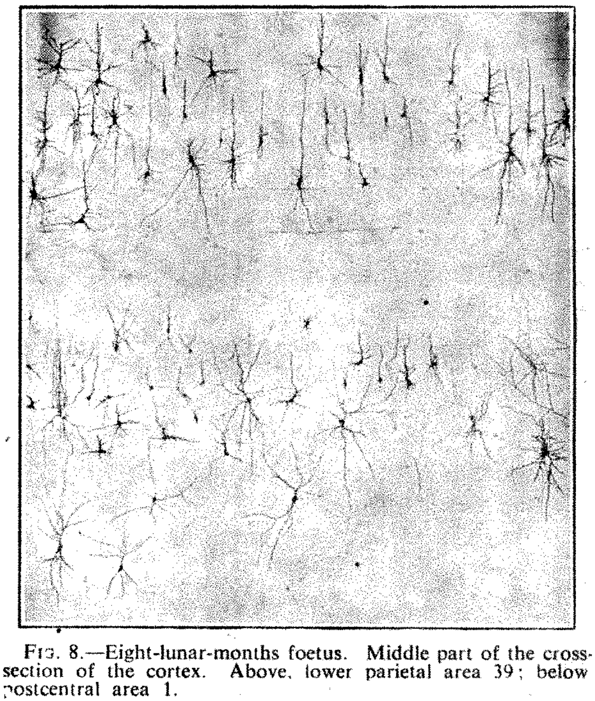

FIG. 8.—Eight-lunar-months foetus. Middle part of the cross-section of the cortex. Above, lower parietal area 39; below postcentral area 1.

Conclusion

I shall not dwell here on a full description of all the details of this amazingly diverse picture of the cellular structures and their appendices. They will be dealt with separately by Dr. Polyakov. Particularly important are the examination and the establishment of these structures in the adult. The examples given above convey some idea of the new data concerning the finest and most complicated structural features of the cerebral cortex. There is no need to prove that on these data the processes of the cerebral cortex in the normal and pathological state are based. Can one doubt the intimate physiological part which these minute intercellular formations play? Can one doubt that in various pathological affections of the brain as a whole, and of the cerebral cortex in particular, these delicate intercellular structures are the first to be exposed to disease, being the most vulnerable? Of special interest are these data from the point of view of pathological changes of the brain in the so-called "functional diseases" of the nervous system. Obviously, in various "functional diseases," and also in many cases of psychosis, where we are not in a position to identify definite changes in cellular structure, one must assume first of all an affection of these intercellular connexions. The examination of these amazingly fine and diverse structural formations of the cortex presents us with more problems, the resolving of which is one of the chief tasks of modern neurology and neurophysiology. The work of the research staff of the Moscow Brain Institute is dedicated to the study of these questions.

Summary

The classical method of Pavlov in conditioned reflexes enriches considerably our knowledge and understanding of the part which the cortex plays in the most differentiated nervous activity and of the connexion of the cortex with the functions of the inner organs. The novel method of bio-electrical currents, and the exploration of the finest morphological structures of the cortex and its intercellular connexions, open new ways and opportunities for establishing the laws governing the fundamental morphophysiological mechanism of the complicated activity of the cerebral cortex.

DERMATITIS FROM WEARING ARMY SPECTACLES

BY

W. O. G. TAYLOR, M.B., Ch.B., D.O.M.S.

Major, R.A.M.C.; Ophthalmic Specialist

AND

A. G. FERGUSSON, M.D., F.R.F.P.S.

Major, R.A.M.C.; Specialist in Dermatology

WITH

SPECIAL REPORT BY

W. R. G. ATKINS

Lieut., R.A.M.C.; R.A.M. College

Although dermatitis due to the dye in artificial-shell glasses is fairly well known (Thistlethwaite, 1943; Gray, 1943) there has been little mention of a similar dermatitis resulting from the wearing of spectacles with metal frames, since its inconvenience is easily avoided under normal civilian conditions. Between December, 1941, and March, 1942, six cases of such a condition were seen by us at a military clinic in Scotland.

The Army spectacle frames (Mk. III) are made of "nickel silver" plated with nickel. Nickel silver has the advantage of useful corrosion-resisting properties; it is an alloy of nickel, copper, and zinc in the following proportions:

Part of Frame	Nickel	Copper	Zinc
Bridge	25%	60%–65%	10%–15%
End-pieces	25%	60%–65%	10%–15%
Cables	12%	60%–65%	23%–28%
Eye-wires	12%	60%–65%	23%–28%
Butts	10%	60%–65%	25%–30%

After manufacture the frames are given a solid nickel plating. It will be noted that the percentage of copper does not vary: the physical properties of ductility, hardness, etc., depend on the relative proportions of nickel and zinc. Common impurities—sulphur, lead, iron, and mercury—are all harmful in the alloy, and to avoid them the raw materials used in the casting consist only of pure nickel, electrolytic copper, and electrolytic zinc. Samples of each of these substances as well as the alloy, and alloy finally plated with nickel, were supplied by the metallurgists for the purpose of a patch test.

The physical state of the metal is of some interest. In the first place the raw material used is dead soft and therefore in an amorphous state. In the case of the eye-wires this condition is not greatly changed, as the only process is that of rolling and cutting. However, in the case of all other components, striking and reducing operations are carried out, and the metal must therefore be in a more or less crystalline state as a result.

A study of dermatological literature shows that dermatitis is not uncommon in the nickel industry (Blaschko, 1889; Landsteiner, 1924; Bulmer and Mackenzie, 1926; White, 1928; Jadassohn and Schaaf, 1929; Stauffer, 1931; Goldman, 1933; Stewart, 1933), but the first mention of sensitivity to spectacle frames containing nickel seems to be that of Lain (1931), followed by Fox (1933), Urbach (1935), Kristjansen (1937), and Löwenstein (1938).

Lain describes three cases of dermatitis occurring on the temples and ears of men wearing spectacles. In each case the frames were made of so-called "white gold," reported as an alloy of gold, copper, and nickel. In his first case the eruption occurred also across the bridge of the nose, but in the other two the bridge of the spectacles was of a different metal, and the eruption occurred only on the temples and ears. On his inquiry, the optical company manufacturing the glasses instituted a research in their laboratory and reported as follows:

> "The trouble seems to be due largely to nickel that is found in white gold alloy. We believe that the action is largely electrolytic; that is, an electrolytic battery action is produced when there are dissimilar metals and an acid (or in some cases an alkaline) fluid is present and in contact with these dissimilar metals. When the perspiration, which is an electrolyte, acts upon the base, metal salts are formed, and such action is more pronounced in the presence of heat. It is probably a salt of the nickel that causes the irritation, which seems to be analogous to a trouble that is present in the nickel-plating industry called commonly 'nickel itch.'"

The case quoted by Fox (1933) was sensitive to both spectacle frames and a wrist-watch made of this white gold.

Goldman in 1933 surveyed the literature up to then and added two cases (not due to the wearing of spectacles) in nickel-workers. Citing the cases of Lain and Fox, he suggests that, in spite of strong presumptive evidence, the failure to perform eliminative patch tests had not positively incriminated the nickel. Both his cases gave a history of previous allergic disturbances (urticaria and hay-fever). Both gave strong responses to patch tests with nickel but negative to the closely allied metal, cobalt, thus showing a strong specificity to the nickel. This specificity, associated with the abnormally short latent periods in his cases (2 days and 3 days) before the appearance of the intolerance, suggests that the hypersensitivity may have been gained by: (1) inherited or congenital idiosyncrasy; (2) exceptionally rapid sensitization (the normal interval is 8 to 10 days); or (3) repeated brief contact with the metal (perhaps as nickel coins or suspender buckles) without appreciable clinical manifestation—the so-called "silent sensitization." Urbach (1935) described a case of sensitivity to nickel-framed spectacles. A patch test with an Austrian schilling, which contains a large percentage of nickel, gave a positive reaction. As the schilling contains other metals, this is of course insufficient as an eliminative test

That this is not a very infrequent problem when the wearing of nickel-framed spectacles is necessary is shown by the fact that six cases were seen by us in a small area within three months and that similar cases (Bettley and Lyle, personal communication) have occurred in other parts of the country.

Case 1

Pte. H. G.; Pioneer, aged 31; single. Received glasses Jan., 1941: myopia, −9.00 dioptres. Within a month a reddish patch developed where the spectacles touched the skin. After a time wearing the glasses for 5 to 10 minutes caused recurrence after a latent period of 15 to 30 hours. Since in spite of treatment it kept recurring on resumption of the spectacles, he was referred to us.

Examination on Dec. 2 revealed vesicular eczematous dermatitis wherever the spectacles touched the skin—behind the ears, over the temples and zygoma, on cheeks eyebrows, and sides of the nose where the pads touched. There was no history of drug sensitivity or other allergic phenomena. Mild pityriasis sicca capitis was present.

Treatment.—The skin healed with calamine lotion, but only when the spectacles were left off. A patch test was performed in the interscapular area with part of the frames, and gave a marked positive reaction in 48 hours. A control patch was negative. The following expedients were then tried: (1) A new pair of glasses: skin broke down in six hours. (2) Zinc adhesive plaster applied over parts of frames in contact with skin: lesion recurred. (3) Cellulose acetate varnish painted on to frames: successfully prevented recurrence, but started to peel off within four days. (4) Cycle-tyre-valve tubing pulled over flexible ear-curls and pads, xylonite half-rings (" washers " in optical trade) clipped over rims, and jaconet covers stitched over flat sides. This final attempt was highly successful, and the covering could easily be renewed when worn out.

Further patch tests were now carried out with the elements of the alloy received from the metallurgists.

Test Patches	24 hours	48 hours	72 hours	96 hours
Pure nickel	−	−	+	++
Nickel silver alloy	−	+	++	+++
Copper	−	−	+	+
Zinc	−	−	−	−
Plaster control	−	−	−	−

The copper test, repeated 10 days later, was then negative. On March 23, 1942, the Prausnitz-Küstner reaction was carried out on Cpl. B. (a volunteer test subject), and was negative to both nickel and nickel alloy.

Case II

Gnr. A. B., aged 38, married; Army and civil occupation, clerk. At school he was unable to wear metal-framed spectacles owing to " breaking down of the skin ": no trouble with shell frames. Refractive error small, but finds glasses essential to his work as a clerk. While in France in 1939 he was provided with Mk. III spectacles. Within three days he felt an itching of the skin in contact with the frames. Soon it became reddened and moist, and began to peel. This stopped as soon as the glasses were left off. There was no history of allergic illness or skin disease. Examination on Dec. 8, 1941, revealed a condition similar to that in Case I. There was no other skin lesion. A patch test with a portion of his own spectacle frames gave a weak positive result. On discarding the glasses the skin on the face healed within seven days.

This man also had a trial of the cellulose enamel treatment to his spectacles, but it began to wear off even more quickly (24 hours), so a pair of frames were covered as in the final experiment in Case I, with equal success.

Case III

Gnr. N. H., aged 32; married. Army occupation, driver; civil occupation, machinist (costumes). Received Mk. III glasses Oct., 1941: myopia, −1.50 dioptres. The second day after wearing these the skin began to break—owing, he thought, to friction, as the glasses fitted rather tightly. Not until the next day did it become inflamed, starting with a burning pain and itching. He then left the glasses off and the skin healed after three weeks. Later, when on guard duty, he was ordered to wear them, and again the skin broke down after only two hours. There was no history of allergic disturbances, or skin disease except boils, nor was he taking drugs of any description.

On account of the abnormally wide distance across the forehead the fit of the glasses was not good. The dermatitis, distributed as above, was a vesicular eczematized condition with slight secondary infection. There was also slight pityriasis sicca capitis with comedones. The glasses were withdrawn: no treatment was given, and when he returned in 20 days the skin was quite healed. The fit was then very carefully adjusted to avoid all friction, but once more the lesion recurred after six hours. Patch tests were then carried out with portions of frames from each of three manufacturers:

Test Patches	24 hours	48 hours	72 hours	96 hours
Frames " A "	−	−	doubtful	+
„ " B "	−	−	„	+
„ " C "	−	−	„	++
Plaster control	−	−	−	−

In view of the low refractive error it was considered that this was an ideal case for fitting with " respirator wafers " (Taylor, 1944), which give correction during the wearing of the respirator. At other times he was allowed to wear shell frames.

Case IV

Cpl. R.; Pioneer, aged 37; married; civil occupation, slater. Moderate myopic astigmatism. Received Army glasses in Aug., 1941, and wore them constantly with no trouble for about three or four weeks. First noticed a soreness over the bridge of the nose; then the skin broke and began to weep. Soon the eyebrows were involved, followed by the skin over the temples and behind the ears. The fit of the glasses was always good. Treatment with ointment had no effect, and calamine lotion also failed to cure, although it kept the lesion in check. He returned to the specialist who had prescribed the glasses, and was advised to wear his shell frames and leave off the Army pair. The skin then healed within three to four weeks, using only calamine lotion.

When examined by us on Feb. 1, 1942, after wearing metal glasses again for a few days, he had pityriasis sicca capitis and also a mild seborrhoeic eczematoid condition of forehead and cheeks. Treated with skin paste, this cleared up rapidly, revealing an underlying and resistant spectacle dermatitis. The glasses were removed, and in three days the skin healed. There was no history of allergic disease, nor was he taking any drugs. He had not previously worn white-metal frames or a wrist-watch. Patch tests as in Case III.

Test Patches	24 hours	48 hours	72 hours
Frames " A "	−	−	+
„ " B "	−	−	+
„ " C "	−	−	+
Plaster control	−	−	−

A trial was made of the cellulose varnish, but within a day it was already starting to peel off, so the frames were covered as in Cases I and II. After wearing these for a month there was no recurrence.

Case V

Cpl. W. M. S., aged 26; married. Army occupation, M.O.'s clerk; civil occupation, schoolmaster. Mk. III glasses prescribed Dec. 10, 1940: low myopic astigmatism. At first, when these were worn only once a week for an hour during the gas practice period, no trouble was experienced. In May, 1941, he started to wear them constantly, and after six days the skin in contact with the frames began to discharge and the pads stuck to his nose. There was slight itching. When the spectacles were discarded the lesion cleared up in one or two days, but each time they were worn again the trouble recurred. He had not previously worn white-metal frames or a wrist-watch.

On Feb. 9, 1942, after wearing the glasses for five days, there was mild weeping and desquamation. No seborrhoea was present, and there was no history of other allergic disturbance or previous skin disease. He was not taking drugs of any sort. The skin actually healed without any treatment while under observation and while the same glasses were in occasional use, although adjusted so as to have little contact with the skin except behind the ears. Patch tests were carried out as follows:

Test Patches	24 hours	48 hours	72 hours
Frames " A "	−	doubtful	doubtful
„ " B "	−	„	„
„ " C " (nickel worn)	+	+	+
Plaster control	+	+	+

In view of these equivocal results and the behaviour of the lesion while under observation one wonders whether in the course of his Army occupation he had learned of this condition and perhaps caused an artefact. In any case, special correction did not seem necessary, and he did not return.

Case VI

Dvr. T. T., aged 32. Army glasses had been prescribed about a year previously. There was no trouble until after six months, when the skin over the bridge of the nose, around the ears, and over the temples broke down. It did not heal until he changed to his reserve pair. Thereafter it remained well until four days before we saw him. Examination on March 1, 1942, showed an eruption similar in appearance and distribution to the previous cases. Seborrhoea was well marked, and pityriasis sicca capitis and a tendency to comedo formation on the skin of the forehead were present. There was no history of skin disease or of previous allergic phenomena, nor was he taking drugs of any kind. The glasses were seen to be roughened, and the nickel plating was worn off over a large area; they were therefore withdrawn. In a week the skin had completely healed without other treatment. Patch tests were carried out.

Test Patches	48 hours	72 hours	96 hours
Nickel silver	−	+	
Alloy plated with nickel	++	++	
Zinc	−	−	−
Copper	−	−	−

The Prausnitz-Küstner test was performed, the result being negative to both the nickel silver and the plated alloy. On March 23 he was fitted with frames covered as previously described. In September he returned when the frames required renewal of the rubber tubing. There was a slight recurrence where the metal had come into contact with the skin, but otherwise he had remained perfectly well.

Discussion

These cases are clearly similar to those of Lain and Fox. What is the mechanism of this disorder? (1) It may be mechanical (artefact, roughness of metal parts, bad fit, or roughening of parts during adjustment with pliers). (2) It may be due to an ingested substance which can interact with the metal—sulphur, mercury, etc. (3) It may be an allergic phenomenon.

That our cases were not due to mechanical causes is shown by the fact that the fit was never a matter for complaint (except in Case III; and here, after great care had been taken to secure a perfect fit, the intact skin broke down within six hours). Careful observation, in addition to the various patch tests, eliminated the possibility of artefact, except perhaps in Case V.

In every case except No. II careful inquiry was made as to the taking of any drugs such as sulphur or mercury, and it appeared that none of the patients was taking even a purgative or was under treatment for syphilis.

There remains the possibility of an allergic or pseudo-allergic cause. To incriminate the spectacle frames as a cause of an allergic skin response one must inquire: (1) Can the metal become ionized under conditions of wear? (Woods, 1933; Landsteiner, 1924.) (2) Do the history and mode of onset suggest allergy? (3) Does the lesion clear promptly on removal of the frames? (4) What is the response to specific patch tests? (5) Can this specific hypersensitivity be transmitted? (Prausnitz and Küstner, 1921.)

Lain quotes a company of manufacturing opticians who, after research, stated that they believed there was an electrolytic battery action between the dissimilar metals of the alloy in the presence of perspiration and aided by body heat.

Specimens of the frames were submitted to Lieut. Atkins, who reports as follows:

> "The specimens were washed in absolute alcohol to remove traces of grease and then placed in distilled water, slightly acid as it always is, for several days. There was no trace of nickel by the most sensitive tests, and the surface remained bright. With sodium chloride in the water, between 1% and 2%, there was, however, slight reaction, so that after two or three days there was a marked pink with dimethyl glyoxine and ammonia with specimen 'C,' a definite but lesser pink with specimen 'A,' and no perceptible pink with specimen 'B.' It is possible that there would be still greater reaction if a complete frame was tested, due to one side being electronegative to the other. In this case the dermatitis might be earlier and more marked on one side. It is also obvious that this reaction requires the intermediary of sweat."

It will be noted that all the cases except II and V suffered from pityriasis sicca capitis, and all reported that they sweated very easily. The wearing of a respirator of course induces free perspiration under the rubber. In only one case was an inequality in the dermatitis noted—the worst case, No. III, in which the left side was earlier and more severely affected.

With regard to the second requirement, all these cases conform to the allergic types, with the exception of the doubtful case, No. V. Case II is the only one with a history of a previous intolerance, which explains the short latent period here. Case III also, with a brief latent period, had a breaking of the skin *before* the burning and itching, and may be explained as the mechanical effect of a bad fit which later became a true allergy, since, in the absence of mechanical irritation, the intact skin broke down in six hours. It does not seem necessary in any of these cases to appeal to the "silent sensitization" mentioned by Goldman, although the number of objects of everyday use which contain nickel is adequate—coins, badges, buttons, plumbers' fittings, parts of motor-cars, as well as the E.P.N.S. forms of tableware and cutlery.

The third requirement is fulfilled, since all cleared up promptly, only the most severe case taking more than a week to do so.

The response to specific patch tests is, as Goldman suggests, the vital test to detect the specific cause, and the results shown above strongly support the hypothesis that the nickel silver is the cause of a specific hypersensitivity. The tests were carried out with the standards laid down by J. Jadassohn and Bloch. Various tests were performed. Cases I to V were all patch-tested with a portion of the actual frames worn, and all were positive. Cases III, IV, and V were tested with portions of frames made by each of three different manufacturers. The results reveal no significant variation. Cases I and II were patch-tested with the separate elements of the alloy, and showed no reaction to the copper and zinc, but some reaction to pure nickel; there was a marked reaction to the alloy itself. The Prausnitz-Küstner reaction was tried in Cases I and VI. Both were negative. It is possible that the injected individuals did not perspire sufficiently.

Finally, a word might be said about occupational causes, but the wide variation in the civil and military occupations seems to rule this out.

Treatment

The occurrence of six cases in a short period of time from a fairly small group makes the question of treatment an important one from the military point of view. It is obvious that desensitization is too slow and uncertain a procedure for military use. The various methods employed by us have been discussed: it only remains to mention that rhodium and chromium plating proved a failure (Bettley and Lyle, personal communication, 1941).

From all points of view the most satisfactory solution was the adoption of the correcting wafer applied to the respirator eyepiece for use during gas attacks and of gold or shell frames at other times. When the refractive error is too high for satisfactory correction by a wafer the best expedient is to cover the frames in the manner prescribed for Case I. This involves only the use of easily obtained materials, and can be renewed by the soldier himself. It does not affect the gas-tightness of his respirator.

Summary of Conclusions

We conclude that dermatitis arising from the use of Army spectacles is an allergic phenomenon resulting from a prior electrolytic battery action which ionizes some of the nickel in the presence of the acid sweat and dissimilar metals, aided by the body heat.

Our acknowledgments and thanks are due to Brig. Sir Stewart Duke-Elder, K.B.E., for his interest and assistance in obtaining the cellulose varnish; to Brig. R. Cormack, O.B.E., D.M.S., E.A. Command, for permission to publish; and to Col. (now Brig.) W. K. Morrison, A.D.M.S., West Scotland Area, for permission to carry out the experimental part of the investigations.

CEREBRAL FAT EMBOLISM AFTER ELECTRICAL CONVULSION THERAPY

BY

A. MEYER, M.D.

Neuropathologist, Central Pathological Laboratory, L.C.C. Mental Health Services

AND

DONALD TEARE, M.B., M.R.C.P.

Assistant Pathologist, St. George's Hospital

Electrical convulsion treatment is rightly regarded as the safest of the shock methods available so far. Only a few fatal accidents have been reported in the literature (Alpers and Hughes, 1942; Ebaugh, Barnacle, and Neubuerger, 1943; Napier, 1944). The last-mentioned author described 5 cases, which he considers to be the only deaths in England and Wales; in none of them had a microscopical investigation of the C.N.S. been carried out. According to Alexander and Löwenbach (1944), three possible mechanisms may account for the fatal outcome. The first is direct action of the electric current upon the brain tissue through which it passes, resulting in vasoconstriction and blanching of the tissue. They demonstrated this in animal experiments, but to obtain this effect shocks were necessary which in amperage, duration of flow, and density of current far exceeded those used in electric-shock treatment in human patients. The second mechanism is excessive stimulation of the vago-vasomotor centres of the medulla, causing generalized circulatory disturbances. This mechanism becomes operative only if the electrodes are placed in too posterior a plane, allowing the current to flow through the hind-brain. It is conceivable that some of the conflicting experimental results in animals, could be explained in this way. The third group is concerned with patients whose impaired cardio-circulatory-respiratory system cannot stand up to the excessive demands imposed by a convulsion.

The present case does not fall into any of these categories. It showed pathological changes which are of some practical and theoretical interest, and for this reason its publication seems to be justified.

Case History

The patient, a man aged 53, was admitted to Springfield Hospital as a certified patient on March 31, 1944. He had recently taken 108 aspirin tablets, as he thought he was being followed by hundreds of plain-clothes detectives. His physical condition was good. He had sustained gunshot wounds at the back of the right knee during the war of 1914–18, and now complained of severe pain in this knee, with inability to straighten the leg. The local lesion did not appear to be entirely responsible for this disability, and, indeed, under sodium amytal and suggestion therapy the patient was able to walk about freely without pain. Prolonged somnifaine narcosis was given from April 30 to May 15, but no lasting improvement resulted. Psychotherapy and occupational therapy were continued until December.

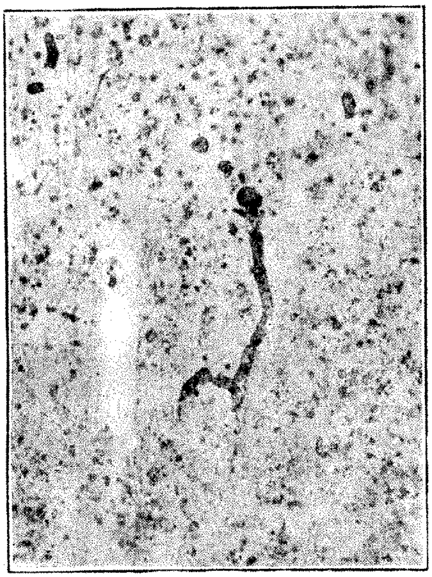

FIG. 1.—Frontal cortex. Scharlach R stain. (×130.)

At 10.10 a.m. on Dec. 5 an electric convulsion was instituted by a standard commencing strength of 120 volts alternating current for 0.3 second. After a latent period of one second a very strong fit lasting 55 seconds resulted. He made a fair recovery and was able to answer questions, but was pale and restless and complained of pain in the back. At 10.30 a.m. he collapsed and was given first 5 c.cm. and then 4 c.cm. of nikethamide. He improved and was able to take some tea at 11 a.m. He vomited the tea, and at 11.45 a.m. more nikethamide was given with intranasal oxygen and carbon dioxide. Again there was a slight improvement, but he collapsed at 12.45 p.m., and from that time remained unconscious, pale, and restless. Respiration was rapid and the pulse rapid and thready. At 3 p.m. his blood pressure had dropped from 148/90 to 110/90, and a pint of reconstituted blood serum was given slowly with 5 c.cm. of nikethamide. His condition steadily deteriorated and he died at 10.50 p.m. the same day.

Post-mortem Examination.—The body was well nourished. There were no external burns or abrasions. Two old scars were seen behind the right knee; they were superficial and not attached to deeper structures. A careful examination of the spine, ribs, pelvis, and skull failed to reveal any fracture. There was no bruising, deformity, or crepitus to suggest a fracture in any of the long bones. The meninges were congested; several small petechial haemorrhages were seen in the midbrain and in the frontal regions. Apart from congestion, which was most pronounced in the lungs, there was no significant macroscopic change in the other organs. Only the brain was sent for histological examination to the Central Pathological Laboratory.

Histological Investigation of the Brain.—Numerous blocks from all regions were examined by the usual neurohistological methods. No significant pathological changes could be demonstrated with methods which stain nerve cells, nerve fibres, and the glia. No petechial haemorrhages were seen in any of the slides, which indicates that those noticed macroscopically were only few in number. There was, however, a considerable degree of congestion of all capillaries and veins. The fat stain revealed a surprising change. As Figs. 1–3 unmistakably show, many capillaries were blocked by fat emboli. These fat emboli occurred to a varying degree in all regions of the brain, including the cerebellum. They were more frequent in the grey matter than in the white.

Discussion

The diagnosis of cerebral fat embolism is established by the histological evidence and also clinically suggested by the so-called "free interval"—although it was not entirely free of symptoms and there is some doubt whether it ended with the first collapse about 20 minutes after the convulsion or with the second final collapse about two hours later. The characteristic petechial haemorrhages of the skin were absent; in the brain only a few were encountered.

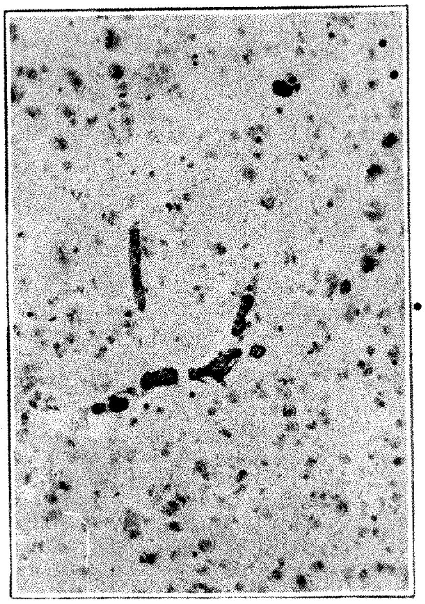

FIG. 2.—Occipital cortex. Scharlach R stain. (×130.)

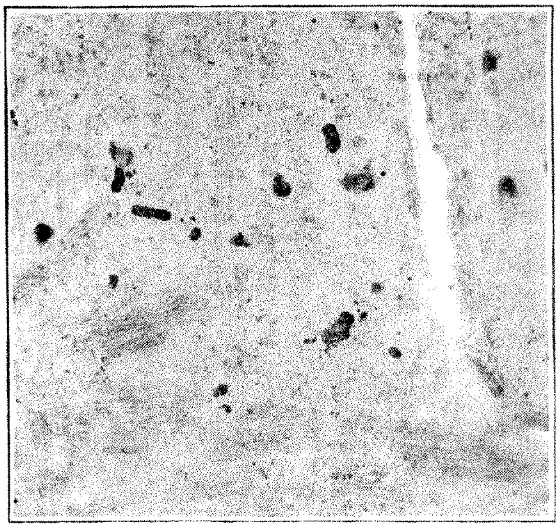

FIG. 3.—Medulla. Scharlach R stain. (×120.)

Cerebral fat embolism has not yet been described after electrical convulsion treatment. It has been found, however, by Nightingale and Meyer (1940) in a patient dying after shocks produced by triazol, and by Nielsen and Ingham (1940) after treatment with leptazol (cardiazol). In the last-mentioned case fractures of both femora were responsible, while in Nightingale and Meyer's case no fracture was noted, although a vertebral fracture could not be excluded. In the present case the patient complained of backache, but despite careful post-mortem search no fracture of the limbs, spine, or any other osseous part of the body could be detected. It is therefore necessary to consider other possible causes of fat embolism.

Apart from fractures, widely recognized causes of fat embolism are severe contusion, deep laceration of skin, severe burns, operations on adipose persons, and forceful orthopaedic manipulations (Strauss, 1933). Concussion as a causative factor has been recognized for 70 years (Robb-Smith, 1941a), and its significance has been stressed also by Silverstein and Konzelman (1940), but it should be remembered that most of the evidence is of an experimental nature (Strauss, 1933). The claim made by Robb-Smith (1941a) that blast alone may cause fat embolism has not been confirmed by subsequent authors (Zuckerman, 1941), but, if found, it should be regarded as a complication.

Convulsions and violent exertion during certain types of psychoses such as delirium tremens are occasionally mentioned as a possible cause of fat embolism (MacCallum, 1936), but the fact that fractures are more often produced by epileptic convulsions than was known in the past tends to qualify the significance of these older views. We were unable to trace any reference to this point in modern neurological treatises. One of us (A. M.) has investigated five brains from epileptics dying suddenly during or after convulsions. In four of these he failed to find fat emboli in the bodily organs, including the brain. Occasionally intravascular substances staining light pink with Sudan and usually not occupying the whole lumen of the vessels were encountered. They were also found, however, in other conditions, including carbon monoxide poisoning and tuberculous meningitis. These lipoidal substances, whatever their significance may be, are not likely to be of an embolic nature. It is possible, however, that they may have been confused with fat emboli by earlier investigators. Only in one case of death after epileptic convulsions was true fat embolism of the lung and, to a lesser degree, of the systemic circulation found. This was in a patient suffering from lipoidosis of the Hurler type (gargoylism).* The liver and spleen were enormously enlarged, and contained an abundance of fatty substances, which may have been an important facilitating factor, just as the danger of fat embolism is increased in operations performed on adipose persons.

Opinion is still divided on the role of the blood lipoids in the formation of fat emboli. The most fully substantiated instance of haemic origin appears to be alkali poisoning (Robb-Smith, 1941b), followed by either hyperlipaemia or lipoproteolysis. Macfarlane, Oakley, and Anderson (1941) were able to produce *in vitro* free fat from blood to which *Cl. welchii* toxins had been added. Winkelman (1942), surveying previous experimental evidence, seems to favour the haemic hypothesis in view of the presence of large amounts of fat in the lungs and brain following mild injury or fracture of the smaller bones of the body, which are not likely to release a supply of free fat sufficient to cause widespread embolism. It is interesting that hypercholesterolaemia occurs in a large proportion of cases submitted to electrical convulsion treatment as well as after spontaneous convulsions (Katzenelbogen, Baur, and Coyne, 1944).

At the present stage of our knowledge it is impossible to say which of the factors surveyed above has been operative in our case. Although there was no evidence of a fracture of bone or contusion or laceration of other fat deposits of the body, it must be admitted that an unobtrusive mild fracture or any other of the common sources of fat embolism might have been overlooked. So far, this case should be regarded as an exceptional complication of electrical convulsion therapy.

In reporting the above case it is not our intention to point out any increased risk associated with this form of shock treatment. It is well, however, in future post-mortem investigations of sudden and unexplained death after electrical convulsion therapy, to keep the possibility of fat embolism in mind, particularly if a fracture has been produced. One of us (D. T.) has made a previous observation of death produced by electric shock treatment: the patient was a female schizophrenic aged 42. During the first treatment a current of 130 volts, lasting 0.3 second, was given after lesser applications had failed to produce a convulsion. The fit lasted 58 seconds. After 3 hours the patient was still unconscious. At intervals until she died, 19½ hours after the fit, she almost regained consciousness. At the necropsy no injuries, burns, or fractures were found. There was acute pulmonary oedema throughout the lungs. The liver was slightly fatty, the uterus was absent, the meninges were congested, and the brain was macroscopically normal. No histological investigation was carried out.

The absence of a free interval before the onset of the terminal symptoms militates against the diagnosis of fat embolism in this case, although atypical cases have been recorded. Excessive vago-vasomotor stimulation (the second group of Alexander and Löwenbach, 1944) might be an alternative explanation.

Summary

A case has been described in which sudden death after electrical convulsion therapy was caused by cerebral fat embolism.

Neither a fracture nor any of the other recognized causes of fat embolism were found post mortem. Other possible causes of fat embolism have been considered, but no final decision is justified at the present moment. The problem calls for special clinical and pathological attention in similar cases.

We wish to thank Mr. J. W. Hulme, Assistant Deputy Coroner, Southern District, County of London, and Mr. H. G. Broadbridge, Coroner for the Western District of Middlesex, for permission to publish the case. We are also indebted to Dr. J. H. Ewen, medical superintendent, Springfield Hospital, and Dr. C. Friedman for additional clinical data. The histological slides and photomicrographs have been prepared by Mrs. E. Beck.

PELLAGRA IN A MORPHINE ADDICT

BY

CHARLES COMERFORD, M.D., D.P.M., D.P.H.

AND

BRIAN H. KIRMAN, M.D., D.P.M.

(From the L.C.C. Public Health Department, Observation Unit, St. Alfege's Hospital, and Bexley Hospital)

Quite apart from those areas where it is endemic and due to inadequacy of the local diet, or where it is associated with alcoholism (Deeny, 1942), pellagra has been recorded in a variety of conditions interfering with digestion and absorption. It is not uncommon in chronic psychotics and in cases with peptic ulcer—classes of patient who may limit their diet voluntarily. Cases in which morphine appears to have been the chief factor are rare (Bean, Spies, and Blankenhorn, 1944). We therefore record the following instance.

Case History

The patient, the widow of a medical practitioner, was said to have been a morphine addict for 12 years. She took the drug in the form of 1/3-gr. tablets hypodermically—at one time as many as 20 a day. Latterly she had taken only 12 a day. In one particular week she had taken 200 tablets. The usual amount was about 100 a week. She also took large quantities of aspirin. There was a history of dyspepsia but no radiological evidence of peptic ulcer, and it is certain, in view of her behaviour, that her frequent complaints of pain were efforts to obtain morphine.

Since the addiction developed she had taken little food. She ate no vegetables and little fruit. Occasionally she ate a lamb chop, but no other meat, no milk (except in coffee), and no eggs. Her diet consisted almost exclusively of white bread and butter, a little cheese, a little bacon, tea, and marmalade. She became very thin, in contrast to her former plumpness.

She had had attacks of diarrhoea at intervals for three years. These were controlled "only by morphia." She had had brown patches on her skin off and on for years, and used to be distressed about their unsightliness. They did not irritate, and they showed the usual seasonal variation. Since taking morphine she had been very moody—easily excited, then depressed. She rarely went out, and often made scenes—screaming, etc.—when the morphine allowance was finished. Her son dreaded coming home. She was admitted to the observation unit, St. Alfege's Hospital, on Aug. 7, 1941. She was pale, and the typical brownish branny patches on her skin stood out in contrast. In general the exposed areas were pigmented. There were particularly well marked pigmented patches over the manubrium sterni and nape of the neck, disposed "necklace" fashion, also on the backs of the fingers, wrists, and insteps. Her tongue was pale and very smooth. There was no fur, despite the poor appetite and the fact that she had taken so little food before admission. Her blood pressure was 110/70. There was gross oedema of the ankles

---

* This case will be published in full, together with two other cases affected by the same condition.

All tendon-jerks were absent. The patient said that they had been absent for years. She did not display the classical pellagrous dementia. Cerebration was quick and fairly accurate. She was hypochondriacal, and would resort to any device, from violence to wheedling, to get morphine. She was very self-centred. The blood Wassermann reaction and Kahn test were negative. A barium meal showed evidence of "gastritis" (thickening of rugae), with poor gastric tone and some initial delay followed by rapid emptying. No ulcer was demonstrated.

Progress.—The patient remained at St. Alfege's Hospital for 11 days, improving considerably and putting on weight. She had been extremely emaciated, with deep-sunken eyes, but at the time of her transfer had filled out considerably. No morphine was given, and after the first day no sedatives, although her craving persisted and she became very depressed when refused the drug. However, she soon became more reasonable and co-operative, and was willing to discuss other subjects than sedatives. On Aug. 18 she was transferred to Bexley Hospital, where a blood count showed Hb 44%, R.B.C. 2,430,000, C.I. 0.9. The patient was given large doses of iron and liver extract. Subsequent blood counts were as follows: Sept. 23—Hb 48%, R.B.C. 3,390,000, C.I. 0.71; Dec. 3—Hb 88%, R.B.C. 5,000,000. She was given nicotinic acid in 50-mg. doses six times daily, and thiamine in 50-mg. doses twice daily subcutaneously to a total of 1.8 g. Shortly after transfer she collapsed and was very ill for a few days. On recovery from this attack her physical improvement was progressive. She developed a ravenous appetite. There was at first no mental improvement, but four months after the beginning of treatment the mental state also changed for the better, and by mid-January, 1942, she had improved strikingly: She was quick, lively, cheerful, and took an active interest in her surroundings and in plans for her future. She was much less pale and the branny patches had become less evident. She was able to get about well and had put on much weight. There was still some oedema of the ankles on exertion. She was discharged home on Feb. 7, 1942.

When visited 16 months later the patient was active, able to walk several miles, and could do her housework; but unfortunately she had not co-operated in out-patient treatment, and was receiving no vitamin concentrates. She had deliberately restricted her diet on account of dyspepsia, and was taking only the small priority ration of eggs and milk which she was allowed, together with a very little bread-and-butter. She again had slight oedema of the ankles and branny patches on face, neck, arms, wrists, and hands; and her memory, especially for names, was poor. She declared that she was not taking morphia or alcohol.

Discussion

It is clear that in this case, as in most cases of vitamin deficiency, there was evidence of shortage of more than one essential factor (Sebrell, 1940). The main pellagrous picture is attributable to a nicotinic acid deficiency, but the polyneuritis and the cardiovascular disturbance suggest a thiamine lack, and the anaemia may have been due to a shortage of iron or of pyridoxine (vitamin B_6: Unna, 1940). The exact mechanism of causation cannot be determined with certainty, but the principal factor was probably the apathy and loss of appetite induced by morphine addiction.

The effect of morphine on digestion and absorption is complex. The secretion of digestive juices is diminished (Douthwaite, 1932; Edwards and Gunn, 1941), but the effect of this reduction is counterbalanced by a subsequent increase in the gastric secretion and by the fact that the food remains longer in the stomach and intestine. Thus there is no reduction in absorption attributable to the direct action of morphine. It does not therefore appear that direct disturbance of digestive function by the drug can have been a prominent factor in the production of pellagra.

A further possibility is suggested by the work of Shideman and Seevers (1941), which indicates that chronic morphine addiction and thiamine deficiency both produce the same sort of metabolic defect (characterized by a reduction of the normal increase in oxygen output from muscle following addition of pyruvate and co-carboxylase *in vitro*). Ellinger, Hassan, and Taha (1937) noted that dehydrogenases are inhibited by narcotics. This would not account for the pellagrous features of the above case, but might be partially responsible for the development of polyneuritis and oedema. The tendency, after cessation of therapy, to relapse without a return of the morphine addiction does not eliminate any of these possibilities, since, on the one hand, permanent metabolic changes may have been caused by the prolonged habituation to morphine, and, on the other, her diet after discharge was probably inadequate.

Summary

A case of pellagra in a long-standing morphine addict is discussed. There were also polyneuritis and anaemia. Great improvement occurred with treatment, followed by relapse on cessation of therapy. Loss of appetite due to morphine was thought to be the cause of the pellagra. (The possibility that morphine may disturb metabolism more directly is considered.)

Our thanks are due to Dr. Eli Davis, deputy medical superintendent, St. Andrew's Hospital, Bow, for his help in diagnosis and treatment of the patient and for his assistance in the compilation of this report.

MALARIA EPIDEMICS AT EXCEPTIONALLY HIGH ALTITUDES IN KENYA

BY

P. C. C. GARNHAM, M.D.Lond., D.P.H., Dip. Méd. Malariol., Paris

Medical Research Laboratory, Nairobi

Malaria in tropical and subtropical countries is usually thought to disappear once a certain altitude is reached, though the accepted "safe" height varies from place to place. Six thousand feet is usually regarded as the upper limit. Manson-Bahr (1941) quotes figures for Abyssinia which indicate that the transmission of malaria in that country ceases at 6,600 feet, though doubtful records exist of cases of benign tertian malaria at Addis Ababa at 8,175 feet. Schwetz (1942) in a review of the African literature gives limits up to 5,000–6,500 feet.

Hitherto in Kenya Colony malaria was thought to be absent from places above 7,000 feet. In June, 1941, a small farming community at Londiani (7,500–7,800 feet) was suddenly stricken by a severe epidemic of the disease. On 12 of the 14 farms at least one European became infected between June and August, and on every farm cases of malaria were numerous among the African labourers. Blood slides taken from 35 ill Africans (of non-immune tribes, and long resident in the district) were examined, and 27 showed malaria parasites. Twenty-six of these infections were *Plasmodium falciparum*, and one was *P. vivax*. This represented only a small sample of the total number of cases. The European infections were malignant tertian with the exception of a single case of benign tertian.

The Londiani district (75 miles from the provincial centre, Kisumu) comprises a small township with an Indian bazaar and native location surrounded by European farms extending for a radius of about 12 miles. There was also at the time of the outbreak a large military camp sited at Londiani. Bordering the farms there are extensive areas of forest reserve in which live African squatters numbering several thousands. The epidemic particularly affected the farms and the military camp, though in the latter many of the cases may have been relapses from infections contracted elsewhere. It is interesting to note that little malaria occurred in the isolated huts of the forest squatters.

The epidemic came to an abrupt end in August, 1941. Smaller outbreaks occurred in 1942, 1943, and 1944, at the same season.

Many of the cases were severe because treatment was delayed, the reason for the delay being that malaria was not thought of in these cold highlands. In 1943 several cases with typhoid-like symptoms and nearly moribund were seen; and these were proved to be malaria only by finding rings and schizonts of *P. falciparum* in the blood. The same curious localization of cases occurred in the later years: in November, 1943, through the kindness of the military authorities, I was permitted to examine 300 Italian prisoners of war who had been resident for at least six months in the Londiani camp, and not a single one showed malaria parasites in the blood slides (thick drop preparations).

Much of the country at Londiani is vlei land, and in rainy weather becomes waterlogged, providing ample facilities for mosquito breeding. Dammed streams, quarry pits, roadside drains, and seepages are also common anopheline breeding-places. Table I gives the results of several mosquito surveys undertaken at Londiani.

TABLE I.—*Anopheline Mosquito Surveys—Londiani*

Jan., 1944 ..	*A. christyi* (2) and *natalensis* (1)	*A. christyi* (255) and *squamosus* (5)

* Adults were collected from native huts, cattle-sheds, and river-banks. All *gambiae* came from dwellings.

Of the seven species represented at Londiani only one—*A. gambiae*—is a known vector of malaria. The salivary glands of all the adults collected were examined for sporozoites, but no infections were found. (The glands of one *A. gambiae* were very heavily infected with leptomonads.) These surveys indicate that *A. gambiae* breeds for a short period about May and that adults persist during the next two months. Climatic records for Londiani are shown in Table II.

* 1941 temperature records are not available. These figures represent the mean of 1942, 1943, and 1944 observations.

In May, 1944, the extension of malaria into the highlands of Kenya went one step further. An epidemic of a fatal disease was reported on a farm about 20 miles to the north of Londiani at an altitude of 8,300 to 8,500 feet. Twenty cases (among 220 inhabitants) showing symptoms of headache, backache, shivering, and fever were examined and blood slides were taken. Previously one woman had died after six days' illness (during the second half of which she had been semiconscious). Eight cases showed *P. falciparum* (including one with gametocytes) in the blood, and of these eight, six were proved not to have left the farm for at least six months. The fatal case was probably due to cerebral malaria. Most of the sufferers were Africans of the non-immune Kikuyu tribe and lived in huts scattered on the slopes of the hills and down by the streams. A mosquito survey revealed the presence of numerous anopheline larvae (*A. christyi, garnhami,* and *ardensis,* but no *gambiae*) and two very worn specimens of *A. gambiae* (females) in huts. Suitable breeding-places for *A. gambiae* existed in the cattle- and pig hoof prints in the swampy sides of the streams. The epidemic began about May 24, and the last case occurred on June 7. Malaria was apparently confined to this one farm; squatters living in the adjacent forests were unaffected. Climatic records of a B.E.A. meteorological station about 10 miles from this area and 500 feet higher are shown in Table III.

TABLE III.—*Climatic Records, 1944—Equator Station (9,000 feet)*

Month	Rainfall in Inches	Temperatures in Degrees F.		
		Mean Max.	Mean Min.	½ Max. Min.
Jan.	0·34	68	45	57
Feb.	0·67	71	46	58
March ..	2·48	70	47	59
April ..	3·85	66	48	57

Oct.	2·14	65	46	55
Nov. ..	4·53	64	47	55
Dec. ..	1·11	64	47	55

Temperatures on the affected farm were probably 2° F. higher.

Discussion

Malaria at these surprisingly high altitudes (7,500–8,500 feet) must be governed by three factors at least—the presence o human carriers, a range of rainfall and temperature suitable fo the breeding of *A. gambiae,* and a temperature above the know minimum, to enable the parasite to develop in the mosquito

The carrier problem is simple. Most farms employ larg numbers of Africans who come from the malarious lowlands o the province, and these men, and more particularly the childre who accompany them, provide a good source of gametocytes

The climatic factors concerned in the breeding of *A. gambia* are rainfall and temperature. This species is essentially dependent upon rainfall, and Tables II and III show that it i adequate at Londiani and at the Equator station. Variou authors (De Meillon, 1934; Leeson, 1931) give a mean temperature of not less than 61° F. as the limit for *A. gambiae.* O the farm below the Equator station this temperature is reache in one month of the year only—in March—when the mean i 59° + 2° = 61° F. At Londiani, four months—February, March April, and May—appear to be suitable, though the low rainfal of February invalidates that month for *A. gambiae* breeding A sudden drop in temperature occurs in June, and this presumably inhibits further breeding until the rains and highe temperatures of the succeeding year.

Lastly, there is the sexual cycle of the parasite in the mosquito to consider, and if outside (shade) temperatures were alon to be reckoned with it is obvious that development could no occur. Wenyon (1926) states that a minimum *constant* temperature of 64.4° F. is required for *P. falciparum,* and at this temperature development probably takes three weeks at least. A the Equator station hourly readings showed that temperature above 64° F. were attained for not more than two hours in th 24. At Londiani the mean temperature never reaches th critical figure. The answer to the problem is provided by th domestic habits of this species of mosquito. *A. gambiae* spend most of its life in human habitations—viz., small thatched huts with no windows or ventilation, with fires burning night an day, and overcrowded at night with people and goats. In suc circumstances the temperature is 5 to 10° F. higher than tha prevailing outside. This suggests that the mean temperatur inside huts on the "Equator farm" was 59°+5° F., and a Londiani 61°+5° F., during the month of May. These figure just suffice for sporogony of *P. falciparum.*

The meteorological conditions are such that the survival *A. gambiae* throughout the year is extremely doubtful in th case of Londiani and impossible in the case of the "Equat farm," and it is reasonable to assume that the mosquito introduced annually by road or rail transport. Partial co firmation that the latter occurs is provided by the results searches of trains arriving at Kisumu. Sixty-three *gambi* were caught in the coaches in the years 1943 and 1944.

It is unlikely that Wynter-Blyth's (1943) explanation of t occurrence of malaria at exceptionally high altitudes in t

Nilgiris (6,300 feet) applies here. He suggested that warm winds blowing from below brought the mosquitoes up; here they would have to be blown 20 miles, up 4,000 feet, and through a narrow twisting valley, which is inconceivable.

A hypothetical diary of events of the epidemic on the "Equator farm," based on the above considerations, is as follows:

(i) Gravid *A. gambiae* were transported to the farm in motor vehicles coming by road from a malarious valley 20 miles below. *March.*

(ii) Eggs laid and first (and only) generation emerged. *Beginning of April.*

(iii) These adults bit African gametocyte carriers. *April.*

(iv) Sporozoites in glands. *About May 13.*

(v) Human cases. *May 24 to June 7.*

(vi) Death of last infected mosquitoes. *About May 27.*

Summary

Epidemics of malignant tertian malaria began for the first time in Londiani in the year 1941 and were repeated on a milder scale in succeeding years (May to July). The altitude of the locality is 7,500 to 7,800 feet. A few cases of benign tertian malaria also occurred.

In 1944 a localized outbreak of malignant tertian malaria occurred on a farm about 20 miles to the north of Londiani, at an altitude of 8,300 to 8,500 feet. It lasted for a fortnight only.

Anopheles gambiae Giles was found at both places, and is the probable vector.

Climatic records indicate that the breeding of this species is possible at 8,300 feet only during the month of March and at 7,500 feet only during March, April, and May.

Temperature records suggest that the completion of the sporogonic cycle is possible only because *A. gambiae* spends practically all its life indoors, where the temperature is several degrees higher than outside. The external environment is too cold for development to occur.

It is probable that *A. gambiae* is reintroduced annually by road and rail transport.

I have to thank the Hon. Director of Medical Services, Kenya, for permission to publish this paper, and Mr. J. O. Harper, Entomological Field Officer, for help in some of the mosquito surveys.

Medical Memoranda

Mediastinal Emphysema and Bilateral Pneumothorax after Tracheotomy

The following case of complications after tracheotomy is thought to be interesting enough to be put on record.

CASE REPORT

Early on Christmas morning I operated on a little girl, 2½ years old, suffering from acute asphyxia; by 10 a.m. (10 hours afterwards) the child had died. The obstruction had come on quite suddenly the previous evening. There was marked retraction of the intercostal spaces and the suprasternal notch; the throat was injected, but no membrane was seen. The temperature was 100° F. The mother stated that there had been an alteration in the voice for some time.

Tracheotomy was performed in the usual way without undue haste under light general inhalation anaesthesia. The engorged veins over the trachea were ligated to preserve haemostasis; the layers of the cervical fascia were then incised—the pretracheal transversely—and the tracheotomy tube was inserted without difficulty through an opening made into the trachea. The breathing improved as a result, but did not seem to be completely relieved. On return to the ward the child's condition was fair, but later she became cyanotic, gasped for breath, and finally stopped breathing and died.

I am indebted to Dr. Donald Teare for the post-mortem findings: "Small wart-like papillomata of the vocal cord, tracheitis, acute bronchitis, emphysema of the mediastinum (some of the bullae being 2 cm. in diameter), and bilateral pneumothorax were found." He adds the comment that "acute respiratory infection was superimposed on the papilloma of the cord so that the tracheotomy did not completely relieve the respiratory distress." Though this is the first case of this nature that I have encountered, it would appear from the literature that this complication is not so rare as might be supposed. Minor degrees of emphysema of the mediastinum probably resolve and are therefore overlooked unless a radiograph is taken, and severe conditions, with pneumothorax ending fatally, may not be properly diagnosed unless the disaster which has overtaken the lungs is recognized.

At operation a suture was placed at the top end of the wound because a deep and rather mobile trachea necessitated a long incision, as is often the case in a child, otherwise the wound was left open and lightly packed with gauze beneath the cannula. Close suturing has been thought to be a possible cause (C. Jackson). There is no reason to suppose that the pleural dome was injured at the time (another cause cited). The usual explanation given is that air enters through the wound in the cervical fascia, becomes imprisoned in the mediastinum, especially when the obstruction is not relieved, and finally reaches a tension high enough to rupture the mediastinal pleura, which is generally thin, particularly in children. When there is a pneumothorax there seems always to be a coexisting mediastinal emphysema; the pneumothorax too is usually bilateral.

Michels (1939) has suggested the preliminary use of the bronchoscope to restore an adequate airway as early as possible and so convert a struggling and restless child into a quiet one. At operation it would seem desirable to disturb the layers of the cervical fascia as little as possible after incising them. The possibility of the sudden onset of pneumothorax as a complication after operation, as shown by hyperresonance, a displaced heart, and absent breath sounds, must be kept in mind, and appropriately treated by aspiration when it appears.

An Unusual Case of the Labyrinthine Fistula Symptom

Rarefaction and compression of air in the external auditory meatus producing nystagmus, giddiness, or other labyrinthine reactions is known as the labyrinthine fistula symptom. The syndrome is caused by the partial destruction of the bony wall of the labyrinth (commonly by chronic otitis, rarely acute), so that alterations in atmospheric pressure within the external auditory meatus are transmitted through the perforated drum membrane to the labyrinthine fluid. This syndrome is important because it indicates direct communication between the infected middle ear and the labyrinth, and in consequence requires special care.

CASE HISTORY

The patient, a man aged 35, was admitted to the West Middlesex County Hospital on Aug. 28, 1943, having had right otorrhoea of 16 years' duration. The ear had been operated on in 1927, a few weeks after onset of aural discharge, when an incomplete mastoidectomy was performed. For eight days previous to admission he had complained of right-sided headache. This had been followed five days later by the development of pain in the right ear, accompanied by true vertigo—objects in the room moving round him in a horizontal plane—and effortless vomiting. He could not say whether objects moved right to left or left to right. Once during those eight days, while lying in bed on his right side, he had felt "giddy" and vomited.

On examination there was a non-pulsating offensive purulent discharge from the right ear. No nystagmus was obtained when carrying out the so-called "labyrinthine fistula test" (rarefaction and compression of air in the external meatus). There was no tenderness over the mastoid. No abnormality of the central nervous system was found, and the C.S.F. was normal. The discharge gave a growth of anaerobic streptococci and the blood count showed a moderate leucocytosis. The history was suggestive of a labyrinthitis. However, signs of the labyrinthine fistula symptom remained negative, although the patient consistently complained of giddiness and headaches.

Three days after admission he dreamt* that he was in a motor-car which was going round and round, faster and faster, from right to left. When he awoke he was violently sick. Inquiry revealed that he had been lying with his right temporal region pressing on the edge of the mattress. Pressure was applied to that region just above the auricle, when a horizontal rotary nystagmus—slow movement to the left—occurred, and the patient had a recrudescence of the above symptoms. It was noted that the old operational scar was more extensive than usual and reached high up on the right temporal region. The E.N.T. surgeon was consulted, and it was decided that the reason for obtaining nystagmus in this unusual site was that connecting the external scar with the labyrinthine fistula was a band (probably fibrous) which transmitted to the labyrinth pressure applied to the external scar.

---

* Dreams in patients suffering from labyrinthitis with fistula symptoms were described by K. Eisinger and P. Schilder in *Mschr. Psych. Neurol.*, 1929, **73**, 314.

A radical mastoidectomy was performed. The bone was found to be sclerotic, and the middle ear contained granulation tissue, pus, and a cholesteatoma. There was a fistula extending to the horizontal semicircular canal, filled with granulation tissue, down to which the fibrous tissue of the old incision extended. Thus the suggested causative mechanism was confirmed.

COMMENT

This case has been recorded as an interesting example of the "labyrinthine fistula symptom," in which nystagmus and giddiness were obtained by pressure over the temporal bone and not on compression or rarefaction of air in the external meatus. The narrow external meatus and the scar condition which had developed after the first operation explain this abnormal symptomatology.

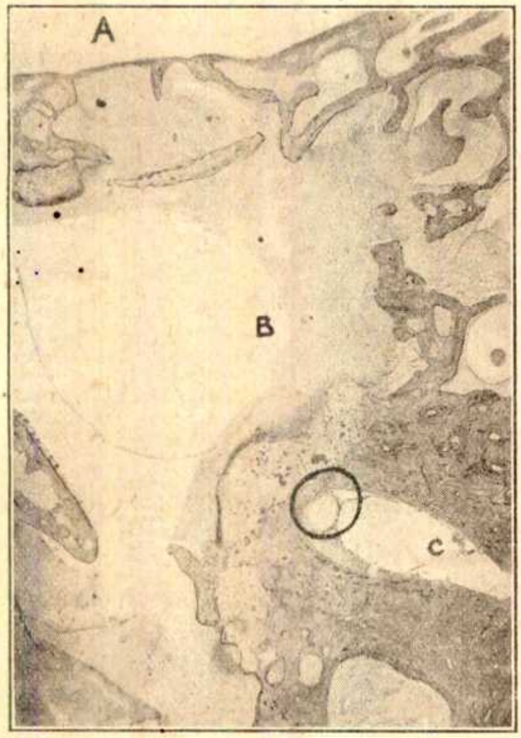

FIG. 1.—A, the middle fossa. B, the antrum. C, the interior of the horizontal bony labyrinth.

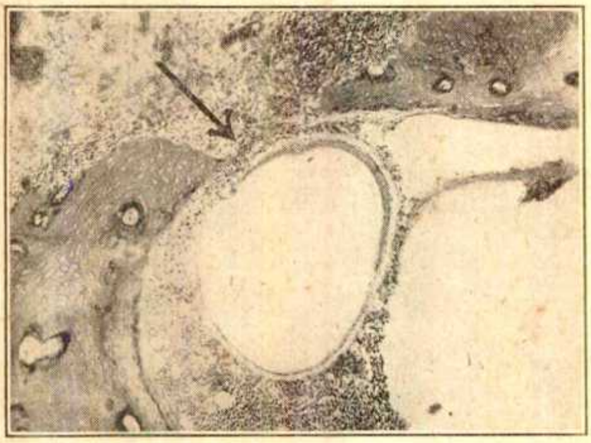

FIG. 2.—High-power field of marked circle in Fig. 1. The fistula is indicated by an arrow.

The photomicrographs taken from a case of purulent labyrinthitis, explain the mechanism of the fistula symptom, demonstrating the perilymphatic space exposed through the erosion of the bony semicircular canal. This histological section was kindly lent to me by Mr. Eisinger, E.N.T. surgeon attached to this hospital.

Reviews

THE AMINO-ACIDS OF FOOD

The Amino-acid Composition of Proteins and Foods. Analytical Methods and Results. By Richard J. Block, Ph.D., and Diana Bolling, B.S. (Pp. 396. $6.50 or 36s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox.

The publication of this well-produced, if rather high-priced, monograph is timely for two reasons. First, it collects in one place data that have so far been available only after prolonged search in a widely scattered literature; secondly, it shows how very much more work is needed if we are to have anything like a complete picture of the amino-acids required by man and of their quantitative distribution in his foods. The authors are well-known authorities in the United States, where they have carried out and published new or improved methods for estimating histidine, threonine, leucine, *iso*-leucine, and valine, as well as extensive studies in protein chemistry, notably on serum protein and on keratin and allied substances.

One would therefore expect their book to have a strong practical bias, and in this one is not disappointed. The general lay-out of the first eight chapters is similar: methods for breaking down the proteins of food are given, and these are followed by accounts of any essential separations that must then be carried out before the application of more or less specific tests for individual amino-acids. In these chapters the authors consider in turn the diamino-acids (arginine, histidine, lysine, hydroxylysine, and citrulline); the aromatic amino-acids (tyrosine, tryptophan, phenylalanine, diiodotyrosine, and thyroxine); the sulphur-containing amino-acids (cystine, cysteine, and methionine); the β-hydroxy amino-acids (serine and threonine); the "leucines" (leucine, *iso*-leucine, and valine); the dicarboxylic amino-acids (aspartic and glutamic acids); glycine and alanine; and proline and hydroxyproline. Each of these specialist chapters ends with detailed tables showing the amounts of the relevant amino-acids present in food and other proteins, in so far as this information is available. Some of it is doubtless new and derived from the authors' own laboratory.

In Chapter IX attention is turned to a consideration of general methods for amino-acids—and here there are certainly to be found matters of interest to others than those concerned with practical problems of food composition. That the book has gallantly struggled to keep up to date with a very rapidly moving subject is witnessed by the inclusion here of brief references to the partition chromatography introduced by Gordon, Martin, and Synge, and extended by these workers and by Catch, Cook, and Heilbron—an all-British contribution to this branch of science—as well as to the microbiological methods now being rapidly developed at several laboratories in the United States. Both these procedures will doubtless deserve and get much more detailed attention in the many subsequent editions of this admirable monograph, to which we look forward with interest and the certainty of profit.

A tenth chapter consists of summary tables. There is a slight dogmatic tendency, hardly justified by the experimental evidence available, to be found in the authors' inclusion here of data on the daily quantitative amino-acid requirements of man. Further, they have included histidine in the category of "essential," in spite of the findings of Rose, Haines, Johnson, and Warner, whose paper is not mentioned in the bibliography of some 700 titles. Nor are the titles mentioned of certain other papers by Holt and colleagues, and of yet others by the Rose group; these all bear on the problem of essentiality, not perhaps strictly germane to the book's main theme. Yet the conclusions of these papers are given in Chapter X, and the reader should surely be made able to consult the original papers—otherwise this chapter may appear to consist of summary tables in a sense not intended by the authors. Besides the bibliography there are both author and subject indexes, as well as an interesting and unusual page of typographical information. But the printer slipped once—when setting the title of Chapter VII in the table of contents (p. xiv). The authors, again, can surely not have meant to instruct the user of the polarigraphic cystine determination to keep the voltage constant.

However, criticism on these and other minor points is disarmed in advance by the authors' request for amendments and corrections: that so few errors or omissions can be found within the 300-odd pages is evidence of their enthusiasm and thoroughness. They and the publishers are to be congratulated, as are all those who will have sense enough, and the good fortune, to acquire a copy of what can become in the course of a very few days an invaluable—even an indispensable—companion in any laboratory or office where food is of the essence of the problem.

DECLINING POPULATION

Population Facts and Policies. By Eva M. Hubback. (Pp. 47. 2s. 6d.) Published for the British Social Hygiene Council by George Allen and Unwin.

Miss Hubback's pamphlet gives a clear and impartial summary of the demographic facts which lead to the conclusion that our population will decline and of the remedies or palliatives which have been proposed. We need not summarize these—we have done so many times; perhaps, however, some general reflections may be permitted.

The various proposals of financial aid to parents are too vague for it to be possible to say definitely whether, let us say, a married couple with five children will, after satisfying the basic needs of the family, have as much to spend on "pleasure" as a childless couple *at the same economic level.* But common sense, even unfortified by statistics, suggests that the childless *will* have a good deal more to spend on themselves. That is no doubt why so much stress is put, and quite rightly put, upon the moral advantages of old-fashioned family life. Still, human beings are imperfect, and the question may be asked whether the simplification of life which war conditions imposed might not, if it became a permanent feature of our civilization, do a good deal more for family life than anything else. One does not miss luxuries and pleasures which nobody can enjoy. One envies somebody, not nobody.

LESIONS OF THE SHOULDER

Shoulder Lesions. By H. F. Moseley, D.M., M.Ch., F.R.C.S., F.A.C.S. (Pp. 181; illustrated. $4.50 or 25s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1945.

The tendency to produce monographs upon very limited aspects of the subject of surgery continues; one of the most recent additions to the list is *Shoulder Lesions*, by H. F. Moseley, of McGill University. The advantages of such monographs are here well displayed, for the surgeon will find a much more satisfying and practically useful account of the various troubles which arise around and in the shoulder-joint than he could possibly expect in even the best general book on orthopaedic surgery. As the author correctly points out, far too little attention has been devoted to many shoulder lesions, considering their frequency.

The first two chapters, upon the mechanism and examination of the shoulder respectively, are excellent, and there is a good description of the scalenus syndrome in the neurological chapter, which is by Dr. McNaughton. Recurrent dislocation of the shoulder is fully discussed, the author's conclusions being that the Bankart operation is superior to all others in that it is a direct repair of the pathological lesion. Derangements of the so-called "rotator cuff" receive adequate attention. The illustrations, especially the skiagrams, have reproduced well.

The general production of the book is up to the high standard set by Messrs. Charles C. Thomas for their publications, but the appearance of an ordinary cartoon, depicting patients with shoulder lesions crowding into the doctor's surgery, on page 146, is a little incongruous and seems out of place in a book of this kind. Will the next "advance" be the introduction of the comic strip into serious medical works?

Notes on Books

Gonorrhoea is a collection of twelve articles on the subject published by the U.S. Office of War Information. The first, entitled "The Management of Gonorrhoea in General Practice," carries the authority of the American Neisserian Medical Society and should be an excellent guide for the general practitioner in not only the treatment but the handling of cases of gonorrhoea. It is pointed out that the mere treatment of the disease does not constitute the sole duty of the doctor; he must diagnose correctly, see that contacts are followed up, and ensure that the patient is really cured. No mention is made of penicillin, but the use of this antibiotic is described in subsequent articles; there is an excellent "reading list" appended. Other articles include "Treatment of Gonorrhoea," issued by the U.S. War Department, giving the details of routine penicillin administration; "Studies on the Action of Penicillin"; "The Treatment of Sulphonamide-resistant Gonorrhoea with Penicillin"; "Penicillin in the Treatment of Ophthalmia Neonatorum"; "The Successful Treatment of Gonorrhoea with a Single Injection of Penicillin." This is an up-to-date symposium, and all those who treat gonorrhoea will do well to consult it if they are fortunate enough to obtain copies through the Librarian at the American Embassy, 1, Grosvenor Square, London, W.

The second edition of Dr. J. **BAILEY CARTER**'s *Fundamentals of Electrocardiographic Interpretation* (Springfield and Baltimore: Charles C. Thomas; $6.00 post paid) has unfortunately a large proportion of poor illustrations. Many are photographically bad, or reduced to such small size as to be hard to read. The text is too scanty, and much of the extensive bibliography might well be reduced to leave room for more. The index is inadequate. The discussion on chest leads leaves even the experienced reader in some confusion. Nowadays pressure on the carotid sinus has long displaced "pressure on the vagus." There are omissions such as ventricular fibrillation as a cause of Stokes-Adams attacks; parasystole is not mentioned; the discussion of bundle branch block is out of date. Neither the student nor the more advanced reader will find this book of much assistance.

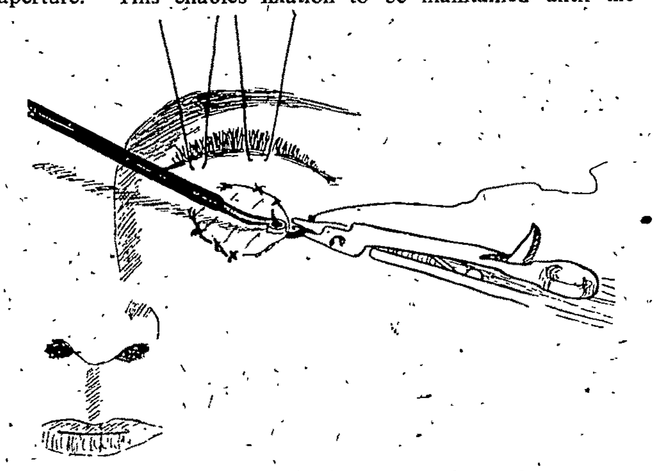
Hayfever Plants, by **ROGER P. WODEHOUSE**, Ph.D., of the Lederle Laboratories, has appeared as Vol. XV of a new series of Plant Science books edited by Frans Verdoorn. It is published by the Chronica Botanica Company, of Waltham, Massachusetts, U.S.A., and by William Dawson and Sons Ltd., London, W.1, at the price of $4.75 or 30s. The purpose of the book (which most readers in Europe will find far too comprehensive) is to bring together the botany that should be known in order to gain a clear understanding of the part that plants and their pollens play as causes of the allergies, of hay-fever and asthma. As the subtitle indicates, the plants are dealt with in regard to their appearance, distribution, time of flowering, and their role in hay-fever, with special and very detailed reference to the flora of North America. Chapter 1 is on the botany of hay-fever; Chapter 2, on hay-fever plants—gymnosperms; Chapter 3, on hay-fever plants—angiosperms; and Chapter 4 is entirely devoted to regional surveys in North America.

Preparations and Appliances

DEVICE FOR FIXATION OF A WOLFE GRAFT

Major I. C. **MICHAELSON**, R.A.M.C., ophthalmic specialist, writes:

The accompanying sketch shows a simple device for the fixation of a thin Wolfe graft while it is being stitched into the receiving area. There is a narrow slit opening in the ring just wide enough to allow the thread to be brought out from the aperture. This enables fixation to be maintained until the



needle has been drawn completely through the graft and aperture. The under surface is grooved to permit better fixation.

The purpose of this device is to avoid the trauma inevitable with forceps and the time spent when a plastic hook is used. It has proved of service in the work of plastic and ophthalmic units in the Middle East.

The appliance is made in stainless steel by Messrs. Down Bros. Ltd.

THROMBO-EMBOLISM

For many decades after Virchow[1] established the embolic basis of infarction of the lung the magnitude of the clinical disaster of pulmonary embolism distracted attention from the source, usually symptomless, of the responsible clot. More recently clinical interest has turned from the lost horse to the stable door, and a symposium in the February number of *Surgery* finally relegates pulmonary embolism to its proper pathological perspective as an occasional effect, simple and mechanical, of a common but rather complicated pathological process. The term "thrombo-embolism" covers all thrombosis, overt and occult, and the embolism which occasionally results from it. Denecke[2] first suggested that the primary thrombus which precedes pulmonary embolism develops not in the femoral and iliac veins, which had previously been suspect, but in the deep veins of the calf and foot. This was confirmed by Rössle,[3] who, at 324 consecutive necropsies, found thrombi in the calf veins in no less than 27%; in nearly a third of these there was a concomitant femoral thrombosis, but the ilio-femoral vein was alone affected in only 2.1%. W. G. Hunter and his associates[4] have traced 9 out of 11 pulmonary emboli to the legs. Thrombo-embolism is not solely a post-operative phenomenon; it may occur in any adult patient who is confined to bed; it is, however, particularly common at certain ages and after certain operations. Barker and others,[5] in a study of 172,888 operations performed in the Mayo Clinic, reported that thrombosis and embolism were twice as common after laparotomy, and three times as common after trans-abdominal operations on the pelvic organs, as after other operations, and that they occurred most often after extensive resections of abdominal organs. De Takats and Fowler[6] recognize in the veins of the lower extremity certain types of thrombosis which, though fairly well defined, may merge into each other by growth of thrombus.

1. Superficial phlebitis may develop, with large red painful thrombi visible and palpable, in pre-existent varices.
2. Ascending plantar vein thrombosis, not uncommon in younger patients, gives the tenderness which Payr[7] described over the lateral aspect of the foot, behind the internal malleolus, and along the posterior tibial vessels.
3. In calf muscle thrombosis, which often escapes detection until pulmonary embolism occurs, there may be cramp in the calf, and Homans's sign[5]—pain in the calf when the knee is extended and the ankle dorsiflexed—can be elicited.
4. Femoral thrombosis, associated as it usually is with "white-leg," is seldom followed by pulmonary embolism. Indeed, Homans has confidently affirmed that if an embolus does detach "one can be reasonably certain that it comes not from the vein of the swollen limb but from the other or innocent-appearing leg." Veal and Hussey[9] and Fine and Starr[10] report instances of pulmonary embolism occurring in the presence of "white-leg."
5. In pelvic vein thrombosis there are swelling and cyanosis of the thigh and sometimes buttock, distension of superficial veins, and, occasionally, slight suprapubic oedema, frequency of micturition, mucous diarrhoea, and firm cords palpable from the rectum; pulmonary embolism is not infrequent if the thrombus is confined to the hypogastric veins, less likely to occur after its extension to the upper pelvic veins.

Thrombosis in the deep leg veins is usually non-inflammatory. Hunter[4] found histological evidence of inflammation in only 2.5% of the thrombosed veins which he examined. For spontaneous coagulation there are presumed to be three important causal factors—slow circulation rate, increased coagulability of the blood, and injury to the intima of the affected vessel. The first of these can be ascribed predominantly to immobility in bed, and venous return may be further impeded by the pressure of an enlarged uterus, by gaseous distension of the abdomen, and by a tight abdominal binder. Flexion of the thigh can obstruct the ilio-femoral veins in the groin if the patient is kept sitting up in bed, and a "donkey" inserted under the knees to maintain that position can compress the popliteal and calf veins. Simpson[11] has reported a real increase in pulmonary embolism among elderly London people who developed "shelter leg" from sitting night after night in camp chairs, a wooden crossbar compressing the back of the calf. Some years ago a remarkable increase in the incidence of thrombo-embolism in a famous hospital abroad followed the introduction of a special type of bed designed to bring the patient effortlessly to a sitting position, hips and knees flexed, by the turning of a handle. Yet slowing of the venous circulation does not in itself cause thrombosis; blood remains fluid in a segment of vein isolated between two ligatures, provided the intima has not been damaged. Ochsner[12] summarizes certain post-operative blood changes which facilitate clotting: hypoproteinaemia, hyperglobulinaemia, increase in fibrinogen, polypeptide, peptidase, and calcium, acceleration of the sedimentation rate, exaggeration of the tendency of the platelets to agglutinate, and, if dehydration has occurred, increased viscosity of the blood. In addition, thrombokinase is presumed to be liberated from the operation field, and Barker[5] reports that the incidence of thrombo-embolism is precisely twice as high after bilateral as after unilateral herniotomy. Important as these post-operative blood changes may be, it has not yet been shown that they are more remarkable after those operations, and at those age periods, when thrombo-embolism is commonest. More convincing is the detection by de Takats[6] in the subjects of thrombo-embolism of a decreased heparin tolerance and even—though this has been more difficult to establish—of an increased prothrombin time in the diluted plasma. Injury to the intima, important in arterial thrombosis and post-traumatic venous thrombosis, seems to play little part in post-operative thrombosis and the thrombosis of recumbency. Perhaps the pressure of the calf on the mattress causes intimal bruising and decides the localization of the initial thrombus.

To prevent post-operative thrombosis, blood-flow in the lower extremities may be increased by massage and leg exercises, and blood return may be improved by forbidding abdominal binders, the sitting position, and bolsters under the knees, and avoiding abdominal distension. The Fowler position can safely be obtained by raising the head of the bed; this procedure not only avoids flexion at the hip but encourages leg movement—the patient actively tries not to slip downwards. The incidence of thrombo-embolism can be reduced still further by getting patients up soon after operation. Zava,[13] who allows patients to get up 24 to 48 hours after gynaecological operations, reports 6,000 operations without a single embolism, and Smith and Allen[14] have shown a 50% improvement in the circulation rate if patients are allowed up on the fifth day instead of on the tenth. Elevation of the lower limbs to 30 degrees also increased blood flow in the limbs, and Ochsner[12] advises pressure bandages to improve blood return. Dehydration should be controlled, too, to reduce blood viscosity if for no other reason.

To combat the disturbance of blood coagulability which seems partly responsible for post-operative thrombosis, anticoagulants may be administered. Barker and his associates[15] have given dicumarol after 1,000 operations. The patients were chosen for this form of prophylaxis either because the operation performed upon them (hysterectomy) is commonly followed by thrombo-embolism, or because they had already suffered, or were suffering, from thrombosis or embolism. No instance of thrombosis or of pulmonary embolism occurred in 438 patients who had been submitted to hysterectomy, and the incidence of thrombo-embolism in the whole series was significantly lower than in a comparable control series. The aim of the method is to produce a certain degree of prothrombin insufficiency, and, therefore, since susceptibility to dicumarol varies with the individual, the method is not entirely devoid of the risk of haemorrhage, and should not be employed without daily and constantly comparable estimation of the prothrombin time by the Quick method.[16] [17] The drug is given by mouth in a single daily dose—300 mg. on the first day and 200 mg. on each successive day; if the prothrombin time is less than 20% of normal on any day the dose is omitted. The full effect of dicumarol lags 24 to 48 hours behind its ingestion, and to obtain an immediate effect 50 mg. of heparin may be injected intravenously at four-hourly intervals during the first day or so of dicumarol administration. If bleeding occurs it can be controlled by blood transfusion, and the prothrombin time can be raised quickly to a safe level by an intravenous injection of 64 mg. of menadione bisulphite (synthetic vitamin K). Dicumarol therapy should not be employed in the presence of renal or hepatic insufficiency or a tendency to haemorrhage, and it should be given with special care in patients with exposed raw surfaces.

If, in spite of available preventive measures, thrombosis or embolism occurs and is detected, steps are taken to prevent extension of thrombosis and recurrence of embolism. Both lower limbs are elevated by raising the foot of the bed, and paravertebral sympathetic block may be induced to increase the circulation rate. Ligation of the affected vein may have some application, but precise indications for this operation are still not available. Allen, Linton, and Donaldson[18] advise ligation when, after a pulmonary embolism, the site of thrombosis is recognized in one or both calves, the thigh is not swollen, and the femoral vein is not tender, rather than in overt femoral thrombosis. They ligate the femoral vein just below the entrance of its profunda branch. Fine and Starr[10] advise femoral, iliac, or caval ligation according to the upper limit of the intravenous clot, and they perform the bilateral operation even if thrombosis appears to be restricted to one side. Dicumarol therapy seems also to be valuable after signs of thrombo-embolism have appeared. In 81 patients suffering from post-operative thrombosis or embolism de Takats found that in no case was there evidence of embolism or of extension of thrombosis after treatment had begun, and Barker's results were equally satisfactory. It is from recent, friable, non-adherent clot that emboli are likely to be detached; recurrent emboli seem to be due to progressive thrombosis, and if a thrombus can by the administration of anticoagulants be prevented from growing, emboli are not likely to occur or to recur.

The conclusions to be drawn from the recent literature of thrombo-embolism are (1) that a studied post-operative regime will lower the incidence of this complication; (2) that the careful daily post-operative examination of all adults for signs of thrombosis in leg and foot will permit detection of the early stages of thrombo-embolism; and (3) that measures for the prevention of embolism are increasing in number and effectiveness. Routine post-operative administration of anticoagulants is not likely to be generally adopted at present—standard tests for dosage control are not yet sufficiently simple—but the value and practicability of dicumarol therapy in preventing embolism or extension of thrombosis after thrombosis has actually occurred seem to be proved.

EXTERNAL PANCREATIC SECRETION IN MAN

The external secretion of the pancreas is regarded as being under a dual nervous and hormonal control. Pavlov[19] demonstrated that stimulation of the vagus nerve produced a secretion of pancreatic juice, small in amount but rich in ferments; Bayliss and Starling[20] and later investigators showed that the injection of secretin produced a large volume of alkaline juice poor in enzyme content. Even this clear-cut division of function between the nervous and hormonal stimulants may not be entirely true, as it has recently been shown that secretin-free extracts of intestinal mucosa will stimulate the secretion of pancreatic enzymes.[21] These observations are based on animal experiments, and the confirmation of some of them on human subjects has depended on two methods, neither of which is entirely satisfactory. The first of these is the collection of pancreatic juice by means of a duodenal tube, as, for example, in the work of Ägren and Lagerlöf,[22] who stimulated the pancreas by the injection of secretin. By this method the pancreatic juice is unavoidably contaminated by intestinal secretions. The second method is the study of juice obtained from fistulae of the pancreas—the sequel, usually, to an acute inflammatory condition of the pancreas or to drainage of a pancreatic cyst. It is obvious that the reactions of the pancreas in such pathological conditions may not be comparable with those of the normal organ. Using one or other of these methods various observers have found that the human pancreas, like that of lower animals, responds to the intravenous injection of secretin by the secretion of an alkaline fluid with a low concentration of enzymes. Attempts to demonstrate the effect of nervous stimulation of the human pancreas by the injection of various parasympathetic drugs have yielded contradictory results. Comfort and Osterberg[23] found that mecholyl chloride caused a marked stimulation of enzyme output by the pancreas. In cases of pancreatic fistulae, however, McCaughan, Sinner, and Sullivan[24] found that physostigmine and mecholyl chloride increased the flow of juice; whereas Miller and Wiper[25] found that physostigmine and pilocarpine diminished the rate of secretion. The marked side-effects of these powerful drugs may explain the discrepant results. All observers have found that the introduction of hydrochloric acid into the intestine is a powerful stimulus to pancreatic secretion. Comfort and Priestley,[26] who compared the effect of meals given by mouth and administered intraduodenally, have shown that the stimulant effect of carbohydrate and protein meals upon pancreatic secretion is probably secondary to their stimulant action upon the secretion of hydrochloric acid by the stomach. Fat, on the other hand, appears to stimulate pancreatic secretion by acting directly from the small bowel.

In general, therefore, the results in man agree with those obtained on animals in showing the importance of secretin for the production of the alkaline fluid, of gastric hydrochloric acid for the release of the secretin, and of the vagus nerve for the enzyme content of the juice. Two important gaps in our knowledge of the physiology of the pancreas remain unfilled either by animal experiments or by observations on man. These are the question whether the concentration of the enzymes of the pancreatic juice is adapted to the nature of the foodstuff being digested; and, secondly, the more general question of how the discharge in the vagal fibres of the pancreas is controlled. There is no doubt that in animals electrical stimulation of the vagus nerve brings about a parallel increase in the tryptic, lipolytic, and amylolytic activities of the pancreatic juice. Whether, when the vagal activity is increased during digestion, there is a selective increase in the secretion of one or other of the enzymes corresponding to the type of food being digested, and whether disease of the pancreas may selectively diminish the secretion of one enzyme (as Ägren, Lagerlöf, and Berglund[27] have suggested) is an unsettled question. The more general problem of how the vagal stimulation of the pancreas is brought about also awaits solution. In the case of gastric secretion the vagus is the efferent pathway for the production of the important psychic secretion. All observers, however, are agreed that any psychic effect on the pancreas is either feeble or nonexistent. Possible solutions of the problem are that the stimulation of the pancreas depends on long reflexes through afferent nerves from the intestine itself, or is brought about by some chemical stimulant in the blood acting on the vagal nucleus in the medulla during digestion.

MÉNIÈRE'S SYNDROME

The clinical diagnosis of Ménière's syndrome is nearly always easy, but the pathological basis of the lesion or stimulus which brings on these attacks is still unknown. A number of temporal bones have now been examined, and in some gross dilatation of the membranous labyrinth has been demonstrated; nevertheless we do not know the mechanism by which the labyrinthine storm is raised, and consequently treatment is empirical, such as destruction of the labyrinth or section of the eighth nerve. Shelden and Horton[28] based a method of treatment on the idea that alteration in the permeability of the capillary walls with local oedema is the probable aetiological factor, without specifying whether the oedema is likely to be intracellular or extracellular, and histamine was suggested as an agent which would perhaps affect capillary permeability. In 1940 and 1941 they reported[29] spectacular relief in certain cases by the intravenous injection of histamine. Now Lillie, Horton, and Thornell[30] present a review of 25 cases treated by injection of histamine but studied from a slightly different aspect. Of these patients 18 were men and 7 women, and their ages ranged from 27 to 65 years, with an average of 46. The treatment consisted in the intravenous injection of 2.75 mg. of histamine diphosphate (the equivalent of 1 mg. of histamine base) in 250 c.cm. of either normal saline or 5% solution of dextrose or 0.8% solution of potassium chloride, at the rate of 20 to 60 drops a minute. The administration was repeated daily for three to six days. Subcutaneous injections were also given, consisting of a 1–10,000 solution of histamine base, the dosage rising gradually by 0.05 c.cm. from 0.2 c.cm. to 1.0 c.cm. Audiometric studies of this series of cases showed that in 12 of the 25 the hearing was improved by the treatment, and in 6 of these the improvement was very noticeable. In 4 of these 6 the potassium chloride solution was used. Tinnitus was present in all but one case. In 10 there was no change, but in 2 cases the tinnitus disappeared, and it was much improved in 8. Vertigo was the symptom which showed the best response, for it disappeared completely in 19 cases, and in only 2 was there no change. These observers were not able to confirm the suggestion made by Atkinson[31] that such cases could be divided by intradermal testing into those sensitive and those insensitive to histamine. By such a selection of cases those insensitive to histamine could be treated in some other way, and Atkinson proposed the administration of nicotinic acid for its vasodilator effect, not for its action as a vitamin. Regarding tinnitus as a form of paraesthesia,[32] Atkinson has claimed that all vasodilators bring transient relief—an effect which can be produced by blocking the stellate ganglion or injecting drugs with vasodilator action. Using nicotinic acid as the vasodilator, he claims a high percentage of good effects in all forms of deafness accompanied by tinnitus.

From all this it appears that the control of the labyrinthine circulation may prove to be the factor in the successful treatment of Ménière's syndrome, but it is probably the circulation of the endolymph, rather than the vascular circulation, which needs to be controlled. However, very little is known about the endolymph, though by analogy it is probably secreted by the capillaries in the stria vascularis in the cochlea in the same way as the cerebrospinal fluid is secreted by the choroid plexus. The endolymph is probably secreted also from capillaries in the saccule and utricle and in the semicircular canals, but nothing is certain about this. It remains also to determine how the effect can be maintained in persons who respond favourably to histamine, and the continuation of maintenance doses by subcutaneous injections is suggested. This line of management is supported by the success which sometimes attends simple restriction of salt intake, the sodium ion being considered the morbid factor. Large doses of ammonium chloride are used to replace the salt—45 grains in capsules three times a day with meals. The success attending the small number of cases in which the histamine was given in a solution of potassium chloride is perhaps significant. There will, however, remain a proportion of cases in which the function of the labyrinth is so disordered that the symptoms will yield only to destruction of the labyrinth or section of the eighth nerve. Lillie, Horton, and Thornell give an excellent bibliography of the whole subject, of which the above commentary displays only one facet.

MEDICINE AND THE PROGRESS OF THOUGHT

In the recent course of lectures at Cambridge on the history of science Dr. A. E. Clark-Kennedy made an outstanding contribution on *The Art of Medicine in Relation to the Progress of Thought*. It is fortunate, therefore, that his lecture has now been published in book form by the Cambridge University Press (2s.). The very moderation of his claims adds to their effectiveness. Broadly speaking, he considers medicine exercised an influence only at three epochs—the Hippocratic Age, the Renaissance, and in modern times. In the first period the great achievement was to lay the foundation of the observational method in the study of natural phenomena, thereby adding to the progress of thought in a way which it would be difficult to overestimate. Disease was regarded as a disharmony of body or mind; in general the Stoical philosophy was adhered to and an ethical standard formulated. Galen, the aftermath of this epoch, by adapting Aristotle's conception of the relation of the soul to the physiology of the body, helped to prepare the world for the acceptance of individual responsibility and the Christian interpretation of human life. His teleological teaching was naturally attractive to the new faith, though the Pauline conception of the "vile body" was alien to him. At the Renaissance the biological studies of Vesalius and Harvey were based on physical concepts, and the body was regarded as a machine worked by mechanical laws, mind and consciousness being by-products of the material world. Hobbes accepted this view, and metaphysics was not yet ready to criticize it. Despite its own advances, medicine cannot claim to have made any other particular contribution to human thought in that age. When he comes to the modern period Dr. Clark-Kennedy finds it easier to speak of the achievements of medicine in the latter half of the nineteenth century than of its contribution to thought. Darwin and Pasteur exerted a profound influence, but neither of them was a medical man. In this century study from the medical aspect of genetics and psychology has had an effect scarcely less profound; it has influenced modern thought, education, and our way of life. Repressions, rationalizations, and the unconscious mind have become topics of conversation. If man is merely the resultant of his inherited genes and his environment the question of moral responsibility is raised in a peculiarly disconcerting form. But it is probable that psychology, leaving out of account the possibility of something introduced and influencing the mind from without, and tending to ignore the freedom of the will, gives only a partial explanation of the working of the human mind. If the increasing influence of medicine is to be rightly directed the present breach between science and humanism must be healed. These are only a few of the many thought-provoking topics in a lecture which establishes the author in the ranks of scholar-physicians.

BARNARDO CENTENARY

A service, attended by the Lord Mayor and Lady Mayoress, was held in St. Paul's Cathedral on July 4 to commemorate the centenary of Dr. T. J. Barnardo's birth and to give thanks for his work for children and the founding of the Barnardo Homes. The Bishop of Exeter in an address said that Dr. Barnardo was a great man, a seer, a man who saw defects in the law concerning children, a pioneer in whose footsteps many others had followed. Thomas John Barnardo was born in Dublin on July 4, 1845. After medical study in London, Edinburgh, and Paris he took the F.R.C.S.Ed. While at the London Hospital in 1866 his attention was drawn to the condition of waif children on the streets. He continued to investigate the subject and to labour in spare hours on their behalf. He established his first Home in 1867, founded a village for girls at Ilford in 1873, an institution for sick waifs in 1887, and formed the Young Helpers League in 1891. He died on Sept. 19, 1905. Before his death he had rescued and trained over 59,000 destitute children and had otherwise helped a quarter of a million children in want.

The next session of the General Medical Council will begin on Tuesday, July 17, at 10.30 a.m., when the President, Sir Herbert Lightfoot Eason, will take the chair.

The Yorkshire Cancer Campaign was launched in 1925, and next year will therefore see the coming of age of cancer research in Yorkshire, guided by a strong medical and scientific committee and carried out by members of the staff of the department of experimental pathology and cancer research at Leeds University and also at Sheffield. The 19th annual report was presented on June 4. It includes an account by Prof. R. D. Passey of the work of the department at Leeds, with special reference to experimental carcinogenesis, experimental bladder cancer, and an inquiry into the question whether arsenic is really capable of giving rise to malignant disease. There is also a report of progress in the radium department of the General Infirmary at Leeds. Prof. H. N. Green supplies an account of research on cancer in the department of pathology at Sheffield University. As in the two previous years, the main work there has been an attempt to elucidate factors which may modify the pathogenesis of tumours induced by 2-acetyl aminofluorene. Studies of constitutional factors have started, and dietetic and hormonal factors are being investigated.

MEDICAL REHABILITATION IN HOSPITAL*

BY

HARRY PLATT, M.D., M.S., F.R.C.S., F.A.C.S.

Professor of Orthopaedic Surgery, University of Manchester; Consultant Adviser in Orthopaedic Surgery, Ministry of Health (Emergency Medical Service)

A comprehensive rehabilitation scheme, in the modern sense of this term, is a two-stage process. The *first stage* is that of *medical rehabilitation*, which covers the period extending from the beginning of an illness or injury to the end of convalescence and reconditioning. This stage is primarily the concern of the medical man and his team of auxiliaries. The *second stage* is that of *social* and *industrial rehabilitation*, in which the victim of illness or accident, after having been restored to the maximum degree of fitness possible under the circumstances, is resettled in his former occupation or trained to follow a new occupation. In the past, the social and industrial aspects of rehabilitation have depended almost entirely on the zeal and activities of voluntary organizations. But now the State has entered the field as a powerful reinforcement, through the new functions of the Ministry of Labour.* But I would emphasize the view that there is no clear-cut dividing-line between medical rehabilitation and social or industrial rehabilitation as it concerns the sick person. The whole process is indivisible. The hospital physician or surgeon who is interested in his patients as men and women conditioned to a particular social or industrial environment must of necessity want to learn how successfully—if indeed at all—they have become adjusted to the mental and physical stress of the old work or the new vocation. The medical man must also be prepared to challenge, if need be, the suitability of the new working conditions. And equally the social worker, whether lady almoner or Ministry of Labour rehabilitation officer, must come into action during the stage of medical rehabilitation. They should make their first contacts with the hospital patient before his period of treatment and re-enablement has ended. This early contact is provided for under the Disabled Persons (Employment) Act of 1944—a notable piece of social legislation which is the outcome of the Tomlinson report (1942). The complete scheme of rehabilitation is in its infancy, but we can look forward to a time in the near future when the harmonious blending of remedial and social measures will be one of the outstanding features of our health services. Furthermore, there are signs that certain industries may make a contribution to the stage of medical rehabilitation by providing workshops in which lighter forms of occupation can be deliberately prescribed on a curative and remedial basis. This experiment is now under trial in the Austin Motor Company's works at Birmingham in conjunction with the Birmingham Accident Hospital, and is meeting with conspicuous success.

History of Medical Rehabilitation

In the age of Pericles we find that Hippocrates gave clear instructions for the rational use of sun, air, water, and above all *exercise*, as a means of restoring the injured and sick to health. Hippocrates, it is interesting to learn, understood the importance of balancing a regime of *exercise* with a regime of *rest*. The respective roles of rest and exercise have been the subject of debate again and again during the 2,000 years and more which have elapsed since the founding of the Hippocratic school of medicine.

The end of the eighteenth century and the earlier years of the nineteenth were the period of the founding of the earliest orthopaedic hospitals in various European countries, including Great Britain. As this was long before Lister had made operations safe by the introduction of the antiseptic technique, non-operative methods of treatment held the field. The Orthopaedic Institute founded at Montpellier, in France, in 1825 is deserving of special notice, for it was perhaps the first of the country orthopaedic hospitals—the forerunner of hospitals which are so familiar to us to-day. This institution was set up in a park on the outskirts of Montpellier and was equipped on almost a lavish scale for gymnastics, games, and other forms of recreational therapy—in short, for many of the remedial measures included in the modern programme of medical rehabilitation based on our wartime hospitals. Since those early days orthopaedic hospitals and orthopaedic surgeons have played the predominant part in the development and organization of the expanding techniques of rehabilitation, and have been responsible for their inclusion in the armamentarium for the treatment of crippling disease and injury. It was Sir Robert Jones (1858–1933), the greatest master of orthopaedic surgery of modern times, who during the First World War gave us the following definition of the sphere of action of the orthopaedic surgeon: "The treatment by manipulation, operation, re-education and rehabilitation of the injuries and diseases of the locomotor system."

The First World War, 1914–18.—This was the period when the present-day concept and practice of medical rehabilitation first took shape. Many will remember the splendidly equipped military orthopaedic hospitals, as they were called, which Sir Robert Jones, after much opposition, was permitted to organize. There was the parent hospital at Alder Hey, Liverpool; the Shepherd's Bush Hospital in London—the greatest of them all; there were military orthopaedic centres at Birmingham, Oxford, Leeds, Edinburgh, Glasgow, Aberdeen, Belfast, and Manchester. In all these hospitals a wide range of rehabilitation facilities was installed—departments of physiotherapy for massage and electrical treatment; departments of hydrotherapy, with whirlpool baths as the popular treatment; gymnasia for class exercises and fast-moving games; and curative workshops equipped for both light and heavy crafts. Rehabilitation programmes were devised for patients immobilized in bed owing to gunshot fractures of the lower limbs, as well as for those who were ambulatory. A full "working day" was followed with the various types of remedial and diversional therapy represented in a programme for each patient. But in the military hospitals of that day the cost of rehabilitation facilities—apart from massage, the simpler forms of electrical treatment, and remedial exercises—was not provided by the Treasury under the Army vote. It was the B.R.C.S. who came forward to fill the gap, and by generous gifts of money enabled these special centres to set up remedial departments on a scale hitherto unknown in Great Britain, or indeed elsewhere.

After the U.S.A. entered the war against Germany, the British scheme of special military orthopaedic hospital centres was adopted and brought to a high pitch of efficiency by Col. J. E. Goldthwait, of Boston, one of the leaders of orthopaedic surgery in America at that time. In the American scheme we see the first appearance of the occupational therapist as a member of the hospital rehabilitation team. Large numbers of young women were trained in Boston during 1917 and came to France in 1918 to work in the splendidly equipped American military hospitals, which at the time of the Armistice provided over 250,000 beds. This gave a great impetus to a new profession in the hierarchy of the "rehabilitationists" of the future.

The Period between the Wars.—The elaborate and highly organized rehabilitation departments of the wartime orthopaedic centres were carried over into peacetime and flourished during the period of greatest activity of the Ministry of Pensions. The great Shepherd's Bush Hospital, once the Mecca of surgeons from all parts of the Empire, ultimately reverted to its old functions as a general hospital under a Board of Guardians. The curative workshops, alas! were dismantled. In the early years after the war it was found that the planned rehabilitation day with its disciplined programme could not be transplanted in its entirety to civilian hospitals. In any case, both accommodation and equipment were lacking. Remedial measures, however, were provided in plenty by the rapid development and expansion of massage departments in hospitals where no such developments had existed before. Occupational therapy in Great Britain was fostered mainly in the mental hospitals.

Rehabilitation in its modern guise came back into the picture during the period 1935–9, stimulated by the publication of the findings of (1) the Fracture Committee of the B.M.A. (1935); and (2) the Interdepartmental Committee of the Ministry of Health and Home Office on Accidents (1939). These reports found not only that there was a need for organized fracture or accident services in all large hospitals, but that after such hospital departments had made their maximal contribution to the functional recovery of the injured man or woman, in a certain proportion of cases something more would be required. For this final act of reconditioning, or rehabilitation as it now came to be called, special residential centres outside the hospital appeared to be necessary. During the present war, under the aegis of the Miners' Welfare Commission, a number of miners' rehabilitation centres have been established in England and Scotland, and are in full activity. More recently non-residential centres for dockers have been set up in the ports of Liverpool and Manchester. These "day centres" provide a full and varied programme of diversional and remedial pursuits and deal with the after-effects of illness as well as with accidents.

---

* An address given to the East Lancashire branch of the B.R.C.S. Officers' Training Course, Manchester, May 13, 1945.

Medical Rehabilitation To-day

We have now brought our story down to the present day. As the result of the experience gained during the five and a half years of the war which has so recently ended in Europe, we have become even more conscious of the significance of both *medical* and *social* or *industrial* rehabilitation. The whole conception has assumed a more dynamic form. But, as I have tried to show, rehabilitation is not a new idea. During the Second World War the hospital rehabilitation schemes developed by the Emergency Medical Service of the Ministry of Health, and by the hospitals of the fighting Services, have in essence reproduced the pattern of the military orthopaedic centres of the First World War. To see the full medical rehabilitation programme in action in an E.M.S. special centre is a stimulating and inspiring experience. Each patient has his day mapped out, and he goes from one department to another in accordance with his special needs. In such hospital rehabilitation departments, patients who are likely to regain full fighting or industrial capacity in a relatively short period can be submitted to strenuous types of reconditioning. But in order to witness the most powerful and intensive reconditioning programmes we must go outside the hospitals and visit an Army Convalescent Depot, an R.A.F. Rehabilitation Centre, or a Miners' Rehabilitation Centre. Here we can see the application of the supreme tests of fitness and agility.

What lessons have we learnt as a result of all this experience? How much of this pattern of intense and sustained activity can be applied to the sick and injured during in-patient treatment and convalescence in our hospitals in peacetime? The experience of the E.M.S. has emphasized two facts: first, that rehabilitation facilities exist not only for the injured but also for the sick; and, secondly, that for all patients in bed, unless acutely ill, a suitable rehabilitation programme can and should be instituted in the early days of the disease or injury. The basis of such an active regime is movement, as opposed to rest and relaxation; movement prescribed in the form of individual exercises or in simple "class" exercise under the direction of the physiotherapist or ward sister. The occupational therapist is also to be introduced at an early stage, and the most suitable bedside craft or diversion chosen for each individual patient. For patients whose illness or disability necessitates a long stay in hospital such active measures have a special value in preventing certain complications to which bed-fast patients have always been liable. This was known to Hippocrates. The large-scale experiment of the Ministry of Health in *medical* rehabilitation, conducted mainly in *ad hoc* hospitals, has stimulated the civilian hospitals to review and overhaul their existing facilities. In the departments of physiotherapy and in the training of physiotherapy students, greater emphasis is now laid on the use of active rather than passive methods of treatment. There is also a move to set up separate rehabilitation huts or departments where a full day programme can be offered to selected groups of patients whose occupation or disability calls for such special attention. Hospitals are also becoming more aware of the need for a more direct link with the stage of social and industrial rehabilitation. Hospitals which have been slow to encourage an almoner service, or have misused the almoner for the purpose of assessing and collecting contributions, are beginning to realize the necessity for the attachment of social workers to all the main clinical departments. Furthermore, they are learning to open their doors to the entry of Ministry social officers from the outside. This is all to the good; it represents a step forward in the fusion of curative medicine and social services in a co-ordinated scheme for the benefit of the hospital patient. Such are the immediate lessons to be learnt from the experience of the last few years.

There is now another side of the picture to be considered. We must realize that we are still looking at medical rehabilitation through the spectacles of total war, with its increase in tempo and intense stress on the minds and bodies of men and women. The urge has been to return the man (or woman) to the fighting line or workshop at the earliest possible moment and to cut down periods of incapacity by a degree which can be demonstrated to all by the figures of the statistician. Medical rehabilitation, in our present mood, has come to mean an intense tightening up—a hardening process, with speed as its prime mover. We may well ask ourselves whether there is no longer a place for rest and relaxation during and following illness or accident. A regime consciously or unconsciously designed during war to provide for the needs of fit young men or women, at a time when there is unity of purpose in the nation, may not of necessity be suitable for a society which, in Great Britain in ten years, will present an increasing proportion of elderly folk who must continue to work. To cut down, by the most intensive form of rehabilitation, the incapacity period for a particular illness or accident by, say, 2.5 days may not in the future appeal to members of a society which comes to think of work, rest, and leisure in terms of human happiness, "the good life," rather than in terms of individual industrial output. This is not to say that the period of convalescence should not be better planned in the future; purposive activity remains the keynote of recovery. For, as Hippocrates taught, "exercise strengthens and inactivity wastes." But in any comprehensive rehabilitation plan there is a time and a place for both mental and bodily rest as well as action. I believe that there will still be room for the old-style convalescent home—the rest home—but equipped with facilities for diversion and recreation, to provide for a stage in recovery which precedes the final act of reconditioning. Less strenuous measures of rehabilitation will also be required by that large section of the community, mainly middle-aged, who are the victims of the various forms of chronic rheumatic disease.

It will thus be necessary, in the future planning of schemes of rehabilitation, to preserve that harmonious balance between rest and activity which is best calculated to restore the sick or injured man or woman to a state of maximum health and happiness.

EPSOM COLLEGE IN 1944-5

At the 92nd annual general meeting of Governors, held on June 22, Lord Leverhulme, the president, referred to the new Education Act and said that the good news that Epsom College and all other public schools in the country were safe in their independence at least for some years to come was a result of the patient work of the Governing Bodies Association, the Headmasters' Conference, and other bodies. The new Burnham Scale would affect salaries as a whole, but, as many felt that the new scale was not generous enough to graduates or to headmasters, most public schools would wish to pay more. A fair and reasonable post-war salaries scale at Epsom was now being considered. The fees, too, would have to be increased, because not only did they not cover the cost just before the war, but a heavy rise in expenses must occur when wartime restrictions were removed. Two events were imminent—namely, the College Centenary and the War Memorial.

Referring to the finances during 1944, Lord Leverhulme said that the small surplus on the school account would have been more by some £1,300 but for the V bombs, which caused the sending home of boys not taking public examinations two or three weeks before the end of the summer term, for which an allowance was made to parents. The numbers of boys during 1944–5 showed an increase of 15 over the preceding school year, and it was confidently hoped that the school would have its full complement of 500 boys in 1946. With regard to new benefactions, the president stressed the value of the bequest of the late Mr. J. W. Loader Cooper founding scholarships for sons of solicitors, and of the Eastes Trust, the income from which would go in the relief of doctors of either sex, less than 60 years of age, or widows, and also to educate children of medical practitioners.

FUTURE HOSPITAL SERVICES

PATTERN FOR LONDON AND SURROUNDING AREA

In 1941 the then Minister of Health announced his intention of ordering a survey of hospital services. For this purpose England and Wales was divided into ten areas, and the survey was conducted in each area by a team of two or three hospital experts. For London and its region Dr. A. M. H. Gray and Dr. Andrew Topping were appointed surveying officers, and the result of their work is now published in a massive Blue Book,[1] two-thirds of which is taken up with tables and analyses.

The area of this survey was roughly bounded by the line of the Chilterns to the north-west of London and the east and south coast from Essex to Dorset, comprising twelve counties or parts of counties, with, in 1938, a population of over 14 millions. In this area there are 390 voluntary hospitals, the hospitals of 25 major local authorities, and 130 isolation hospitals provided by minor authorities. In 1938—the last normal year—the voluntary hospitals in this area had 472,750 new in-patients, and the local authority hospitals a slightly larger number (476,507). Note is made of the patchwork of administrative arrangements and the irrelevance of administrative boundaries to the distribution and flow of hospital traffic, so that patients living within easy reach of a municipal hospital may be debarred from using it because the administrative boundary runs through the next street. Voluntary hospitals are, of course, free from this difficulty, but they have their own drawbacks—competitive development to meet the same need, friction instead of co-operation with other hospitals, and dispersal of resources instead of concentration into efficient units.

Voluntary Hospital Services

The surveying officers make three main criticisms of voluntary hospitals:

1. In their view there are no advantages attached to the custom of expecting the consultant and specialist to give his services without remuneration. The custom has resulted in unequal and unsatisfactory distribution of consultants and specialists. Only by the system of salaried part-time specialists can a service be provided adequately covering the whole area.

2. The large proportion of surgical cases dealt with at small "general practitioner" hospitals has the unfortunate result that surgery is often carried out by general practitioners whose skill and experience must necessarily be limited. In any case it is a diversion of this type of hospital from its proper function, which is the nursing under the care of their own general practitioner of medical and surgical cases which cannot properly be nursed at home.

3. The independent spirit of voluntary hospitals, their initiative and power of inspiring local loyalty are not always conducive to the maintenance of an efficient service. There have been examples of a tendency to adopt a course of action more likely to enhance the importance of individual hospitals than to produce the best facilities for the patient. The way in which some hospitals have undertaken the treatment of malignant cases by radiotherapy without either expert staff or the necessary ancillary facilities is mentioned as an example.

Local Authority Hospitals

Municipal hospitals also come in for some criticism, particularly as regards their methods of staffing. They are staffed by a medical superintendent whose duties are primarily administrative, by whole-time officers, and by visiting specialists who do not normally have charge of beds. The arrangement may have been satisfactory when comparatively little "acute" work was done, but it has ceased to be adequate. It is open to four main objections:

1. It tends to result in understaffing; the number of senior staff at municipal general hospitals is proportionately much lower than at similar voluntary hospitals.

2. The appointment of whole-time staff tends to divorce the work of the municipal hospitals from that of the voluntary hospitals and thus accentuates the division.

3. The visiting consultant, not having charge of beds, has little real stake or interest in the work of the hospital.

4. The system of paying comparatively low salaries to whole-time specialists and the highest salary to the medical superintendent has tended to drive clinicians of good standing into administrative posts as the only avenue of promotion.

Other points emphasized in connexion with municipal hospital services are the urgent need for further provision of consultative out-patient departments; the room for improvement in arrangements made for the diagnosis of patients before they are classified as "chronic," and for their care as long-stay cases; and the fact that local patriotism has in some districts produced the same tendency towards duplication of services and over-ambitious developments which has been noted in the voluntary hospitals.

It is added that co-operation between the two branches of the hospital service could with advantage be closer in most districts. Here and there it has reached a more advanced stage, and by the appointment of the same consulting staff in certain branches and a limited division of functions some voluntary and municipal hospitals are laying the foundations for a thoroughly co-ordinated service in the future.

Adequacy of Services

In the London voluntary hospitals in 1938 61% of the in-patients came from the county of London, 30% from the four adjoining counties (Middlesex, Essex, Kent, and Surrey), and 9% from further afield. It is noteworthy that in spite of the considerable development of municipal hospital services in London and of the fall of nearly 8% in the population of the county between 1931 and 1938, the number of Londoners treated in voluntary hospitals in London increased by nearly 5%. Again, in spite of the development of municipal hospital services in Middlesex and Surrey, and to a less extent in Essex and Kent, the number and proportion of non-Londoners treated in London voluntary hospitals rose by 15% during that same period, though that, of course, is partly a reflection of the great increase in the population of Outer London.

Before the war heavy pressure was experienced on general hospitals in London, especially south of the Thames; there was also general shortage of beds in Middlesex, at many places in Essex and Kent, and particular deficiencies in certain parts of Surrey. General practitioners in almost every area outside London testified to widespread difficulty in obtaining consultant and specialist services. As for pathology, except in London and the large towns, what is known as "postal pathology" was relied on, with little opportunity for consultation between pathologist and clinician.

The war, and especially the Emergency Hospital Scheme arising out of it, has had a marked effect on hospital services. It has helped the co-ordination of hospitals, the use of accommodation in the most advantageous manner, and the free transfer of patients. London since 1938 has sustained a net loss of 2,370 general hospital beds, but Middlesex has had a net gain of 1,365, and over the area covered by this survey the net gain has been 4,260, or, taking into account the beds in public assistance institutions and sanatoria, nearly 11,000. These should go a long way towards relieving deficiencies until major building becomes possible.

> "On the solid foundation provided by the pre-war hospitals, both voluntary and municipal, with their staffs and equipment, and by the help given by emergency developments, it should be possible when the war ends to introduce a service better than that of 1938 in all parts of our survey area."

It is often suggested that, with modern transport, hospitals should be located outside towns, in more healthy surroundings. The surveying officers do not think that suggestion altogether well founded. Town hospitals may have pleasant surroundings if planning is adequate, and both for the out-patient and for the in-patient and his visitors ease of access is as important as suburban air. The "acute" general hospital must be as nearly as possible central to the population it serves, and this applies even more strongly to the teaching hospital.

Medical Staffing and Hospital Linkage

The surveying officers point out that the problem of making hospital facilities available in every area is largely a problem of staff—not of building. The circumstance which has prevented the development of hospitals staffed by specialists in Greater London is the impossibility of remunerative private practice away from Central London. They hold, therefore, that specialists should be adequately paid for their hospital work, whether at a voluntary or municipal hospital, and whether on a whole-time or part-time basis. They declare against payment by sessional fees. Such a method is satisfactory neither to the specialist nor to the hospital. It exposes the former to the charge of trying to increase his income by rendering unnecessary services, and tempts the latter to economize by calling for his services less frequently than it should.

---

[1] *Hospital Survey. The Hospital Services of London and the Surrounding Area.* 1945. London: H.M. Stationery Office. (10s. net.)

In urging a common specialist staff as a link between voluntary and municipal hospitals, the surveying officers are anxious that it should not be assumed that the specialist staff of undergraduate teaching hospitals will link up with large general hospitals at a distance. In their view this will be impracticable. Any linkage between the teaching and the outer hospitals must be sought in other ways—for example, by house appointments at the outer hospitals for graduates from the teaching hospitals.

It is recommended that the appointing bodies for the common specialist staff should be assisted by an expert medical advisory committee comprising representatives of the medical faculty of the university, of the branch of medicine concerned, and of the hospitals where the specialists will have to work. In municipal hospitals it is considered that the salaries payable to whole-time senior members of the clinical staff should be little, if at all, lower than that of the medical superintendent, and the latter, whose title might be changed to "senior resident medical officer" or "hospital superintendent," should be engaged on administrative duties only.

Concentration of Services

This survey sets out the desirable provision in terms of beds and medical staff for a district hospital (that is, a general hospital, staffed by specialists and assistants, and providing for all normal types of "acute" work, both out-patient and in-patient) and for a special centre (an in-patient unit for specialties the exercise of which necessitates a high degree of concentration of staff or equipment in order to produce maximum efficiency). It is considered that maternity accommodation should be provided, wherever possible, in a unit associated with a general hospital. The provision for cases of infectious disease by means of small independent isolation hospitals is regarded as an anachronism. The solution is believed to lie in one of two directions—the provision of larger independent hospitals or of fever units in association with general hospitals. Beds for the chronic sick should also be provided in association with a general hospital, preferably as a separate block in the same curtilage.

In local (cottage) hospitals patients should be under the care of their own general practitioner, and it is thought essential that every practitioner in the locality should be able freely to secure the admission of his patients and to attend them. The hospital should, however, be visited regularly by the specialist staff of the district hospital with which it is associated.

> "It is one of the great advantages of the smaller voluntary hospital in the past that it has provided a link between the general practitioner and the hospital service and a meeting-place for discussion and consultation between practitioners."

Short-term and Long-term Proposals

A large number of recommendations are made for the building or extension of hospitals, but a distinction is drawn between short-term proposals, which can be put into effect in the immediate post-war period, and long-term ones which may reasonably be spread over the next twenty or thirty years in the light of present knowledge and probable change. In some areas there is pressing need for new buildings, for which hutted accommodation might for the present serve, and in almost all areas an even more pressing need for specialist staff. The key to the problem is once again the decentralization of specialists from London and their appointment at the principal hospitals—the so-called district hospitals—in the surrounding area. So far as geographical and other circumstances permit, two or three major hospitals should be grouped for the part-time employment of specialists.

The building recommendations may be briefly summarized as follows:

County of London.—Except in South London, where two new hospitals (at Tooting and Sydenham) are needed, the problem is one of co-ordination, with contraction rather than expansion. Teaching hospitals should remain in Central London, except Charing Cross, which might migrate to Harrow, and St. George's, to South-West London. Ultimate migration of the Royal Free by union with some other centre, such as the Royal Northern, should be borne in mind. Special hospitals should be reduced in number and grouped so far as possible around the University, sharing certain common services. It is suggested that a large site should be reserved in the university precincts in Bloomsbury. Here, among others, a new hospital for dermatology and a new hospital for urology should be established. St. Thomas's should be reconstructed and King's College extended.

Middlesex.—New district hospitals at Harrow (which might be the new Charing Cross), Enfield, and to the north of Golders Green; extensions at Ealing, rebuilding at Hillingdon, and new out-patient departments at West Middlesex and Staines.

Kent.—New hospitals in the Gillingham, Folkestone–Dover, and Bexley areas, and extensions at Canterbury.

Surrey.—New hospitals in Coulsdon–Purley and Woking, rebuilding and development at Kingston, Epsom, and Croydon.

Essex.—New hospitals at South Ilford–North Barking, Wanstead, West Ham, and Colchester.

Sussex.—Additional beds in the Worthing–Shoreham district.

Hertfordshire.—New hospital or extensions at Watford, and within a short time at St. Albans.

Bedfordshire.—Extensions at Luton and Bedford.

Hampshire, Dorset, and Isle of Wight.—New hospital at Aldershot, extensions at Portsmouth, Southampton, and Newport (I.O.W.), and extensions or new hospital at Weymouth.

Special Centre Services

Apart from special cases, an example of which is an orthopaedic hospital or a radiotherapy unit for cancer, no sufficient reason is found for special hospitals, apart from the requirements of teaching or research. The recommendations, however, propose certain special centre services, one such service being tuberculosis. In the past there has been a marked shortage of accommodation for this purpose, and some of the existing units are poor and obsolete. Nevertheless, if the best use is made of wartime extensions it should be possible to go far towards remedying the deficiencies, at least temporarily. For orthopaedics it is considered that each district hospital—or one hospital within the district hospital group—should provide a unit for fractures or traumatic surgery. Four rehabilitation centres are suggested: the Northern (L.C.C.) Hospital, Winchmore Hill; Mount Vernon Hospital, Northwood; Queen Mary's Hospital, Sidcup, and Orpington Hospital. The extent to which these centres are needed and the best method of organizing them can be decided only in the light of experience.

Some outstanding proposals are made concerning radiotherapy centres. An efficient centre is believed to require a population of about two millions as its constituency if uneconomical dispersal of skilled staff and costly equipment are to be avoided. At convenient points there should be hospitals fully staffed and equipped to provide treatment by radium and deep *x* rays, and outside these centres the treatment of malignant disease by these methods should not be undertaken at any hospital, large or small, general or special. The staff of the centre should visit all the district and subdistrict hospitals of the area for consultation on diagnosis and treatment as part of the cancer service.

According to this survey there are only two places in the region to which radiotherapy centres can reasonably be allocated—namely, London and Southampton. There is proposed accordingly a concentration of facilities in six grouped hospitals in London, each group serving a population of from 1½ to 2 millions, and, for Hampshire, Dorset, the Isle of Wight, and a part of Wiltshire, a centre based on the South Hants and Southampton Hospital, serving a population of 1½ millions. The six London centres would be the following:

1. Middlesex, University College, Marie Curie, and Mount Vernon Hospitals, the last two perhaps amalgamating.
2. St. Bartholomew's.
3. London Hospital.
4. Guy's, Lambeth, and St. Thomas's, with Lambeth, perhaps, playing the principal part.
5. Westminster and Royal Cancer Hospitals, with additional beds in the adjoining St. Luke's (L.C.C.) Hospital.
6. Hammersmith Hospital.

Within each group constituting a centre the radiotherapeutic, surgical, medical, and other staff engaged in cancer treatment would be common to all the hospitals.

Dr. Gray and Dr. Topping have liberally interpreted their reference to survey the hospitals and advise the Minister what area would properly be served by a hospital system centred on

London; and what modifications or enlargements of existing hospital facilities would be necessary or desirable to give effect to the general principles of post-war policy which the Minister announced in Parliament in October, 1941. Very much that they have to say applies not to the London region only but to the whole country; but that does not make it less useful or pertinent.

ROYAL SOCIETY OF MEDICINE

PRESENTATION OF AWARDS

At the annual meeting of Fellows of the Royal Society of Medicine on July 3 the gold medal of the Society was presented to Brig. Sir Lionel Whitby, and scrolls of honorary fellowship to certain distinguished persons in the medical services of the British and Allied Forces. The meeting was preceded by a luncheon at which the recipients of the honours, the Belgian and Norwegian Ambassadors, and the Presidents of the Royal College of Physicians, the Royal College of Obstetricians and Gynaecologists, and the British Medical Association, were present.

The President of the Society, Surg. Rear-Adml. Gordon-Taylor, in making the presentations, addressed the Czech, Norwegian, and Belgian recipients each in his own tongue. Of Sir Lionel Whitby he said that it was primarily for his distinguished work on the problems of wound shock and transfusion of blood that the gold medal was awarded. Of the numerous factors which had contributed to the lowering of mortality among those damaged by enemy action, despite the increased gravity of the injuries sustained, blood transfusion indubitably had played the most important role. He described Sir Lionel Whitby as "the greatest vampire the world has known."

The first of the awards of honorary fellowship was made to Gen. Frantisek Langer, D.G.M.S., Czech Army. The award was accepted on his behalf by Col. Mahler, who explained that Gen. Langer had now returned to Czechoslovakia. He took occasion to express the sincere thanks of his compatriots for the friendship with which they had been received in this country. Dr. Karl Evang, D.G., Norwegian Public Health Services, was the next recipient. The President said that the award was made in virtue of his distinguished services to free medicine and in the hope that this small gesture would help him in his work of rehabilitation in Norway. Dr. Evang expressed thanks especially for the way in which the Royal Society of Medicine had opened its doors and made its facilities available to foreign visitors. He added that Norwegian medical science before the war, though it had turned partly to this country and the United States, had also looked to the south, to Austria and Germany. There would now be a radical change, and in future more Norwegian medical men would be knocking at the British door. The last of the Allied recipients was Col. Gallemaerts, D.G.M.S., Belgian Army, who accepted the award as a compliment not to himself alone but to his fellow Belgians.

It had been intended to confer the honorary fellowship on Gen. Smirnov, head of the medical service of the Red Army, but the President explained that although letters and cables had been sent to him in Moscow, telling him of his nomination, they must have miscarried, for no reply had been received. This academic award could not be received by any Russian representative on his behalf until certain Governmental formalities were completed. If these difficulties could be smoothed over there was a hope that they might yet one day see the distinguished D.G.M.S. of the famous Red Army among them.

The honorary fellowship was next conferred on Surg. Vice-Adml. Sir Sheldon Dudley, D.G.M.S., R.N., for his wide and distinguished work in the field of pathology and epidemiology and also as Director-General of his great Service; on Lieut.-Gen. Sir Alexander Hood, D.G.A.M.S., an outstanding feature of whose reign of office, said the President, was the harmonious relation between himself and his staff and those drawn into the Service from civilian ranks; on Air Marshal Sir Harold Whittingham, D.G.M.S., R.A.F., whose many great contributions to pathology, clinical medicine, and especially the medical problems connected with aviation, were acknowledged; and on Sir Francis Fraser, D.G., E.M.S., who had earned the high regard of the immense service which he had controlled.

At the ensuing business meeting of the Society the annual report of the Council was adopted. This showed a total membership of 7,390, a gain of 609 on the year. Reference was made to the successful series of Inter-Allied Conferences on War Medicine held throughout the session. The Society had made all medical men in the Allied Forces welcome to its meetings and as guests in its library. It was mentioned that the formation of a Section of Endocrinology was under discussion by the Council. An Oestrogen Committee had also been set up following a meeting of the Section of Radiology on the treatment of cases of cancer of the breast with stilboestrol; the investigation undertaken by the committee, with Prof. E. C. Dodds as chairman, had been considerably extended.

ROYAL MEDICAL BENEVOLENT FUND

The annual general meeting of the Royal Medical Benevolent Fund was held at the Medical Society of London on June 20. The death of the late president, Sir Thomas Barlow, was recorded with great regret, and many references were made to his untiring work for and sympathy with the Fund. Sir Arnold Lawson, K.B.E., F.R.C.S., was elected as president, and Dr. C. Luther Batteson as honorary treasurer and Mr. R. M. Handfield-Jones, *M.C.*, M.S., as honorary secretary. The honorary auditors, Messrs. Deloitte, Plender, Griffiths and Co., were re-elected for the ensuing year.

The resignation of Dr. C. O. Hawthorne, who for many years served as chairman of the Case Committee, was received with very great regret, and as a token of the members' appreciation and his great service he was elected a vice-president of the Fund together with Dr. W. P. S. Branson, C.B.E., who had served on the committee for many years, and Mr. F. J. Strong Heaney, F.R.C.S., who rendered valuable services as honorary local secretary in Liverpool for many years.

The balance sheet and accounts of the Royal Medical Benevolent Fund and of the Ladies' Guild of the Royal Medical Benevolent Fund were adopted. A vote of thanks was proposed from the chair to the *British Medical Journal* for the help given to the Fund during the past year, special reference being made to the generous support afforded by the *Journal* to the Christmas Gift Appeal.

ORDER OF ST. JOHN

The following medical promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem have been announced:

As Knights, Surg. Rear-Admiral C. P. G. Wakeley, C.B., Air Marshal Sir Harold E. Whittingham, K.C.B., K.B.E., K.H.P., and Dr. J. M. Wilson. *As Commanders (Brothers)*, Major-Gens. Sir Ernest M. Cowell, K.B.E., C.B., D.S.O., K.H.S., and Sir Percy S. Tomlinson, K.B.E., C.B., D.S.O., Lieut.-Col. D. C. L. Fitzwilliams, C.M.G., and Drs. D. L. Beath, O.B.E., E. Lewys-Lloyd, and T. H. Leggett. *As Officers (Brothers)*, Col. D. Clyde, C.I.E., Lieut.-Col. L. K. Ledger, O.B.E., and Major G. B. Thomas, I.M.S., Capt. G. F. Shepherd, Surg. Capt. A. McCallum, O.B.E., V.D., Surg. Cmdrs. J. S. Elliott, A. E. Ginn, and C. H. Birt, Air Cdre. D. McLaren, Group Capt. J. Kyle, and Drs. L. D. Porteous, J. B. McKay, W. Mailer, C. V. Nicoll, A. P. Spark, S. McClure, C. H. Buckley, and J. C. Ashton. *As Serving Brothers*, Lieut.-Cols. T. F. Briggs, and F. A. Bevan, T.D., R.A.M.C., Messrs. D. A. Davies, F.R.C.S., J. B. Dobson, F.R.C.S., and K. Watson, F.R.C.S.Ed., and Drs. J. K. Thomas, G. F. Mitchell, J. H. Kahn, D. F. Barrett, W. C. Saunders, W. H. Shilvock, W. J. F. Craig, H. S. Savage, E. L. Butler, T. R. Hunter, E. M. Dearn, W. Radcliffe, C. C. H. Cuff, O.B.E., S. F. Jayawardene, W. B. Winckworth, W. W. Ballardie, J. Fenton, G. R. Bruce, O.B.E., J. W. Pickard, W. A. F. Hurst, J. N. Hudson, D. G. Lloyd, R. G. Bingham, C. T. Scott, J. S. Briggs, J. P. Davies, R. W. Edwards, J. A. Evans, H. Middleton, M.C., and W. G. Saunders. *As Serving Sisters*, Drs. Ethel Browell and (Mrs.) Ada V. V. Parkes.

TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council announces that preliminary arrangements have been made for the resumption of Rockefeller Medical Fellowships, to be provided from a fund entrusted to the Council by the Rockefeller Foundation of New York. These fellowships are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. It is hoped it may be possible to make a limited number of awards during the academic year 1945–6, depending on the availability of candidates and facilities for travelling.

MATERNITY AND CHILD WELFARE

NATIONAL CONFERENCE IN LONDON

A National Conference on Maternity and Child Welfare was held at Friends House, London, on June 28 and 29. It was arranged by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality, and was attended by about one thousand delegates—the largest number ever recorded.

In opening the conference Dr. JANE H. TURNBULL, chairman of the National Association, recalled the fact that the first conference of the kind was held in 1906, and was presided over by the late Mr. John Burns, then President of the Local Government Board. Since 1913 there had been a conference every year, with the exception of two years in each of the great wars. The conference represented a valuable union between Government and municipal effort on the one hand and the efforts of voluntary organizations on the other. She went on to refer to the inevitable modification of maternity and child welfare services which would come about in connexion with the proposed National Health Service. Any such modification, however, should develop and not destroy the admirable organization for maternity and child care exemplified in the schemes of the best local authorities. Progressive research was needed in the nutrition of mother and child, and more attention to education in mothercraft and fathercraft, to the care of the homeless child, and to the standards of staffing in institutions.

Minister of Health's Survey

The MINISTER OF HEALTH (Mr. Henry Willink), in a presidential address to the conference, gave a survey of the achievements of maternity and child welfare during the war. He began with a reference to the improvement in vital statistics:

	1940	1944
Birth rate per 1,000 population	14.6	18
Infant mortality per 1,000 births	56.7	46
Stillbirths " " "	36	28
Neonatal deaths " " "	29.6	24.5*
Maternal mortality " " "	2.61	1.94*

* Provisional figures.

Mr. Willink said that in the middle of a General Election he would not be expected to make any startling announcement on policy; he would say only a little on projects in hand. Among past achievements he referred to the emergency maternity homes and ante-natal and post-natal hostels for expectant mothers from the target areas. Within a few months from the start of this effort 260 emergency homes, with about 3,700 lying-in beds, were opened, in which 75,000 confinements took place in the year. Many of these homes had now been taken over by the major welfare authorities or had been closed if no longer suitable, but many others would have to remain open for some months yet, until more of the maternity accommodation which had been destroyed by bombing could be restored. Along with these maternity homes had been built up a system of residential nurseries for "under-fives" who had been deprived of parental care. The third great wartime experiment in maternity and child welfare was the provision of day nurseries for the children of war workers—1,500 of them, with places for between 70,000 and 75,000 children.

The campaign for diphtheria immunization had been actively continued, and the results were good. Not only was the death rate from diphtheria falling but there was a striking difference in incidence, and a still more marked difference in death rate, between protected and unprotected children. The necessary standard of immunization had not yet been reached if the disease was to be controlled, and he hoped there would be no slackening of effort. Two of the subcommittees of his valuable Advisory Committee on Mothers and Young Children had recently completed their work. The result was, first, a leaflet on rickets, shortly to be published by his Department; and, secondly, a report on arrangements for the provision and supervision of foster-mothers.

As for the future, there was need for increased maternity accommodation. During the war 5,500 new beds had been put into commission in maternity homes, but the proportion of institutional confinements had increased from about one-third to one-half of the total, and the demand for accommodation had been by no means satisfied. The Government idea was that all maternity units should be planned as integral parts of the pattern of hospital accommodation over a wide area, even greater than the area of a single local authority. It was desired to associate maternity units with large general hospitals, so far as geographical considerations allowed, in order to make readily available the services of consultants and the use of special equipment. It was also proposed to extend the training of health visitors from six months to nine months. He alluded finally to the Royal Commission on Population now sitting, pointing out that it was a new thing in history that the growth or decline of a population now depended on the deliberate judgment of the people themselves—a momentous and perplexing problem for Western civilization.

Nutrition of Expectant Mothers

The first discussion at the conference was on nutrition. It was opened by Prof. S. J. COWELL, who stressed the importance of a sufficiency of protective foods, during both pregnancy and lactation, and made it clear that in practice the aim of preventing deficiencies was not as yet fully realized. Dr. MARGARET WRIGHT addressed herself particularly to vitamin K, the coagulation vitamin, mainly provided by vegetables, the intake of which remained at the discretion of the expectant and nursing mother. A regular intake of leafy vegetables, tomatoes, and liver might be expected to improve the dietary resources of vitamin K. One medical measure which might be responsible for diminishing the absorption of this vitamin was the general use of mineral oil in the form of liquid paraffin. This had been shown to reduce the absorption of carotene in animals, and it seemed uneconomic to take so much trouble over dietary provision and education of expectant mothers and at the same time encourage them to use a popular laxative which must in some measure minimize their efforts. She suggested that a revision of medical and nursing opinion on liquid paraffin was due. Miss R. M. SIMMONS, dietitian to Hammersmith Hospital, gave an interesting account of the ways in which expectant mothers and mothers of young children are taught to feed themselves and their offspring.

Unity of Services

A session presided over by Prof. J. M. MACKINTOSH was devoted to the question of unity of the maternity and child welfare services. The subject was introduced by Dr. NORA WATTIE, senior child welfare officer, Glasgow Corporation, who argued that as reproduction was a continuous physiological process from conception until the end of lactation it was logical that there should be a unified control of services which a mother needed; yet she pointed out that during this period of reproduction mothers might pass through several hands from one administration to another.

> "No one can be satisfied with the present set-up. For instance, in most areas the maternity and child welfare ante-natal clinics are not staffed by personnel who have a hospital connexion, and the medical staff very often after appointment no longer engage in obstetric practice. In my view the ante-natal clinics and the maternity beds should be administered as a single service in the health department, the clinics, whether held at the hospital or at the maternity and child welfare centre, being staffed by medical officers whose duties would include both clinic and hospital practice. . . . There are obvious advantages in having the maternity unit part of a general hospital sharing common services and facilities, but it should not be administered as such. The maternity unit should be regarded not so much as a hospital but as part of the cycle of childbearing—a normal physiological process. It is mainly for this very important reason that emphasis should be laid on the necessity for avoiding any administrative break in the continuous care of the mother during the expectant, lying-in, and post-natal stages. It follows, therefore, that indoor maternity provision should be administered as part of the general maternity service."

Dr. Wattie considered it disappointing that the conception of the health centre in the White Paper had been so unfavourably received, because, for large areas of population, such a development was just what was wanted. The joint centre would become the focal point for the persons engaged in the various aspects of the care and health of the child from birth to the end of school life. The same medical officer should look after the child from infancy up to school-leaving age, and the health visitor should carry out the same continuity of supervision.

The Midwives' View

Miss G. L. Reed, who spoke on behalf of the College of Midwives, said that midwives desired a closer unity in the services. For all domiciliary midwifery there should be access to specialist hospital services when and where necessary, but those services should not intrude so far on the normal as to minimize the position of the mother as a member of the family and a partner in the home. A large percentage of women would always need to be confined in hospital, but the encouragement of family unity should not be forgotten; and birth in people's own homes had been for many generations an underlying factor of British midwifery.

Dr. Alan Moncrieff put forward the views of the British Paediatric Association on certain points. The association, he said, disliked the idea that ante-natal work should be divorced from the actual conduct and supervision of labour and the puerperium. He hoped that in future it would no longer be true, as it was in London, that ante-natal work was largely undertaken by the borough councils and the actual midwifery by the county council. If medical officers were to be responsible for seeing the mother right through they would clearly have to be specialists in their subject. Similarly in the case of the child, it was hoped that medical officers would undertake the care of the newborn, of the older infant and young child, and of the school child, so that there was a continuity right through childhood; and here again specialization appeared to be necessary.

> "If general practitioners are to do more of the health work among children, as the White Paper suggested, they too must be closely linked with the appropriate hospital services. A general practitioner doing infant welfare clinic work, for example, should also be on the staff as a clinical assistant of the nearest paediatric department. The division in the past between hospital paediatricians and child health medical officers has been unfortunate, and a unity in this part of the work seems to me of very much greater importance for the health of the community than preserving a unity at the level of the medical officer between maternity and child welfare. The training of medical officers of health in the future must surely allow for early specialization in one or other of these major branches."

One delegate from the floor of the hall protested against high maternity-home charges, which she declared to be a "dreadful scandal."

Day Nurseries

A discussion on the State and the parent in relation to the child was noteworthy for an attack by the Archbishop of Westminster (Dr. Griffin) on day nurseries. Efforts to tempt women to leave the care of their little ones to professionals were, he said, both harmful and unnecessary in normal circumstances. Money spent on day nurseries had better be spent in consolidating home life. Dr. Leslie Housden tilted at the idea of Francis Bacon, repeated in modern times, that the best works and of greatest merit for the public have proceeded from unmarried or childless men. Well, Shakespeare and Milton each had four children; Bach had twenty; Charles Darwin was survived by seven children; Mohammed had six, and the founder of the Salvation Army had eight. The happy family was not a drag but an inspiration. Dr. Grantly Dick Read made an eloquent plea for the teaching of parenthood and the spread of a more general knowledge of the advances in obstetric science so that fear of childbirth would cease.

The Lancashire County Council was among the first to provide a mass radiography unit, and at the beginning of this year the County Tuberculosis Committee presented a report of the first three surveys, ending on June 7, 1944. The surveys were made on (a) the staff of a county mental hospital, (b) employees of a large industrial undertaking, and certain allied groups; and (c) employees of a Royal Ordnance Factory. According to the report made by the County Central Tuberculosis Officer, Dr. Lissant Cox, 10,730 miniatures were taken, and 842 cases were submitted to full-sized radiography. No abnormalities were found in 93%; active pulmonary tuberculosis was found in 36 cases, and cardiovascular lesions were detected in 62. No diagnosis was made on the miniature film alone. Twelve of the 36 pulmonary cases had a positive sputum. Expressed in another way, the pulmonary cases represent 3.3 per thousand examinations, and the sputum-positive cases 1.1 per thousand.

Reports of Societies

URINARY BILHARZIASIS

Some surgical aspects of urinary bilharziasis were discussed by Mr. R. Ogier Ward at a meeting of the Section of Urology of the Royal Society of Medicine on June 28, Mr. McG. Loughnane presiding.

Mr. Ogier Ward said that patients with symptoms of this disease, typical or obscure, might be expected to make their appearance in hospitals in this country during the years immediately ahead, for British troops had served in territories where bilharziasis was always present and many had been infected. A. J. Renoult, the French surgeon of Napoleon's time, reported the condition as occurring mainly among cavalry, the result of excessive sweating, forced marches, and riding horses *vif et fougueux*. During the Boer War 625 cases were recorded, and a few were found among soldiers returned to England. In the first European war there were also many cases.

He next discussed the three main species of the bilharzia or schistosoma parasite: *S. haematobium*, the cause of the genito-urinary disease under consideration; *S. mansoni*, the cause of Egyptian splenomegaly and intestinal bilharziasis; and *S. japonicum*, the cause of eastern bilharziasis, a variety affecting chiefly the liver and spleen and confined to the territories bordering the western shores of the Pacific. The distribution of *S. haematobium* in Africa included the British territories of Sierra Leone, Gold Coast, and Nigeria, and all the north coast. There were a few places in Arabia and Iraq. As for the east and south of the continent, it was said to predominate in those territories whose waters drained into the Indian Ocean—e.g., the Zambesi. Most of the research on the parasite had been carried out in Egypt, an ideal country for its cycle. The disease was shown to have existed there since the twentieth dynasty (1250–1000 B.C.). Ruffer, in 1910, taking six mummies of that dynasty, soaked some of their organs in a solution containing glycerin, and on cutting microscopical sections found in two of them the terminal spined ova in the straight renal tubes.

In recent years the disease had assumed serious proportions in Egypt. In 1939 it was estimated by Scott, a director in the public health department of the Egyptian Government, as a result of 40,000 examinations, that half the population in the lowest and widest part of the delta harboured this parasite, very large numbers also being infected with the *S. mansoni*. The peculiar methods of agriculture in Egypt subjected the fellahin to constant and heavy reinfection. In other lands the disease did not commonly give rise to the advanced pathological conditions with which Egyptian surgeons were familiar.

Diagnostic Investigations

The most general method of making a diagnosis of urinary bilharziasis was to examine the last few drops of urine passed. Until cystitis occurred—and that was late in the disease—the urine, except for the last few drops, was clean to the naked eye. A solitary examination of the urine for ova was a quite unreliable test, for ova were not continuously released from the lesions of the mucosa. Five consecutive morning specimens, the last few drops of urine being collected and centrifuged, would in about 85% of cases show either ova or red blood cells. Even in the absence of these the continual presence of pus or albumin meant that a diagnosis of bilharziasis might be made until it was disproved. Cystoscopy was the most accurate method of diagnosis in all active phases, and should never be omitted in a suspected case in which no ova were found. Patches of congestion, most commonly in the trigonal region, were the earliest abnormality seen in the bladder mucosa, but these had no characteristics which would enable a certain diagnosis to be made. Later stages were specific. The first was the appearance of bilharzial tubercles, similar to the tubercles due to Koch's bacillus, with occasional congestion of the area of mucosa around a collection of them. An intense invasion by ova often caused very marked oedema. Bilharzial nodules were larger than tubercles, more permanent, and greyer, and were commonly met with in chronically infected bladders.

Mr. Ogier Ward went on to discuss the different ways in which bilharziasis of the bladder might develop from the earliest stages. Live ova from an infected area of the bladder might work their way through the mucosal covering and be shed into the urine, the healed area leaving no scar; or dead ova which had not been discharged might remain as tubercles for a long time. Calcification of bladder tissues around the ova was a permanent feature in severely infected, long-standing, and untreated cases, the calcification affecting chiefly the submucous layers of the bladder wall. Another stage was the development of bilharzial ulcer, usually single. When large numbers of ova collected in the submucous layer they might cause tumour-like bilharzial masses to project into the bladder. Tubercles were often seen on the surface of these masses. This condition could not be cured by antibilharzial treatment. Vesical papillomata due to bilharzia were common in Egypt, and it was said by Makar that bilharzial cancer was not rare in the Egyptian upper classes. Among the primitive populations of the Delta these malignant growths often produced great extensions and widespread metastases before the patients reached hospital, and in such cases pain, strangury, frequency, and bleeding were severe. Vesical calculi were met with in bilharziasis, and the ova had been found within the stones.

Until treatment with antimony sodium tartrate was introduced by McDonagh and Christopherson there was no known remedy for urinary bilharziasis. A number of other drugs had been tried, but tartar emetic remained the best, despite some unpleasant symptoms associated with its administration. The antimony first sterilized the generative apparatus of the female worms and ultimately destroyed them. In this country it was very unlikely that the latter complications—such as bladder growths and fistula—would be encountered, but examples of the earlier stages might well be seen. Officers and men of all three Services had been in the countries where this disease was endemic, and clearly some might bring it home with them. Urologists should know how to diagnose the early stages of bilharziasis; its later manifestations might remain chiefly a matter of general interest. One thing to be on the watch for was the insidious danger of ureteric obstruction when all signs of active prostatic infection had disappeared. It was necessary also to bear in mind that the worms, when their normal vein paths were obstructed, might find their way to the seminal vesicles, prostate, vas, epididymis, testis, or tunica vaginalis, and cause sclerosing changes in those organs.

Mr. **Clifford Morson** said that his first introduction to this disease occurred when he was house-surgeon to Sir John Bland-Sutton, who always believed that malignant disease was parasitic in origin. A case of cancer of the bladder was admitted, and in the course of investigation the ova of bilharzia were found, which seemed to confirm Bland-Sutton's theories. During the last war Mr. Morson had come into contact with cases of the disease while in Egypt, and what had impressed him was the complete indifference shown by the native to the passing of blood in the urine.

Sir **Philip Manson-Bahr** said that he had tackled bilharziasis in its origin in the field, together with his colleague Dr. N. H. Fairley. In 1916 men at the camp at Tel-el-Kebir on the eastern border of the Nile delta welcomed a chance of bathing in one of the irrigation canals, but they quickly began to suffer from a skin irritation, an urticarial rash, and an irregular pyrexia, and a number of cases of bilharziasis appeared. The condition was becoming much more prevalent than formerly in West Africa, and he did not doubt that cases would be found in this country among men returning from war service.

A representative of the War Office referred to an interesting observation lately made in India, where there were large numbers of West African troops near native villages and rice fields, and where it was quite certain that owing to the insanitary habits of the Africans the water would be infected. Yet although the ova were widely demonstrated in the African troops and among a proportion of the European officers, there was no infection of the Indian population. Some of the ova were collected from the troops and put in contact with local snails, but none of the snails became infected.

Mr. **Ogier Ward**, in reply, stressed the importance of thorough treatment with antimony. The course should amount to 30 grains, and it must be intensive lest a resistance to antimony was acquired.

Correspondence

Poliomyelitis in Malta

Sir,—As one who was connected with the poliomyelitis epidemic in Malta from its beginning may I be allowed to add a few comments to the very interesting paper by Prof. Seddon and Drs. Agius, Bartolo, and Coleiro (June 2, p. 759).

The authors, and your editorial comment (p. 773), give the impression that the generalized pains and the stiffness of the back, usually regarded as the first signs of this disease, were not a striking feature of the epidemic; that in fact they were conspicuous by their rarity. This view requires clarification. Of the 375 cases which occurred in Malta (as distinct from Gozo) I saw 210 in consultation at their homes before admission to hospital. On Jan. 2, 1943, I was appointed consulting physician to St. Luke's Hospital, and all the cases treated there were under my care until the acute phase of the epidemic was over, and Prof. Seddon arrived to take charge of what had now become an orthopaedic rather than a medical problem.

My experience was that two types of pain could be distinguished: an *initial* generalized hyperaesthesia due to meningeal irritation, and a *later* more localized pain sometimes associated with muscular spasm. The generalized pain was common and occurred in at least two-thirds of the cases. It usually preceded the paralysis and it affected limbs which were not subsequently affected. Here the diagnostic problem was to determine whether the child refused to move on account of the pain or on account of the muscular weakness. At the beginning of the epidemic scurvy was often suspected as a possible cause in view of the food situation at that time. The pain was not spontaneous and, left to itself, the child made no complaint. It only appeared when any attempt at movement was made by the examiner, and was especially marked when the movement involved the spine. Shaking the bed was also resented. This hyperaesthesia, elicited by examination, was not likely to be noticed by mothers—a fact which may explain why it was missed in the interrogation carried out two or three months after the event.

Stiffness of the back and of the neck, sometimes amounting to rigidity, was likewise a noticeable feature in the early stages. Coupled with a more or less marked Kernig's sign it frequently raised the suspicion of meningitis and necessitated an immediate lumbar puncture. In all the cases where this was carried out there was a high lymphocyte count without, however, a corresponding increase of proteins or a diminution of the chlorides.

With regard to the "spine" and the "tripod sign," it was difficult to obtain the co-operation of the young patients, even in those cases where the general condition permitted their being sat up. It must be emphasized that this pain and stiffness were very early signs, and had usually disappeared by the time the child was admitted to hospital.

The localized pains came later when the paralysis was already established. The first case of poliomyelitis to be diagnosed (D. C.) was referred to me as a case of rheumatism. The patient had had fever and generalized pain, *which her mother did not mention at first,* 7 days before, and now she complained of very severe pain in the shoulder and arm, which were, and have remained paralysed. The pain was eased as soon as the arm was immobilized in a raised and abducted position. I believe that these localized pains are of muscular or at least peripheral origin, and that they are due either to: (1) stretching of the paralysed muscles, (2) spasmodic contraction of surviving fibres, or (3) spasmodic contraction of unopposed antagonists. This type of pain was extremely rare among the patients admitted to hospital at an early stage, and I attribute this fact to the immediate, complete, and adequate immobilization, which was adopted as a routine when I took charge of the wards. I was anxious to give Sister Kenny's treatment a fair trial, but there was no opportunity to do so as pain and spasm were conspicuous by their absence. I can only remember one case (P. X., 10 months) where pain with spasm and flexion of both thighs persisted for more than one day after admission. The patient was given hot packs and massage, and the pain ceased when the limbs were gradually stretched out and splinted in an extended position. The child has made a complete recovery.

A number of patients developed pain while in hospital, and this was invariably traced to immobilization in a faulty position. In one particular case (C. B.) there was pain, spasmodic contraction, and tenderness of the adductors of the right thigh which was relieved as soon as the limb was put in abduction. From conversation with doctors who treated patients at home I understand that pain was a more frequent symptom, and I have no doubt that this was due to the less rigid insistence on immobilization.

It is now generally accepted that the virus of poliomyelitis does not attack the higher centres and that cerebral and cerebellar forms do not occur. This is borne out by my experience in this epidemic. The convulsions mentioned in the paper occurred either at the beginning of the infection and were probably due to the thermal disturbance, or towards the end, when they were caused by asphyxia. In the article under review reference is made to vertigo and to "typical cerebellar symptoms" in one case. It is extremely difficult to make children explain exactly what they feel, and giddiness is a common symptom in many fevers. The absence of nystagmus, noted by the authors, would seem to exclude a cerebellar origin.

With regard to treatment, no specific or convalescent serum was available at the outset of the epidemic. Later on, when a supply of specific serum was obtained, no suitable cases presented themselves. Sulphonamides were not employed, as they had already been proved to be ineffective. Treatment by potassium chlorate was considered, but, in view of the conflicting reports and its undoubted dangers, it was not used. Reliance was placed on immediate and complete immobilization of the whole body in the neutral position until the initial extensive paralysis had settled down. Thereafter immobilization was confined to the limbs and parts which showed any weakness and was adapted to the individual needs of each case. The splints were extremely primitive, but they were the only ones available at the moment. Many of them were knocked up by the house-physicians, and by myself, on account of the acute shortage of labour at that time and the rush of patients requiring attention. After the first fortnight the splints were taken off once daily and light massage was given to all the muscles.

The results seem to justify the procedures adopted. A mortality of 3.5% is not too high (average 5% to 20%) and a complete recovery rate of almost 40% compares favourably with 25% mentioned by Lovett. To me, however, the most satisfactory feature was the almost complete absence of contractures while the patients were under my care. As stated by the authors, a most painstaking review carried out in March and April "revealed only two cases in which there was very slight contracture"—in a thumb and in a toe, I believe. In the present state of our knowledge paralysis cannot be prevented once infection has occurred, nor can axonal regeneration be accelerated by the means at our disposal. Treatment in the early stages resolves itself into the prevention of contractures and deformities. That much, at least, was accomplished, albeit with very primitive means, by a rigid and unswerving adherence to the policy of immobilization.

It is unfortunate that no mention was made of the cases with bulbar involvement (36). The loss of speech, the salivation, and the dysphagia mentioned under different headings were due to this. These cases presented a difficult and distressing therapeutic problem. It was difficult to adapt the Drinker respirator to these young patients, and where this was done the benefit was only temporary. The best results were obtained by nursing in the head-down position and by giving large, sometimes heroic, doses of atropine.—I am, etc.,

Malta. J. E. Debono.

Transmission of Infection during Withdrawal of Blood

Sir,—In an article in the *Journal* of May 5 (p. 625) Dr. K. Mendelssohn and Prof. L. J. Witts, stimulated by the occurrence of an outbreak of homologous serum hepatitis in Droller's diabetic clinic, discussed the possibility of transmission of infection during the withdrawal of samples of blood. They came to the conclusion that after aspirating blood from a vein and then releasing the tourniquet before withdrawing the needle in order to prevent the formation of a haematoma, a negative pressure is produced and some of the blood in the syringe finds its way again into the circulation. They proved this by the following experiment: A burette, connected to a short length of rubber tubing, which in its turn was connected to a glass tube provided with a tap, was filled with water, and the apparatus fixed so that the rubber occupied the lowest position. A few drops of a concentrated solution of methylene blue were drawn into a syringe, the needle fitted, the rubber punctured in the direction of the tap, and some of the water drawn into the syringe. When the tap was opened—which corresponds to releasing the tourniquet—the fluid flowing from it was noticed to be tinged with the dye.

The experiment is simple and convincing; in fact it was repeated with identical results, but it was thought that it might be of some interest to do it again in what might be considered a somewhat more natural way—namely, by slightly contaminating the syringe with staphylococci instead of drawing methylene blue into it and by filling the burette with sterile broth, taking care to sterilize the whole apparatus. Otherwise everything else was done in the same way as above. The fluid flowing from the tap was received in a sterile flask and incubated at 37° C. for 24 hours. Growth of staphylococci appeared, but was rather scanty, showing that the inoculum was small. Another burette, full also of sterile broth, was used, the rubber was punctured, the fluid drawn as before, and the needle withdrawn without opening the tap. This corresponds to the withdrawal of the needle from the vein before removing the tourniquet. The whole apparatus was then incubated at 37° C. for 24 hours; no growth appeared.

One point is worth discussion: is it always necessary, in order to prevent the formation of a haematoma, to release the tourniquet before withdrawing the needle from the vein? I find that by applying firm pressure on the site of the puncture immediately the needle is withdrawn, at the same time removing the tourniquet, a haematoma hardly ever occurs. Nevertheless it would be, as the authors put it, penny wise and pound foolish to economize in sterile syringes.—I am, etc.,

Faculty of Medicine, Cairo. M. A. Gohar.

Excision of Patella

Sir,—A number of surgeons appear to regard removal of the patella not only as a highly satisfactory procedure but even as the operation of choice in fractures of this bone. On the other hand there are many who disagree strongly with this view and who resort to excision of the fractured patella only when severe comminution is present. That an excellent result may follow a properly conducted operation which includes excision of the bone none will deny. In too many cases, however, the result has been anything but perfect. Almost without exception I have found extension to be incomplete at the time of examination, usually within three or four months of the date of operation, even in those with an otherwise promising result. A common complaint is a feeling of insecurity on stairs and of stumbling on rough ground. Several of the results seen have been even more unsatisfactory, and in some the chances of a substantial improvement seemed small. Gross chronic swelling and thickening, marked limitation of both flexion and extension, and varying degrees of insecurity or unreliability of the joint have all been met with. One young woman, seen eighteen months after the operation, could negotiate stairs only with considerable risk of a fall; voluntary extension was incomplete by several degrees; flexion was complete but excessive. If the knee was allowed to flex beyond 35 degrees, while her weight was borne by the limb, she fell to the ground. A badly conducted operation, it will be said, and probably with truth, yet similar though less disastrous results are not so very uncommon. I am not denying excision is a sound procedure in badly comminuted fractures where it is impossible to restore the articular surface of the bone with anything approaching accuracy. The operation may also be indicated in a few carefully selected cases of osteo-arthritis.

My contention is that the patella is a useful bone, both as a protection to the joint and as an important part of the extensor apparatus, and, in the opinion of many besides myself, it should not be sacrificed, in whole or in part, when accurate suture is a possible alternative. Haxton (1945) has shown by experiment on the cadaver that "the patella improves the efficiency of knee extension in the more important extended position of the knee-joint. . . ."

Certain advantages are claimed for excision in place of suture. It is true that the period of immobilization can be reduced and recovery of flexion may be accelerated after excision, but not without risk to the power of extension. The sutured tissues should be given time to unite. Too early efforts to restore mobility have been known to result in disaster. The statement that arthritic changes on the front of the femur are entirely eliminated cannot be accepted; gross arthritic changes have occurred after removal of the bone. Published experimental work on animals suggests such changes are not only probable but inevitable. Bruce and Walmsley (1942) using rabbits found that degenerative changes in the articular cartilage of the patellar surface of the femur followed removal of the patella. Cohn (1944), in two groups of rabbits, adult and young, confirmed this, changes in the cartilage being found in every animal after patellectomy. When only the lower half of the bone had been removed similar degeneration of the cartilage was seen in every adult rabbit, but not in the immature animals. The fact that excision is in many cases an easier operation to perform than accurate suture must not be given undue weight. Which operation is favoured must surely depend chiefly on a comparison of the late results of the two procedures.

So far as I am aware, no considerable series of cases of excision of the patella has been published to support the contention made by Brooke in 1936 that this operation gives better results than suture in transverse fracture of the bone. There is, however, some evidence to the contrary to support our personal observations. An investigation, Brig. Bristow tells me, into the late results in soldiers who had sustained a fracture of the patella showed that of 27 cases treated by excision only 11% were returned to duty in category A, whereas of 31 cases treated by conservative measures, including suture, 80% were returned in category A. These figures may be objected to on the score that more detailed information is required before accepting them at their face value. No doubt those treated by excision included a larger proportion of the more severe types of fracture than the other group. Even if allowance be made for the first group's being the result of greater violence than the second, the figures must surely be regarded as impressive.

Friberg (1941), dealing with cases of chondromalacia and of "adverse sequence of fractures" treated by excision of the patella, reported that the function after excision of the bone was "complete" in 84%, yet no less than 43.8% of his 32 cases complained of insufficient strength and want of reliability and stumbling on rough ground. Seven cases of excision of the patella were followed up by Wass and Davies (1942), and in every single one the result was poor. Unsatisfactory results do, of course, occasionally follow suture, but I believe they are less frequent than after excision, and they could be further reduced in numbers were more attention paid to accurate suturing. As an indication of what can be achieved by skilful suture I may quote Scudder and Miller, who in 1916 published the results in a series of 38 cases. Extension was full in 94% and flexion was full in 60.5%. In 63% capacity for work was unaffected. Mr. F. W. Holdsworth tells me that in a recent follow-up of a small series of 10 cases dealt with by suture he found that in all but one extension was complete, while in only one was flexion less than 130 degrees, and in the exception it amounted to 90 degrees.

When it is decided the bone should be removed much depends on the way the operation is completed. Though it is possible in cases operated upon early to suture the extensor tendon to the ligamentum patellae, it is not really necessary to do this, and probably, as some believe, it is undesirable if the return of full flexion is not to be jeopardized. It is, however, essential that the hole left in the capsule should be reduced in size and prevented from gaping by stitches and not simply covered over with what has been stripped from the front of the bone. The statement that the extensor tendon passes entirely in front of the bone every surgeon knows to be inaccurate. With regard to the care usually taken to keep close to the bone when dissecting out the fragments, attention may be called to the fact that Friberg and also Wass and Davies found that the appearance of more than a trifling amount of calcification and ossification at the site of the patella was a distinct disadvantage and interfered with recovery of function.

Lastly there is the question of removal of the smaller fragment when the bone is broken into two unequal portions. On what grounds it is maintained by those who practise this that the chances of arthritis are materially diminished it is difficult to see. It seems a pity to throw away a fragment which affords the best possible hold for the stitches and which, at the lower pole, may be entirely devoid of cartilage.

I am convinced that the best advice one could give a young surgeon would be to learn to suture the fragments of a fractured patella with accuracy and not to resort to excision of the bone in the hope of getting a rapid result.—I am, etc.,

London, W.1. H. A. T. FAIRBANK.

The Edinburgh Outbreak of Smallpox, 1942

SIR,—Dr. A. L. Ferguson (June 30, p. 923), writing from South Africa, says: "The deaths from post-vaccinal encephalitis are regretted, but the deaths from smallpox would have been very much greater had not the population of Edinburgh been quickly and adequately protected by the measure of mass vaccination undertaken by the health authority." May I suggest that this assertion is really begging the whole question which it was the express object of my article to discuss. If, as I showed, the outbreak was definitely declining when the mass vaccination campaign was begun, what right has anyone to assert that the deaths would have been much greater?

Dr. Ferguson expresses surprise at the views I hold, but had he been living in this country he would doubtless have been aware of the great change which has taken place in medical opinion on the whole question of vaccination in relation to smallpox in recent years. Perhaps he will be even more surprised when he learns that the Minister of Health in this country, acting on the advice of his Medical Advisory Committee, proposes to terminate the present compulsory system of vaccination, and that the Council of the British Medical Association has agreed to the proposal. I can remember the time when any such proposal would have met with the very strongest opposition from the medical profession. To-day it is likely to meet with practically none, or, more probably, with a sigh of relief. Truly, *tempora mutantur, nos et mutamur in illis.*—I am, etc.,

Sweating Sickness and Picardy Sweat

SIR,—In your *Journal* for June 2 (p. 792) an inquirer asks if anything is known of the aetiology of sweating sickness which was common in the fifteenth and sixteenth centuries. Your commentator replied that "Hamer gave reasons for thinking that the sweats were epidemics of influenza." The evidence which exists makes this conclusion improbable. A case of this disease which occurred in a soldier in Picardy in 1918 was recorded by the late Dr. Michael Foster in the volume dedicated to Osler on his seventieth birthday (*Contributions to Medical and Biological Research*, 1, 52, Hoeber, New York, 1919). I discussed this case several times with Foster, and I also had a case under me in 14 Stationary Hospital for Infectious Diseases. Unfortunately the latter case was before Foster's, and the diagnosis was not made.

Sweating sickness first appeared as a new and previously unrecognized disease in 1485, when it attacked and caused a high mortality in the army of King Henry VII which had landed at Milford Haven from France. Between 1485 and 1551 there were at least four large epidemics in England. Caius in 1551 wrote the only medical account in the English language. After 1557 the disease completely vanished from England. Meanwhile it had appeared on the Continent, where it was known as *sudor anglicus*, but it subsequently disappeared for over 100 years.

From the beginning of the eighteenth century epidemics occurred in France of a disease which was called Picardy sweat or *suette miliare*. John Churchill the poet, whose death in 1764 is referred to by your correspondent, was taken ill at

Boulogne. Outbreaks with a high mortality occurred in 1840 and 1880. The last extensive epidemic was in 1906, when 6,000 persons were attacked in a few weeks in the Charentes area. This epidemic was studied by modern methods by a Commission under Chantemesse, but all investigations were negative.

The identity of Picardy sweat and *sudor anglicus* has often been discussed by French authors. The point at issue is the occurrence of an eruption in Picardy sweat, which Caius does not mention. Caius's "Boke" on sweating sickness is lengthy, but mostly consists of philosophical discourses and methods of preparation of herbal remedies. The clinical description is brief and applies to fulminant cases fatal within a few hours, in which type no eruption may develop. But the symptoms which Caius describes recur constantly almost word for word in the French literature of Picardy sweat, and were present in Foster's case. With regard to influenza, Chantemesse assured Foster that there was no resemblance between the two diseases. Certainly the two cases here referred to were not influenza. With plague it has no connexion. There is no substantial reason to doubt the identity of *sudor anglicus* and Picardy sweat.

The epidemics are explosive. They reach their maximum in a few days, maintain it for two or three weeks, tail off, and then completely leave the locality. The case mortality is very variable. In some epidemics the symptoms have been mild and there have been practically no deaths, but in many others the mortality has reached 30 or 40%. The epidemic of 1906 in Charente wiped out whole families in a few days. Deaths are almost confined to fulminant cases, and a fatal ending is rare after 48 hours. Rural areas are affected, and large cities are not attacked. It is not particularly an epidemic of warfare. The Commission of 1906 decided against direct contagion from person to person and attributed infection to the fleas of field mice.

As to the clinical features, the sweats are extraordinarily profuse and are independent of the height of the temperature or of its rise and fall. There are other symptoms which still exhibit the characters described by Caius: paroxysms of precordial pain with sensation of constriction in the chest and upper abdomen, feelings of suffocation and great distress, but there are no catarrhal symptoms and no abnormal signs in the lungs, heart, or cardiovascular system. There are curious sensations in the limbs and joints as of air moving—a description given by Caius, repeated by French authors, and accepted by Foster's patient. In the fulminant cases delirium and collapse rapidly develop, and death often occurs within a few hours of the onset of symptoms.

The eruption appears on the third or fourth day, or occasionally later. There are two factors—an erythema, and glistening white miliaria, which has led to the name *suette miliare* or miliary fever. The miliaria coalesce and form vesicles. The rash starts on the neck and trunk and spreads over the whole or most of the body. The rash has one curious characteristic: it stops at the wrist as if prevented from spreading further, and forms the miliary bracelet, which persists after the eruption has subsided elsewhere. This was present in both the cases in 1918. The eruption lasts a few days and is followed by desquamation. Convalescence is slow, but there are no sequelae.

Such is the disease which at one time was feared even above plague. We may bear in mind Foster's warning: "We should be unwise to regard it as necessarily a disease nearing extinction."—I am, etc.,

London, W.1. Henry Tidy.

March Fracture

Sir,—The frequency of march fracture (of the foot) and the line of treatment advocated by some are on occasion leading to this injury's being treated rather lightly, with the result that the number of cases coming to my notice where a march fracture has been diagnosed and the soldier kept on duty is increasing. That march fracture is a painful condition most will readily agree, and why the Service man with this disability should be kept going on an admittedly painful foot is difficult to determine. Whatever may be the structural defect which predisposes to the condition it must be admitted that the occurrence of the fracture does not remove it, and continued weight-bearing can do further damage to the foot itself, to say nothing of the effect of the continued pain.

Recently I have seen three cases of multiple march fracture in the same foot, and in all the history has been the same: either the first fracture was overlooked or, if it was diagnosed, it was disregarded and the man kept on his normal or slightly modified duty. In addition I have seen two bilateral cases with very similar histories. The case described below illustrates well the course of events, although this was the only case in which three fractures in one foot were found.

C. E., aged 18; service 6 months. Grade A1. After six weeks' training, towards the end of Dec., 1944, he developed a pain in the left foot during a route march. March fracture was diagnosed and *x*-ray examination confirmed a fracture of the third metatarsal. He was kept off duty for one week and then returned to training. After a week or two he had some further discomfort in the foot, which had never been entirely free from pain, but managed to carry on and complete this part of his course. At the beginning of May, 1945, he again had severe pain in the left foot when marching; he reported sick and was referred to hospital, where *x*-ray examination revealed this most interesting condition: third metatarsal, a healed fracture; fourth metatarsal, a partly healed fracture; second metatarsal, a recent fracture. *X*-ray examination of the right foot revealed no abnormality.

Whether march fracture when first discovered should be treated by simple relief from weight-bearing, by plaster fixation without weight-bearing, or by walking plaster, is probably a matter of personal preference, but all these methods do relieve the man's pain and would prevent multiple fractures; I believe that one or other of them should always be employed, and that keeping infantrymen on duty can hardly be justified.—I am, etc.,

Lancaster. Ian D. Kitchin.

An Occupational Therapy Department

Sir,—We have recently re-established at Maida Vale Hospital for Nervous Diseases a Department of Occupational Therapy, directed by a member of the Association of Occupational Therapists. This department is now open to receive out-patients from other hospitals, whether neurological, orthopaedic, or general, which lack occupational therapy facilities, or whose facilities are too far from the patients' homes for out-patient attendance. Private patients also are received. I think that the facilities offered by the department, being unusual in Central London, ought to be made known as widely as possible.

The department is well equipped for cases with physical and nervous disorders. Its facilities, when complete, will include evening sessions for those back at work, a children's room, and a homebound service for non-ambulant cases. The charge made is 2s. per patient per session, payable by the sending hospital, except private patients, who are reasonably assessed. Patients are received only on medical prescription, forms for which will be sent on application to the occupational therapist, who will also be glad to show the department to and to discuss possible scope with anyone interested, especially those who may not so far have utilized this treatment. Patients receiving occupational therapy may also, if desired, attend for speech therapy and other rehabilitation departments, which work in conjunction with the Department of Occupational Therapy.—I am, etc.,

Wilfred Harris,
London, W.9. Senior Physician, Maida Vale Hospital.

The Integration of Medicine

Sir,—The oration on the integration of medicine by Dr. F. M. R. Walshe, an abridged version of which was published in the *Journal* of May 26, appeared to concern itself more with the general foundations of scientific knowledge than with those simple acts of medical judgment which constitute the bulk of medical practice and in which all medical research culminates. Dr. Walshe deplores the lack of integration of scientific facts "beyond the basic elements of medicine as we know it"; are not just these basic elements at stake when we attempt to assess the scientific foundations of medicine?

The distinction between "liberal" and "useful" professions does indeed throw into relief the unique nature of the physician's work. Even if biological research were to conform to the high standard of integration demanded by Dr. Walshe, the fruits of research would still have to pass the test of clinical application in each individual patient. Research is invalidating, or at least questioning, an increasing number of "basic principles"; the scientist shrugs his shoulders at the physician who rests the heart by keeping the patient flat in bed, or applies warmth to every case of surgical shock. However well ordered the results of physiological research may be, however conscious the physiologist himself of the limitations of his science, doctors—everywhere and every day—practise their professions according to their lights.

By charging "clinical observation," "intuition and judgment," with the task of integrating medicine Dr. Walshe admits that medicine is not a science, nor must the so-called doctor–patient relationship be regarded as a mythical panacea, invoked whenever the doctor's status as scientist is in doubt. Semi-scientific activity of any kind does not derive sanction solely from the fact that it leads to the desired result from the patient's point of view. So far as human values and the sanctity of the individual are concerned, there is little to choose between the performance of controlled experiments on patients and the waving of the magician's wand. The doctor alone is not qualified to decide where liberal knowledge ends and useful knowledge begins. Around that decision revolves the practice of our profession. On that decision more than on anything else the integrating power of science must come to bear.

The material on which we work is human as we are ourselves. A weapon is thus placed in our hands of which the other sciences do not dispose. The will to live, so essential to the cure of any illness, could be transformed from an instinct into active co-operation by the patient if he were taken into the doctor's confidence more often. Many precepts of medical science could then be applied more rationally, many placebos dispensed with completely. Intellectual honesty of the doctor must naturally not be prejudicial to the patient's happiness or its object will be defeated; but the public must be made aware of the double orientation of the doctor if the fog that envelops us on our travels between bedside and laboratory is ever to lift. Ideally, the integration of medicine will take place when physicians have ceased to be necessary.—I am, etc.,

B.L.A. P. FRANKEL,
Capt., R.A.M.C.

Belsen Camp

SIR,—I know it was impossible for Dr. W. R. F. Collis (June 9, p. 814) to include everyone in his excellent article on Belsen, but a tribute should be paid to Lieut. F. J. Murray, to Paul Dupont who offered his services as a stretcher-bearer, and to personnel of "D" Platoon, 567 Company R.A.S.C. (American Field Service). This unit, consisting of volunteers from the U.S.A., carried out magnificent work in helping us to clear the horror camp. Nothing was too big for them, and I have never known men so hungry for work or more willing to co-operate in any task.—I am, etc.,

B.L.A. M. W. GONIN,
Lieut.-Colonel, R.A.M.C.

Bureaucracy and the Control of Medical Appliances

SIR,—For about two years medical supplies reaching this country from America have been on a "Lease-Lend" basis, and subject to the control of the Ministries of Health and of Supply. Many of the profession may not be aware that if they desire to purchase a product from the U.S.A. through one of the various instrument retailers these firms are not at liberty to order and sell such articles as they feel disposed to do, but are under orders from the above Ministries as to purchase and disposal, and, in fact, have become styled "agents for the Ministry of Supply." The muddle and chaos that customarily occur when bureaucracy takes a hand in trying to control and direct the affairs of private enterprise have again become evident in this particular field.

In my own experience the interior of an x-ray tube, known as the insert, was ordered officially in November, 1943, and was delivered to the hospital concerned in May, 1945—only 18 months overdue. In May this year a certain type of x-ray tube insert was requested, but the Ministry appeared to be out of stock of the particular article, and released a substitute with the implication that it could be accepted or left, as there was nothing else to offer. This substitute lasted exactly 30 days, and each new insert costs £55 per tube, although in fairness to the Ministry of Supply it is recorded that full allowance is to be made for the tube that lasted 30 days. The Ministry, of course, have very carefully absolved themselves from all responsibility as to the honesty of the state or manufacture of the product by inserting a clause in their contract form that: "This material is Lease/Lend and there is no guarantee or warranty given." I wonder if our American friends know of this gross injustice regarding their products and their sale conditions in this country. I do know, however, of the indignation of their British "agents." As the result of the above failures a third insert tube was ordered from the Ministry, and, amazing as it may appear, they still had not a supply of the particular article and offered yet another variety and a third type. I could enumerate other medical appliances that have been on order for over 18 months, but to date there is no sign of release by the Ministries concerned.

In 1943 a deputation of representative members of the British Institute of Radiology to the Ministry of Health discussed this matter of defective supplies of x-ray equipment which was then being felt throughout the country. The Ministry gave some assurance that the defect would be remedied, but to-day chaos continues. Further, the B.I.R. asked for representation on the appropriate committee controlling these matters, but the request, made on two separate occasions, was refused. As far back as 18 months ago these tubes and spare parts were being manufactured in America in adequate quantity for the requirements of both U.S.A. and Great Britain, and they only needed collection. The usual plea of shortage of shipping space was put forward by the Ministry, and still apparently is the excuse to-day. I suggested then that these parts occupying very small space could (and can now) reach this country in many of the almost empty aircraft coming here, and at one time landing at the rate of so many per hour daily. Some Americans are amazed at, in fact suspicious of, our lethargy in failing to collect these precious articles.

I need not dwell on the implications these facts have for a full-time salaried health service. We are a very tolerant people in this country, but surely even the Director-General of the E.M.S. cannot tolerate this continued state of inefficiency and mismanagement. How much longer are we to be subjected to unnecessary and humiliating control? The firms concerned are quite competent to resume the individual control of their business and to order the right types and adequate supplies of the goods which they know, much better than the Ministerial mind, are required for the smooth running of the profession in this country. The public must also suffer if the doctors are to be denied the tools with which to carry out the work.—I am, etc.,

London, W.1. NORMAN P. HENDERSON.

The Beveridge Report

SIR,—In this report, which is so universally accepted, there is a grave fallacy which the medical press at least should notice. It contrasts the crude mortality of London in 1900 and 1935—namely, 18.6 and 11.4 respectively—as evidence of progress. Crude rates, especially of single towns and years, have value for generalization in only one respect—they suggest a weak case. It is so here. The standardized rates for England and Wales) were for 1891–1900 and 1901–10 respectively 18.1 and 15.2. Such a rate of fall, continued for twenty years, would of itself have brought us by the end of 1930 to less than London's crude rate of 11.4. But it was gaining speed; the work of last century was beginning to tell in the elder groups, and 45, 55, 65 were all diminishing instead of increasing the national mortality, and for the second half of the decade the rate was only 14.4, falling in 1910 to 13.2. That set a norm henceforward; and for 1911–15 it was only 13.8, though, including two years in which the burden of the Insurance Act was plain, one of them also having its figures based on civilians only—i.e., on a residuum of the less fit. In 1912 it fell to 13.0; had we then enjoyed the same low birth rate and infant mortality as 1935 the low record would have been equalled. In any case in 12 years before the Insurance Act progress was about four times as fast as in the 23 years after, when the State was very active in benefactions. The argument is a poor one for extending the Act, but a powerful one for making it optional.

The great advance of medicine in all branches in this century would naturally suggest speeding-up rather than slowing of progress; and in the case of the well-to-do no one suggests it has been slowed. Nay, all the State solicitude aims at providing for poor people what the rich can provide for themselves. That the provision does not reach the poor is plain; our infant mortality, according to Mr. Titmus, is higher than in any other civilized country *among the poor*; and at no time in this century, said Sir George Newman, has the mortality of youth fallen so rapidly as it did in 1860–90; and in 1911–20, for the first known time, death discriminated against the young.

That, by ensuring a rising standard of real wages and leaving the rest to science and to the people themselves, Government can ensure a rising standard of health was conspicuously shown last century; and by two remarkable control experiments in the two great wars, which, for the first known time, moved poverty from the poor. The commentary of the Registrar-General's annual report for 1919 shows how from 1916 onwards there were established a series of low records of mortality—that is, after the money wages had overtaken the rise in prices; and the course of events in this war has been similar. Sir William Beveridge himself (par. 461) has upset the whole report. He says, "Freedom from want cannot be forced on democracy nor given to democracy; it *must be won by them*." That is true, and he speaks as responsible for the dictum. Could the report have been written with that for text instead of belated confession?—I am, etc.,

London, S.E.26. B. G. M. BASKETT.

Electro-convulsive Therapy Apparatus

SIR,—From a letter in the *Journal* of June 30 (p. 926) I gather that there is some dispute as to the technical performance desirable in electric convulsion therapy apparatus. I should like to pour oil on these troubled waters to some extent by pointing out that the conditions for satisfactory working are not nearly as critical as was at first supposed. From experiments made both in this country and abroad it would appear that the ratio between the average convulsive "dose" and the minimum lethal dose of electric current is at least 1–50, in respect of duration, so that even the simplest switch apparatus would seem quite adequate for both convenience and safety.

The importance of exact measurement of patient-resistance has also been somewhat exaggerated, since this resistance bears little or no relation to the convulsive threshold and actually serves only to satisfy the operator that the patient circuit is continuous and that no leads are frayed or broken.

In electromedical subjects it would seem most important to establish at an early stage of development the limits of accuracy and intricacy which are desirable in any particular type of equipment. In some fields there is a tendency to under- and in some to over-design. Both tendencies are harmful, since the one leads to untrustworthy results and the other to excessive cost and restricted scope.—I am, etc.,

Bristol. W. GREY WALTER.

Alien Doctors

SIR,—In three successive issues of the *Journal* letters have appeared referring to foreign doctors in what can be only described as hostile terms. In that of June 30 (p. 927) Dr. Wm. A. O'Connor went further and reference was made to "what Major Stallard euphemistically refers to as Central Europeans" and "'Central European' doctors and other strange importations." It is difficult to appreciate quite what is meant by these phrases, and one wonders whether the Irish who have remained neutral throughout the war are included. We have just ended a war in Europe against the leading exponents of the race theory, and it is with some misgiving that one reads letters of the type to which I refer.

There are three points which I would like to raise. In the first place every doctor who can practise in this country is serving this country; there can be no doubt about this. Furthermore, the Central Medical War Committee can control almost entirely what work every doctor does. Secondly, it should be possible for you, Sir, to publish how many "foreign" doctors are employed in this country—i.e., those who come under the category of "refugees"—and also how many practise in the coveted area of which Harley Street is the centre. What percentage these doctors represent of the total doctors in that area can also be determined. This information should be obtainable from the Central Medical War Committee. Thirdly, what exactly is the position regarding the return to Europe of these doctors? I understand that our own Government is not prepared at present to allow the return even of those who want to go.

I think it is most irresponsible to raise the question of the position of the refugee doctors unless the facts are fully known, and the writers of the letters referred to could not have possibly known the facts. It is too easy to stir up unjustifiable hostility to foreigners. Besides, this country has always boasted of its granting asylum to refugees, and our profession has liberal traditions of which it is proud.—I am, etc.,

University College, London. J. JOSEPH,
Captain, R.A.M.C.

Education of Nurses

SIR,—I would like to endorse whole-heartedly the views expressed by Mr. A. Wilfrid Adams (June 16, p. 857). In this connexion may I draw attention to the syllabus of the Queen's Institute of District Nursing? Apparently, trainees who are already qualified nurses on the General Part of the Register are to have a six-months smattering in all sorts of subjects, ranging from district nursing and social science (whatever that may be) to blood pressure, including an "explanation of high and low blood pressure" and "method of taking blood pressure." On the other hand, only two lectures "by medical officer of health or specialist" are devoted to infectious diseases. There are to be eight lectures on public health legislation and administration, two on psychology, two on nutrition and dietetics, four on tuberculosis, four on hygiene, and one or two on V.D. The syllabus is a good example of an overloaded and ill-balanced curriculum.

It would seem that the education of nurses has somehow got into the hands of the wrong people, and that the needs of the patient and the medical practitioner are overlooked. Is it not time that the medical profession not only expressed its views but took steps to make them felt?—I am, etc.,

Exeter. G. B. PAGE.

The Services

Col. the Right Hon. Walter E. Elliot, *M.C.*, M.B., F.R.C.P., F.R.S., former Minister of Health, has been appointed Honorary Colonel of the Royal Corps of Signals, Territorial Army, in succession to Lord Stevenson.

Major-Gen. E. Phillips, C.B.E., D.S.O., M.C., late R.A.M.C., has been appointed C.B. (Military Division) in recognition of gallant and distinguished services in North-West Europe.

Fl. Lieut. R. Logan Ewing, R.A.F.V.R., was mentioned in dispatches in the 1945 New Year Honours and was appointed M.B.E. (Military Division) in the recently published Birthday Honours. Squad. Ldr. H. T. Macaulay, R.A.F.V.R., was mentioned in dispatches in the Birthday Honours published last month.

Flight Lieut. (Mrs.) Phyllys P. Pigott, R.A.F.V.R., has been mentioned in dispatches.

Major G. Singh, Jaipur Medical Service, Indian State Forces, has been awarded the D.S.O. in recognition of gallant and distinguished services in Italy.

CASUALTIES IN THE MEDICAL SERVICES

Missing.—Acting Squad. Ldr. Robert William Stanley Marshall, R.A.F.V.R.

DEATHS IN THE SERVICES

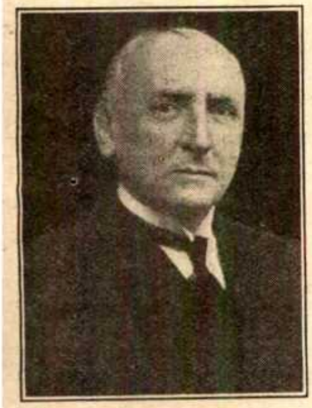
Capt. ST. GEORGE EYRE HARRIS, O.B.E., who served continuously with the R.A.M.C. as a temporary and war substantive officer from 1915 onwards, died at Farnborough on May 27, aged 68. He studied medicine at Trinity College, Dublin, graduating M.B., B.Ch. in 1899 and M.D. in 1902, and was for a time resident medical officer at the National Sanatorium for Consumption, Bournemouth. At the beginning of the last war he was senior surgeon to a French hospital at St. Malo and from 1917 to 1941 was associated with the Cambridge Hospital, Aldershot—as ear, nose, and throat specialist for most of the time. From 1941 he was employed on medical boards. Capt. Harris's long service with the Corps made him widely known to officers of the regular R.A.M.C.

Obituary

THOMAS BEATTIE, D.C.L., M.D., F.R.C.P.

The death, at the age of 77, of Emeritus Professor Thomas Beattie removes an outstanding figure from the medical profession of Newcastle-upon-Tyne. He was a native of the city, his father, Alderman John Beattie, being mayor in 1900. His whole professional career was spent in association with the Royal Victoria Infirmary and the University of Durham College of Medicine in Newcastle.

He qualified in 1890, gaining first-class honours in the final M.B., B.S. examination; in 1895 he was awarded the gold medal for his M.D. thesis. He became a Member of the Royal College of Physicians in 1898 and was elected a Fellow in 1915. Passing through the usual resident posts he became honorary assistant physician, honorary pathologist, honorary physician, and was made consulting physician in 1927 on his retirement from the active staff. In the Medical School he filled various posts—lecturer in materia medica, professor of therapeutics, lecturer in medicine, and finally professor of medicine. In 1935 he received the honorary degree of D.C.L. from the University of Durham.



It may be fairly said that his passing removes the last link with the older school of physicians of Newcastle. His precise and painstaking manner in clinical teaching, together with his outstanding physical attributes and personality, have left a lasting impression on his colleagues and numerous generations of students. He took an active part in local medical affairs, passing through the presidential chair of the Northumberland and Durham Medical Society and also that of the North of England Branch of the British Medical Association. At the Annual Meeting of the B.M.A. in 1921 he presided over the Section of Medicine. During the 1914–18 war he served as lieut.-colonel in the 1st Northern General Hospital in Newcastle. His later years were beset with physical difficulties which he bore with stoicism and without any alteration in his habits or manner. He died in the hospital he had served so long and well. A memorial service was held on June 28 in St. Luke's Chapel in the Royal Victoria Infirmary. It was attended by many old colleagues and members of the House Committee.

Prof. G. **GREY TURNER** writes:

Dr. Thomas Beattie was a well-known physician in Newcastle-upon-Tyne and the North Country, and by his death a notable personality has passed on. Beattie was from first to last a Newcastle product. He was born in that city 77 years ago and obtained his early education at the Grammar School. His medical education was carried out at the University of Durham College of Medicine, which has always been located in Newcastle. During his academic career, which was very successful, he gained many prizes, scholarships, and other distinctions. After obtaining his university degree he held a long series of resident posts at the Royal Infirmary extending over five years, and was also secretary to the medical staff. These years furnished a wonderful opportunity for one with the capacity and avidity to profit by what was happening in a great institution which has always been a storehouse of clinical material. His career at that stage was an apt reminder of William Hunter's remark that "were he to make a man truly great in his profession, he would place him in a great hospital where he might attend the sick and dissect the dead," which is just what Beattie did, using his abundant opportunities to the utmost. Beattie was always a great student of morbid anatomy, and after leaving the house and returning as a member of the staff, his first post in 1895 was as pathologist. In that appointment he carried out his work with great diligence, making all the post-mortem examinations himself. He spent hours in the dead-house conducting each examination with minute thoroughness and inculcating in his clerks those powers of observation which he had so highly developed. In 1897 he became assistant physician, and continued on the medical side until his retirement as senior physician on attaining the age limit in 1927; thereafter he was promoted as consulting physician. Though he filled other offices he never allowed anything to interfere with what he considered the major business of his life—his work at the Infirmary. During the 1914–18 war, with the rank of lieut.-colonel, he did an enormous amount at the 1st Northern General Hospital, including a much larger share of medical board work than fell to the lot of other members of the staff. Everything that he did in his military capacity was carefully recorded, and his reports, written in his own hand, were a model of accuracy and fullness. After retiring from the staff at the Infirmary he became director of the medical division at the Newcastle General Hospital, and there he continued the same high standard of clinical work. At the College of Medicine he held the lectureship in therapeutics until on the retirement of Prof. Oliver from the chair of medicine he was appointed and occupied that position for seven years. His lectures were good and were valuable for those who already possessed a good groundwork, but they were not of the same high standard as his bedside teaching.

Beattie was happiest when working late. He and I often met at a near-by letter-box in the old days just before midnight and there, standing in the open air, Beattie would always be willing to talk for quite a long time about some experiences of the day or to expound something that had bearing on cases of interest or current medical affairs. He never lost interest in surgery, and it was indeed a happy experience to meet him in consultation, to talk over the problems presented, and to have his critical eye on the operative field and in the analysis of the subsequent events. As a young man he had a tuberculous pulmonary lesion which compelled him to stay for a year or more in Switzerland, where he co-operated so thoroughly in his own treatment that a lasting cure resulted. This experience directed his attention to chronic pulmonary diseases, and was reflected in his own management of similar cases. His knowledge of tubercle in all its forms was very wide. He wrote little, but his apparent neglect in that respect was founded on a conviction that there was always so much more to be learnt that it was dangerous to commit to writing what might be improperly digested knowledge, and possibly misleading to younger men. As an examiner he was very fair, and though possibly a little terrifying to the candidate, he appreciated honest effort. As a physician no one could have spent more time and trouble in bedside investigation, which was then and for long afterwards the vogue. Up to the end of his hospital days he was rather suspicious of the ancillary aids, and he tended to lag behind what was becoming current practice in those fields. But his knowledge of disease and its natural history was very extensive, and few men could have had a greater practical experience. It was not that he belittled or scorned additional aids, but he early detected the tendency to allow these methods to replace clinical examination, and to this he would never yield. He applied with great thoroughness those lessons he had so well learned during his early studies in the wards and the dead-house. With Beattie there was never any hurry, and he would take no end of pains to establish a diagnosis. He trained his house-physicians in the same careful and thorough manner, and he expected from them a very high standard of ordinary clinical work. This thoroughness was the great characteristic of all his work. Time and place made no difference, and whether in the convenient atmosphere of the hospital or late at night in the surroundings of some small country home his standard never relaxed. In his management of patients he was sometimes accused of being rather harsh, but it is certain that he never proposed any discipline more rigid than he would have applied in his own case. Thomas Beattie was a most helpful consultant, and many of us are grateful for his assistance in times of difficulty. He was very easy, almost careless, about fees, especially if his interest was aroused in some clinical problem. After his retirement and indeed up to the outbreak of this war Beattie was regular in attendance at meetings of the house committee of the Newcastle Infirmary. Until his health broke down about two years ago he had been actively occupied as president of recruiting boards. Whatever he undertook—and his professional occupations were many—he carried out to the utmost of his capacity and according to his own rigid interpretation of his duty. Throughout life he had to face a succession of personal trials, but these he bore unflinchingly and with great courage, and no one ever heard him complain.

EDWARD BARCLAY-SMITH, M.D.

Emeritus Professor E. Barclay-Smith, for many years one of the pillars of the Anatomical Society of Great Britain and Ireland, died in London on July 5, aged 84. In 1927 he resigned the chair of anatomy in the University of London, tenable at King's College, where he was also for some years Dean of the Medical Faculty; he had been chairman of the Board of Intermediate Medical Studies, and of the Board of Human Anatomy and Morphology in the University, and represented the Council of the College on the committee of management of King's College Hospital.

Edward Barclay-Smith—son of Capt. W. E. Smith, a musketry expert, and Louisa Barclay, daughter of a naval officer—was educated at Brighton College and Downing College, Cambridge. After clinical training at the London Hospital he took the M.A., M.B., B.Ch. degrees in 1890 and proceeded M.D. three years later. Returning to Cambridge he became demonstrator under Prof. Alexander Macalister and won the regard and admiration of a long line of students in the dissecting room; later he held the position of lecturer in advanced human anatomy at Cambridge before his appointment at King's College, London. His gifts as a teacher and organizer were widely recognized. He edited several editions of Buchanan's *Manual of Anatomy* and saw Buchanan's *Dissection Guide* through the press; he was for many years an active member of the editorial committee of the *Journal of Anatomy*; and he examined in human anatomy for the Universities of Cambridge, Durham, London, Manchester, and Birmingham, and for the English Conjoint Board.

Barclay-Smith had been a member of the Anatomical Society for well over 50 years and held office as treasurer 1931–7, and as secretary for the very long period 1919–38; he declined its presidency in order to carry on in the congenial post of secretary. He wrote a short but valuable history of the society and assisted in the preparation of its *Proceedings*. In all his work for the society and for the advancement of its aims he constantly sought to help and encourage younger members. He was also a member of the Association des Anatomistes.

Mr. **John Allison Panton**, F.R.C.S., senior honorary surgeon to the Southport Infirmary, died suddenly on July 1. He had a brilliant career as an undergraduate of the Victoria University of Manchester, winning the Tom Jones exhibition in anatomy, and gold medal, and the senior Robert Platt exhibition in physiology in 1913. On graduating M.B., Ch.B. in 1916 he was awarded distinction in obstetrics and gynaecology and bracketed equal for the John Henry Agnew scholarship in diseases of children. He held a temporary commission in the R.A.M.C. for over three years and then became resident surgical officer at Ancoats Hospital, demonstrator in anatomy in the University, gynaecological house-surgeon and acting resident surgical officer at St. Mary's Hospital, Manchester, and surgical registrar at the Royal Infirmary. In 1921 he received the gold medal for his M.D. thesis and four years later took the Ch.M. degree and the Fellowship of the Royal Colleges of Surgeons of England and Edinburgh. After a short period at Bolton he joined the staff of the Southport Infirmary as honorary anaesthetist and later as honorary surgeon. Mr. Panton was an active member of the Manchester Medical and Surgical Societies, and was for three years honorary secretary of the Southport Division of the B.M.A. He published in the *Journal of Anatomy* a paper on factors bearing upon the aetiology of femoral hernia.

Mr. **David Davies**, consulting ophthalmic surgeon to the Kent and Sussex Hospital, Tunbridge Wells, who died on June 18, aged 72, was a student of University College Hospital, qualifying in 1898 and taking the M.B.Lond. a year later. After serving as house-surgeon and ophthalmic assistant at U.C.H. he became chief clinical assistant at Moorfields Eye Hospital and later set up in practice at Tunbridge Wells. Besides his work at the general hospital he was ophthalmic surgeon to the borough council schools, to the Hermitage Training Home at Uckfield, and consultant to the Crowborough Cottage Hospital and other local institutions. David Davies joined the B.M.A. in 1902 and was honorary secretary of the Tunbridge Wells Division from 1918 to 1934, acting in a joint capacity for the last three years. He was a member of the Ophthalmological Society of the United Kingdom.

Dr. **George Wallace Eustace**, who died in London on June 18, was a former mayor of Arundel, Sussex, author of a history of the borough and castle, and chairman for thirteen years of the county bench. Born at Donnybrook, Co. Dublin, on April 25, 1870, son of Marcus Eustace, F.R.C.P.I., he was educated at Corrig School, Kingstown, and Trinity College, Dublin, where he graduated B.A. in 1891, M.B., B.Ch., B.A.O. in 1893, and M.A., M.D. in 1898, after winning a senior moderatorship and gold medal in natural science and first-class honours. From 1894 to 1921 his practice was at Arundel. He saw active service in the South African War, and in France and Flanders with the Sussex Yeomanry during the last war as captain, R.A.M.C., and was awarded the Military Cross. In 1921 Dr. Eustace became regional medical officer under the Ministry of Health, retiring in 1927. He had been on the staff of the Arundel Cottage Hospital and honorary radiologist to the Royal West Sussex Hospital, Chichester. He joined the B.M.A. in 1894, and held office as chairman of the Chichester and Worthing Division twenty years later. He was devoted to fishing and field archaeology and published a number of articles on the antiquities of West Sussex. During the present war he had been medical officer to the R.A.F. and W.A.A.F. camp two miles from his home.

Dr. **Edgar James Tyrrell**, who practised in the City of London for many years and undertook much work for insurance companies, died on June 16, aged 66. He was educated at the University of Durham College of Medicine, Newcastle, graduating M.B., B.S. in 1915, and afterwards took the Cambridge D.P.H. and the D.M.R.E. In the Durham examinations he won honours and university prizes. He had served as a private in the R.A.M.C. during the South African War and held a commission as captain in 1915–17; for four years after the armistice he was medical referee under the Ministry of Pensions for the borough of Fulham. Dr. Tyrrell had been clinical assistant in the electrotherapeutic and *x*-ray department of the West London Hospital and at the Lock Hospital, and took a special interest in skin diseases, winning the Chesterfield medal in dermatology at St. John's Hospital in 1924. A correspondent writes: The death of Dr. Edgar J. Tyrrell deprived the City of London of a well-known character. Affectionately known as "The Stock Exchange Doctor," he had practised at 33, Cornhill since 1918, chiefly among the insurance offices and other companies, many of whom regarded him not only as a valued adviser but as a beloved friend. He left his Devonshire home as a youth to serve as a dresser during the Boer War, and afterwards spent some time in various ventures in South Africa. Returning to England he took his degrees at Durham University, and served as an R.A.M.C. officer in the last war but was invalided from the Army after the Somme battle of 1916, with a heart so much impaired that he was told by a distinguished consultant to "run away and play, for he had only six months to live." A born fighter, he determined to cheat the prophecy, and from then until six months before his death he devoted himself to his city practice, although handicapped by increasing ill health. The declaration of war in 1939 found him over age for Government service in any form, but he resolved to stand by the companies whose interests were so near his heart, and even when a bomb fell just outside his offices he continued his visits to the city under utmost difficulties, and at the cost of a severe strain on his enfeebled health. Only most urgent symptoms at last induced him to seek medical advice. A severe operation was followed by six months of extreme suffering, which he bore with a calm fortitude inspired, as was his whole life, by a humble and sincere religious faith.

Dr. **Martyn Cecil Beatty**, who practised at Broadway, Worcestershire, for the past fifteen years, has died in Evesham Hospital at the age of 70. After graduating M.B., Ch.B.Ed. and taking the D.P.H. he served in the R.A.M.C. for thirty years, reaching the rank of lieut.-colonel. He saw active service in the South African War, and after being stationed in Northern Ireland, in India, and at Plymouth, went to France with the first Expeditionary Force, and later to Egypt and the North-West Frontier, and joined the Army of Occupation at Cologne and Wiesbaden. During this war he lectured and helped to train members of the first-aid post at Broadway and was on the panel of doctors examining recruits at Worcester.

Dr. G. H. Pringle, M.O.H. for Bridgwater, writes: It was my privilege to work with Dr. H. J. **Phillips** as his deputy in Worthing from early in 1939 until the summer of 1941. His administrative ability and flair for organization were outstanding assets, though his talent was by no means limited to this sphere. As a clinician he was at his best at the borough isolation hospital. The outbreak of war brought with it the heavy burden of evacuation, and to add to the difficulties the trend of events meant that Worthing, in a short period, not only ceased to be a reception area but an official evacuation took place. This sudden change from apparent safety to the danger of a front-line town put a heavy strain on the C.D. organization's casualty services, which had to be rapidly augmented. Thanks to Dr. Phillips all these difficulties were successfully overcome. As can be expected from a hard worker, Dr. Phillips had no time for slackers, though he always showed the greatest consideration to all members of his staff. In his scanty leisure hours I have happy recollections of an occasional game of tennis in his lovely garden, and, even in the dark days of the autumn of 1940, lively discussions on our common hobby of philately. I look back on my time in Worthing as an education in sound and tactful administration. By the sudden passing of Dr. Phillips I have lost a good friend, and a progressive borough has lost a progressive medical officer of health.

Universities and Colleges

UNIVERSITY OF BIRMINGHAM

At a Congregation, held on June 30, the following medical degrees were conferred:

M.B., Ch.B.—*J. R. G. Bastable, *J. L. Stafford, †L. D. Abrams, A. F. Alvarez, H. J. Bagnall, Clarice E. Butler, J. M. Crossley, Muriel J. Davies, Helena M. Ellis, R. H. Freeman, Doreen E. George, R. L. Greenwood, Zoe Hartley, P. Hogg, G. B. Hopkins, G. Hoyle, ‡J. G. Jackson, A. T. Johnson, Barbara D. King, J. D. Lacon, R. S. Male, Joan Marsden, Martha H. Martin, ‡Doreen M. Matthews, Hilda M. Morgan, D. E. Oakley, J. S. Owen, M. W. Parker, ‡A. J. Pearce, M. J. Peto, J. G. Piccaver, D. J. Rigby, M. J. Roper-Hall, R. H. Sage, W. H. Scrase, M. H. Stroud, A. E. Szulman, N. A. Thomas, R. R. Trussell, Helen M. H. Wilson, Joyce E. Wiseberg, Joan S. Woodhouse, D. Zuck.

* Second-class honours. † Distinction in surgery. ‡ Distinction in medicine.

The following scholarships, etc., were awarded in the Faculty of Medicine:

Queen's Scholarship (Third Year): F. B. Buckley, Jean M. Smout. *Queen's Scholarship (Fifth Year):* Barbara M. Ansell. *Ingleby Scholarships:* C. A. Jewels, W. J. Walkden. *Arthur Foxwell Memorial Medal* and *Priestley Smith Prize in Ophthalmology:* J. N. Ormrod. *Sampson Gamgee Memorial Medal:* W. J. Walkden. *Queen's Scholarship (Final Year):* C. A. Jewels. *Leith Newman Prizes in Pathology (Fourth Year):* Margaret L. Fallon, Rose A. J. Whitelaw. *Peter Thompson Prize in Anatomy (Third Year):* Jean M. Smout. *Russell Memorial Prize:* J. L. Stafford. *Bertram Windle Prize in Anatomy:* B. D. Bower, E. W. Clarke. *John Barritt Nelson Memorial Gold Medal:* F. B. Buckley. *Foyle Prize:* N. K. Shinton. *Alexander Youngson Prize:* H. E. Schweinburg. *Lawrence Barnard Carlton Scholarship:* P. A. Bramley. *John Humphrey Memorial Prize:* J. A. C. Smith.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—I. Ansell, H. Dakin, B. Phillips, G. O. Thomas, P. H. Whitaker.

Ch.M.—L. McK. Crooks.

Final M.B., Ch.B.—*Part III:* Beryl G. Anscombe, G. Ansell, K. W. Baruch, B. Dover, Monica Drinkel, J. W. L. Edwards, P. Foster, B. R. Frisby, S. Gillis, L. Griffiths, B. B. Harrison, D. C. R. Jones, J. T. W. Jones, P. R. B. Jones, R. V. Kinnish, M. Kirwan, Joyce R. Lewis, J. B. Roberts, Corris Venables, H. Wickham, J. R. E. Wilson. *Passed in Separate Subjects:* A. D. Charnley and M. M. I. el Haddad (Medicine and Surgery). R. Ellam (Surgery and Obstetrics and Gynaecology). *Final Examination: Part II.—Passed in Forensic Medicine and Toxicology.*—Joan Evans, P. Hampson, Vivien P. Helme, Maureen M. Hoey, D. T. L. Hughes, Nellie Hughes, J. C. Rumber, L. Robinson, L. Rosenbloom.

UNIVERSITY OF ST. ANDREWS

The following candidates have been approved at the examination indicated:

M.B., Ch.B.—*Diana Butler, †R. T. D. Emond, †D. A. Grewar, †K. R. Keay. †W. D. Mackenzie, †Nancy M. E. Robertshaw, †T. Sanderson, †A. T. Sandison, †D. P. A. L. Scott, I. M. Baird, W. Bryson, W. H. Condie, Agnes K. Conn, Vivienne A. Croxford, Jean B. Davidson, Janet M. Donald, Christina C. Ferguson, D. M. Ferguson, J. G. Ferguson, A. P. M. Forrest, W. Frain-Bell, A. R. G. Gordon, Jean G. Gordon, J. S. Innes, N. G. Johnston, R. I. Just, W. F. Kinnear. J. L. McDougall, W. S. Macmillan, Margaret Mann, Louise I. S. Millar, J. G. Millers, A. A. Mudie, I. S. Mudie, N. Murray, Margaret H. Mutch, E. G. Naylor, W. D. Paterson, Ruth Sabel, Mary J. M. Shaw, R. D. Simpson, T. V. Simpson, R. R. Stevenson, D. C. H. Tullis, H. R. Turner, Mary E. Walker, I. C. Whyte. H. Williams.

* With distinction. † With commendation.

UNIVERSITY OF DUBLIN

At a Congregation, held on July 4, the following medical degrees were conferred on students of the School of Physic, Trinity College:

M.D.—R. T. Burkitt, H. L. Parker.

M.B., B.Ch., B.A.O.—Etheline E. Hopkins-Brady, Margaret E. Brook, Elizabeth P. Carlisle, W. J. H. Collins, G. F. Corbett, P. F. Daly, Gwendoline E. Davison, D. A. N. Drury, R. F. Fouché, R. Graham, D. McK. Hamilton, J. W. Jackson, J. D. Llewellyn-Jones, F. T. Kee, G. L. Kennedy, Jean H. King, J. G. Kirker, R. L. McClelland, T. C. Millar, Mary A. Montgomery, J. H. Murphy, J. B. Musgrave, R. Smith, Barbara M. Stokes, S. D. Walsh, Anna M. Grove-White, S. W. Wolfe.

QUEEN'S UNIVERSITY, BELFAST

The following candidates have been approved for medical and surgical degrees:

M.D.—J. W. Beattie, J. T. Carson, H. S. Hogg, H. E. Rutherford, S. Ruttle, *By Thesis:* S. J. Allen (with high commendation), Elizabeth F. McKeown (with gold medal), Yvonne A. Murray (with gold medal).

M.Ch.—J. P. McGinley.

M.B., B.Ch., B.A.O.—D. A. Bain, D. M. Bell, G. Dornan, Laurna Evans, H. F. Fleming, R. Fulton, E. M. Hamilton, Eileen E. M. Hanna, J. T. Heron, A. C. Houston, M. H. A. Jamison, R. V. C. Kerr, R. F. Keys, Joan B. M. Leith, T. G. Lowry, J. J. McSorley, J. D. H. Mahony, W. M. Martin, J. J. O'Brien, C. F. Patterson, Kathleen Powell, J. H. Stewart, Laura Thompson, S. Thompson, R. P. Thornton, J. F. Walsh, D. H. Warden, A. Warnock J. E. Watson. *With Second-class Honours:* J. D. F. Leith, J. R. Milliken, S. R. C. Ritchie.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Election to the Council

On July 5 four Fellows were elected into the Council to fill the vacancies caused by the retirement in rotation of Surg. Rear-Adml. C. P. G. Wakeley, Mr. L. E. C. Norbury, and Surg. Capt. L. C. Rogers, and by the death of Mr. C. A. Joll. The Fellows elected were:

	Votes
Cecil Pembrey Grey Wakeley (King's College) ..	840
Lambert Charles Rogers (Cardiff)	835
Lionel Edward Close Norbury (Royal Free) ..	716
Robert John McNeill Love (Royal Northern) ..	546

The following were the other candidates:

Arthur Dickson Wright (St. Mary's)	483
Arthur Lawrence Abel (Princess Beatrice)	417
Henry Hamilton Bailey (Royal Northern)	349

In all 1,322 Fellows voted; in addition 20 votes were found to be invalid. Surg. Rear-Adml. Wakeley, Mr. Norbury, and Surg. Capt. Rogers are all elected for the full period of eight years. Mr. McNeill Love is elected as a substitute member for two years.

Medical News

A meeting of the Association of Clinical Pathologists will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday and Saturday, July 20 and 21, at 9.30 a.m.

A clinical meeting of the London Association of the Medical Women's Federation, arranged by members of the staff of University College Hospital, will be held at the Maternity Hospital, Huntley Street, W.C., on Saturday, July 21, at 3 p.m.

By courtesy of the Royal Society of Medicine, the British Association of Physical Medicine has arranged to show a sound film on the management of infantile paralysis by the Kenny method. This film, which claims to adduce evidence in support of the rationale underlying the originator's unorthodox concept of the disease, will be shown in the Barnes Hall, at 1, Wimpole Street, W., on Monday, July 30, at 2.30 p.m. A discussion will follow an interval for tea. The President and members of the B.A.P.M. extend a cordial invitation to Fellows of the R.S.M. interested in this subject.

Prof. A. Baudouin, who visited England recently with other leading French physicians and surgeons, has been re-elected dean of the Paris Faculty of Medicine.

Prof. Roussy, member of the Institute and rector of the University of Paris at the beginning of the war, has been elected general secretary of the Académie de Médecine in succession to the late Prof. Achard.

Boots Pure Drug Company Ltd., of Nottingham, have recently presented the diabetic department of King's College Hospital, London, with funds to provide research scholarships in diabetes and allied diseases. The amount of this gift is £1,000 a year for seven years.

Dr. Smith Ely Jelliffe has resigned the post of editor of the *Journal of Nervous and Mental Diseases,* which he has held for forty years, and is being succeeded by Dr. Dolan D. C. Lewis, of the College of Physicians and Surgeons, Columbia University.

Licences are still required in respect of the export to the Channel Islands of drugs to which the Dangerous Drugs Acts apply. The licences will, as in the past, be issued by the Drugs Branch, Home Office.

The May-June issue of *Industrial Welfare and Personnel Management,* the journal of the Industrial Welfare Society, includes a two-years record of a group medical scheme for industrial welfare by C. F. Richards, a note on penicillin in industrial medicine by Dr. H. B. May, and an account of the first year's work of the Roffey Park Rehabilitation Centre by Dr. T. M. Ling, medical superintendent.

The decoration of officer of the Order of Polonia Restituta has been conferred on Mr. A. H. McIndoe, C.B.E., M.S., F.R.C.S., by the President of the Polish Republic in recognition of services during the war.

The Commonwealth Government of Australia has given £5,000 to the Queen Victoria Cottage Hospital at East Grinstead, Sussex, in recognition of its work for Australian airmen suffering from burns requiring plastic surgery.

The late Dr. Herbert Thomlinson Nixon, of Liverpool, who left estate valued at £53,105, bequeathed, subject to two life interests, £1,000 each to the Royal Medical Benevolent Fund and Epsom College.

A conference of medical consultants, India Command, and medical specialists, Central Command and North-Western Army, India, was held at King Edward Medical College, Lahore, in February, 1944. A large number of officers were present and took part in the discussions on various short papers presented—for example, on malaria, tuberculosis, enteric fevers, tropical eosinophilia, dysentery, typhoid, anaemia, and malnutrition. A 150-page report of the proceedings of the conference has now been published and is available in the library of the B.M.A.

The late Dr. James Richard Whitwell, for many years honorary librarian of the Royal Medico-Psychological Association, who died on Jan. 9, 1945, left £26,318. Subject to a life interest he bequeathed the residue of his estate to form a Whitwell Fund for the benefit of mental patients of St. Audry's Hospital, Melton, or of the Mental After-Care Association, or otherwise for the benefit of "that class of patient to whose welfare I have devoted such a large portion of my life."

The Central Midwives Board has announced an alteration in its rules of training whereby, from a date to be announced later, registered sick children's nurses will be admitted to the shortened period of training extending over six calendar months for the first certificate of the Board.

The Order of the Nile (Fourth Class) has been conferred by the King of Egypt upon Dr. A. R. McKelvie, ophthalmic surgeon, and Dr. N. L. Corkill, chief inspector, Sudan Medical Service, in recognition of valuable services rendered by them.

Alfred Charles Fisher, M.D., has been nominated an unofficial member of the Legislative Council of Northern Rhodesia.

Mr. James C. Young has been elected President of the Pharmaceutical Society of Great Britain.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week there were fewer notifications of infectious diseases, the totals falling by the following amounts: measles 1,264, dysentery 177, scarlet fever 77.

Scarlet fever notifications dropped by 34 in Lancashire. The incidence of diphtheria fell by 17 in Essex, but rose by 16 in Gloucester. Notifications of whooping-cough rose by 27 in Lancashire, and by 22 in London, but fell by 34 in Yorks West Riding. There was a general fall in the notifications of measles, the only important exception being a rise of 30 in Suffolk, where the total was the largest during the current epidemic.

Dysentery notifications, 287, were the lowest since the first week of the year. The only fresh outbreak reported during the week was in Nottinghamshire, Nottingham C.B. 15. The other principal centres of infection were Lancashire 51, London 49, Northumberland 19, Warwickshire 18, Essex 14, Yorks West Riding 14, Derbyshire 11, Kent 10, Oxfordshire 10.

Scotland recorded an increase of 54 and 20 in the notifications of measles and dysentery respectively, but the incidence of diphtheria fell by 14. In Edinburgh numbers of cases of dysentery rose from 11 to 23, and in Glasgow from 25 to 34. It is feared that Glasgow may have a recurrence during the summer of gastro-enteritis, which last August and September caused 269 infant deaths. The cause of this outbreak was never determined, but milk was suspected, as only 22 of the 522 infants admitted to hospital were breast-fed. Steps to forestall an outbreak are being taken by the medical officer of health.

In *Eire* notifications of measles fell by 31, and those of whooping-cough by 21; there was a slight rise of 7 in diphtheria.

Quarterly Returns for Eire

The birth rate during the first quarter of this year was 21.5, which is 1.2 below the rate for the March quarter of 1944. The infant mortality was 89 per 1,000 registered births, being 12 below the rate for the corresponding quarter of 1944, but between 5 and 11 above the rates for 1940–2. The general death rate was 18.4 per 1,000, which is 1.7 below the rate for the preceding March quarter: 718 deaths were attributed to pulmonary tuberculosis, and 250 to other forms, the former being 160 below the average of the five preceding first quarters, and the latter 26 above.

Week Ending June 30

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,255, whooping-cough 1,194, diphtheria 421, measles 6,004, acute pneumonia 424, cerebrospinal fever 52, dysentery 292, paratyphoid 7, typhoid 5, typhus 1.

No. 25

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 23.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week).

---

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

ANY QUESTIONS?

Pregnancy and "White-leg"

Q.—*Would you advise a healthy woman, aged 30, who had white-leg after a breech birth 2 years ago to have any more children? If so, what is the likelihood of a recurrent phlebitis during and after the pregnancy?*

A.—Another pregnancy should not be discouraged. There is no increased risk of a deep thrombosis in either leg after another confinement, and most women who have had white-leg bear subsequent children without any great disability. If the deep venous circulation is permanently impaired the leg is likely to swell to some extent during another pregnancy and the superficial veins may dilate. This could be controlled by an elastic supporting stocking and by adequate rest. The risk of puerperal thrombophlebitis in any superficial varicose veins which might develop could be minimized by encouraging active exercises immediately after delivery and possibly by limiting the lying-in period to 4 or 5 days.

"Flat Feet" in Infants

Q.—*At what age does the arch of the foot become apparent? Does a child of 1 year 9 months who is inclined to throw the weight on the inner side of the foot, when barefoot, need corrected shoes? She wears heels of the "start rite" type with a wedge prolonged under the instep. With these the tendency to throw the weight on the inner side of the foot is not noticeable. She is tall and heavy beyond her age, though not fat.*

A.—The popular view is that all babies have flat feet. On the contrary, at birth the long arch is present, but in the first year or so of life is usually disguised by the plantar fat pad, which in some infants is so prominent as to cause undue maternal anxiety. A child, as described, who really does tend to throw an abnormal amount of weight on the inner side of the foot is probably suffering from a mild congenital talipes valgus. For such a case the Thomas heel, in which, on the inner side, there is a forward extension of half an inch and a 1/16-inch wedge, is advisable. Frequently medical men wedge the inner side of the sole also: this we believe to be bad, for the development of a normal gait does depend upon firm implantation of the first metatarsal head upon the ground. As with all children with mild postural deformities, the aim should be to remove artificial aids as soon as possible. It is, therefore, important to educate the child into good habits of control by games and suitable remedial exercises to improve control in all the muscles of the foot—not, as is so often done, just in the invertors and plantar flexors.

T.A.B. Treatment of Arthritis

Q.—*A nurse aged 50 has developed a multiple arthritis which threatens to cripple her. Would T.A.B. injections be of any use? If so, what doses are recommended, how many, and at what intervals should the doses be given? Is there any danger of adverse effects from the injections?*

A.—Foreign-protein therapy, of which T.A.B. vaccine is an example, may produce temporary improvement in rheumatoid arthritis, but rarely permanent benefit. It is most likely to prove helpful when recovery has begun but seems to be at a standstill. The object is to produce a febrile reaction, and in individuals who have been previously immunized with typhoid vaccine this may be difficult or impossible to effect. Since the shock produced is the object in view it is obvious that the method is to be avoided in the presence of any debilitating condition which might render the patient unfit to bear the further strain, and therefore any circulatory weakness, cardiac disease, hypertension, or acute illness are contra-indications. The usual dosage is to begin with 10 to 25 millions intravenously, repeated every four or five days provided that the temperature has been normal for 24 hours; if the reaction has been severe the same dose should be used, but otherwise it should be increased up to double the first dose. The injections should be continued at the same intervals with a proportionate increase, but if no benefit is experienced should not go beyond four, and in any case not more than five or six should be given and only if the patient is not too exhausted by the reactions. It is well to keep the patient in bed until the temperature is normal after each injection, and also for a few hours before injection. Fluids should be given freely, and the usual methods of treating shock must be adopted if this is severe. There is usually an increase in the symptoms at first, followed by improvement. The adverse effects are those which may arise from shock in enfeebled individuals.

"Struck off the Register"

Q.—*Why does the General Medical Council try cases which have already been tried by the civil courts? If a doctor has been struck off the Register, can he reapply for admission? What happens to his practice when he is struck off? How long must he wait before being re-registered?*

A.—The General Medical Council is not a court of law but a statutory body appointed to keep the *Medical Register* and to see that all practitioners registered in it shall be fit and proper persons to practise. When they call a practitioner's conduct in question, they are concerned merely with inquiring whether he is fit or not to remain on the *Register*. Therefore the findings of a civil court do not bind them, for the civil court has been inquiring into a different issue, often with different parties to it. The Council until recently made an exception in cases where a practitioner was reported to it by the authorities of the Divorce Division as having been respondent or co-respondent to a divorce petition in circumstances which suggested that he had committed adultery with a patient. In such cases the Council's practice was to take the evidence and findings of the Divorce Court as binding on them and to refuse to allow the practitioner to bring evidence in contradiction. The Court of Appeal held in *Ex parte* Spackman (1943) 2 All E.R. 337 that this practice was wrong, and that the Council must hear evidence which either party desires to give as well as the transcript of the Divorce Court proceedings.

The position is different where a practitioner has been convicted before a criminal court of an offence, for in that event the Council has power by section 29 of the Medical Act, 1858, to erase the practitioner's name merely on proof of the conviction.

A doctor is entitled to apply for readmission at any time after his name has been erased, and in dealing with the request the Council will consider whether he is likely to have profited by the penalty of erasure to such an extent as to be fit for readmission. Applications for readmission come before the Council at its November session. The applicant must state the ground on which he is applying, and support the application with a statutory declaration and at least two certificates of his identity and good character signed by fellow practitioners or by a practitioner and a magistrate. The licensing body which gave the practitioner his qualifications originally, and the complainant, if any, may object in writing. The Executive Committee deals with the application and reports to the Council, which considers the report in private and announces its decision in public.

When a doctor's name is erased from the *Register* he is not prohibited from continuing to practise, but he must not hold himself out as registered, he may not use dangerous drugs or scheduled poisons, or do National Health Insurance work, or sign official certificates, or hold any public appointment. His activities are, therefore, severely restricted. Doubtless if he can find a friend to look after his practice he will do so. His former partners may elect to continue it, but as his erasure dissolved the partnership they are under no legal obligation to readmit him if his name is restored, nor can he claim any further interest in the partnership. He cannot continue to practise in association with a registered friend or partner, for his colleague would then be covering him and himself liable to penal erasure. Probably in many such cases an erased practitioner's practice disappears or becomes merged in those of his neighbours.

Haematoma after Hydrocele Operation

Q.—*How can post-operative haematoma in excision of a hydrocele be avoided?*

A.—It is likely that most surgeons have at some time in their early career been annoyed by the formation of a haematoma in the scrotum after they have performed the operation of the excision of the parietal layer of a hydrocele. There is hardly any operation in which it is so necessary to ensure accurate haemostasis, for the lax scrotal tissues exert no pressure on any bleeding vessel and easily allow blood to accumulate.

By due care it is always possible to avoid a haematoma. The blood vessels are close to the outer fibrous layer of the sac, and sometimes it may be possible to peel out the inner thin and avascular lining membrane and avoid cutting away the thicker and vascular outer layer. This will prevent any danger of bleeding. Commonly, however, the fibrous layer must be removed, and then bleeding should be controlled by over-sewing the cut edge of the sac by a catgut suture. This is best done by stages. Section after section of the sac is cut and immediately over-sewn until the whole parietal layer is removed. One or more continuous sutures are used. The sac should not be cut too close to the testicle. Before closing the wound the greatest care should be taken to inspect the whole exposed area and to ligate or underpin even the smallest bleeding point. If this be done there will be no need to drain the wound. After operation the scrotum should be slightly elevated on a small pillow.

There is nearly always slight swelling of the testicle after the operation; this is probably due to the slight trauma caused by handling the organ. An inexperienced house-surgeon has been known to mistake this testicular swelling for a haematoma.

Ectopia Lentis

Q.—*A woman aged 34 was born with ectopia lentis; the lenses became dislocated and had to be removed, following secondary glaucoma. Her daughter, now aged 11, is suffering from ectopia lentis, the vision of the right eye being 1/60, with −20.0 D. Sphere 2/18. The left vision is 6/18 when corrected. What operation would you advise for the right eye in view of the mother's lenses having been dislocated?*

A.—Before attempting operation certain points must be considered: (*a*) Are there any myopic fundus changes and what degree of vision could be expected if operation were successful? (*b*) What is the possibility of detachment of the retina following extraction? (*c*) Having in view the fair vision in the other eye, and knowing the extreme difficulties of any operation, should the worse eye be touched? If the lens can be coaxed into the anterior chamber, the operation is somewhat simplified; otherwise the extraction is very difficult, since the lens tends to run away from any instrument touching it and is usually accompanied with loss of vitreous.

Gastric Ulcer and Femoral Thrombosis

Q.—*Four years ago a patient developed a thrombophlebitis of the left leg, and subsequently a typical gastric ulcer. I now have notes of seven somewhat similar cases in four years. One is tempted to theorize and suppose that products of thrombolysis might possibly act as toxins and cause an ulcer of the duodenum. Is this a known fact, and if so, can the condition result from a "white-leg" of puerperal origin? (My cases were all in women of menopausal age or older.)*

A.—Gastro-duodenal ulceration is present in approximately 2.5% of adults and therefore must frequently coexist with other diseases. No statistical evidence for a special association of femoral thrombosis and peptic ulcer has been seen, and one's impression is that peptic ulcer is uncommon following "white-leg" in the puerperium. Nevertheless, the two factors which favour thrombophlebitis—sepsis and increased coagulability of the blood—also favour the formation of ulcers. The association of sepsis and acute gastric ulcer is well known. Chronic peptic ulcer has been proved to be unduly common in polycythaemia vera, in which there is a tendency to thrombosis. The ulcers are presumably due to thrombosis in the vessels supplying the gastro-duodenal mucosa, and there seems no need to postulate a gastrotoxic action of the products of autolysis of the thrombus in the leg.

Ante-partum Haemorrhage

Q.—*A second-para aged 20, seven months pregnant, called me for severe haemorrhage. On P.V. examination there was a two-finger dilatation, and a tense bag of membranes could be felt. I punctured the membranes to reduce the haemorrhage and quicken the process of labour; instead of the amniotic fluid about a pint of blood and clots came out in a gush. After the condition of the patient was restored, I examined her again. The bleeding had stopped. The uterus was contracting well and the head was fixed. In another six hours the entire foetus was expelled intact in the amniotic sac complete with the placenta. Obviously the bleeding was inside the two membranes, though a part of the placenta was also separated beforehand and a biggish clot was delivered with the foetus. What is the explanation of the condition?*

A.—It is doubtful whether the evidence presented is sufficient to justify the conclusion that the haemorrhage occurred between the chorion and the amnion. Unless liquor escapes it can be difficult to be certain that one or both membranes have been ruptured, and it is just possible that the manipulations in this case released a clot with some dammed-up fluid blood from the chorio-decidual space. If the blood was lying between the chorion and amnion, then, after the products of conception were delivered, the area of separation of the two membranes should have been obvious and there should also have been some remaining blood-clot to confirm the site of the haemorrhage.

If it be assumed that the blood was lying between the chorion and the amnion, then it must have been of maternal origin, if only because the amount was greater than the total volume of foetal blood (in foetus, cord, and placenta) at term. In cases of concealed accidental haemorrhage the blood can burst through the membranes and enter the amniotic sac, and reference to this is found in most of the larger obstetrical textbooks. In certain circumstances, such as an area of weakening or degeneration in the chorion, associated with a tough amnion, it is conceivable that it might break through the chorion only, and then track down between the two membranes. If such was the case here, the tear in the chorion should have been seen after delivery.

Haemorrhage between the chorion and amnion can also occur without any retroplacental haemorrhage, and a case was recently described by W. H. Carlisle (*J. Obstet. Gynaec. Brit. Emp.*, 1944, **51**, 541). In that case the position was proved by demonstrating blood-clot remaining between the membranes after delivery, and it was suggested, although not proved, that the source of the bleeding was the marginal sinus of the placenta.

Suture Materials and their Sterilization

Q.—*What are the various suture materials made of? I should particularly like to know about silkworm gut, salmon gut, silk, and catgut. Can you explain the peculiar nomenclature? Can you let me have a few references to methods of sterilizing suture material?*

A.—Suture materials are of three principal kinds: thread (silk, linen, or nylon), catgut, and silkworm gut. Catgut is spun from strips of the submucosa of sheep's intestine: the origin of its name is obscure. To obtain silkworm gut, silkworm larvae are immersed in acetic acid, the two silk glands are then removed, and the viscous fluid which they contain is drawn out into threads of different length and thickness which are dried in the sun. This type of gut is used largely for casting-lines in rod-fishing; it is often known even in surgical circles as fishing gut, and salmon gut is the stronger variety required for big fish.

Instructions for sterilizing suture materials will be found in most textbooks of surgery. The only serious difficulty arises in connexion with catgut, which is very liable, owing to its origin, to contain the resistant spores of such organisms as *Cl. tetani*, but is softened and spoiled by autoclaving. It can be sterilized by heat and other means during the process of manufacture, and if bought as "sterile surgical catgut" requires no further sterilization. If bought "raw" it can be sterilized only by immersion for ten days in Claudius's solution (iodine 1 g., pot. iod. 1.5 g., water 100 c.cm.). The sterilization of catgut, and the utter inefficacy of other chemical methods of disinfecting it on which reliance has been placed with disastrous consequences even in the recent past, are fully dealt with in the monograph entitled *The Preparation of Catgut for Surgical Use*, by W. Bulloch, L. H. Lampitt, and J. H. Bushill (M.R.C. Spec. Rep. Ser. No. 138, London, 1929). All other suture materials are usually boiled.

Children and Dried Milk

Q.—*There are a number of different makes of dried milk on the market, and the published compositions of a given type (full cream, half cream, etc.) are almost the same in terms of fat, protein, and carbohydrate. Yet it is sometimes stated that a child may not be suited to one make and yet thrive on another. Can individual susceptibility to a particular brand exist? If so, wherein does the difference lie?*

A.—Foods of approximately the same composition can only have the same effect as regards digestibility and gain in weight provided they are given in the same strength or dilution. Magical effects have often been attributed to dried milk "X," for example, as compared with National Dried Milk, even in that particular part of the country where it is known that they are identical. It follows that the good effects attributed to a special brand can only be due to (*a*) the fact that it has been given in a different dilution, or with additions; or (*b*) that the child got well while on this particular brand. This is the most likely explanation in most cases, for so many of the disorders of infancy produce gastro-intestinal symptoms and signs. It is the baby that is wrong in so many cases, not the type of feed, and a change of food is seldom the right move. This must be particularly stressed when the baby is breast-fed; for then a change of cow's milk for symptoms such as vomiting may be equivalent to signing a death warrant.

Spraying Enclosed Spaces

Q.—*Is paraffin or kerosene the best solvent for the spraying of enclosed spaces, such as mess-decks?*

A.—Kerosene (paraffin) is about the most satisfactory carrier liquid for insecticides available at present, since it combines effectiveness, cheapness, and availability with low toxicity to man. It must be realized that there is some fire risk, depending on the flash point of the grade used, and therefore all naked flames must be extinguished and smoking prohibited while spraying is in progress. The most desirable type for many insecticides is "odourless distillate," a grade purified by removal of aromatics (which cause the smell of ordinary paraffin) and of a comparatively high flash point. The only disadvantage of odourless distillate is that it is a rather poor solvent for D.D.T. and will take up only about 3 to 4% compared with the 5 to 8% dissolved by crude kerosene. Some of the unpleasant features of spraying in confined quarters can be mitigated by using a coarser spray. The fog produced by very fine atomizers is required only where it is essential to kill *flying* insects rather quickly.

Intravenous Adrenaline

Q.—*In the* JOURNAL *of Feb. 10, 1945 (p. 208), it is stated that "intravenous injection of adrenaline is a dangerous procedure." In the* JOURNAL *of April 21 (pp. 567, 568), Lieut.-Col. D. C. Macdonald, referring to Prof. Ascoli's treatment for malaria by intravenous adrenaline, states that "it is harmless to the host." It is unlikely that both of these statements can be correct. I should welcome further information.*

A.—Prof. Ascoli's treatment of malaria by intravenous injection of adrenaline has been carried out by this time in a large number of subjects and has at least sufficed to demonstrate that intravenous adrenaline is nearly always harmless, though it is very alarming to the subject. It is safe to say that in patients whose heart and vessels are not affected by pathological changes adrenaline is quite harmless, because it is so rapidly destroyed. In those in whom pathological changes have occurred the sudden great rise of blood pressure which adrenaline produces when put into a vein must expose them to the risk of haemorrhage. The view commonly held that adrenaline injections are always dangerous arises from the effects produced by adrenaline in conjunction with other substances, of which chloroform is the outstanding example. A recent investigation of Ascoli's method of treating malaria, which has not been published, indicates that when a carefully controlled series of observations is made patients suffering from malaria obtain no benefit from a course of intravenous injections with adrenaline.

Hay-fever

Q.—*What is the best treatment for a case of hay-fever now that attacks are at their worst? Adrenaline and ephedrine are being used, though they afford little relief. Is it true that desensitization is ineffective unless carried out before the Timothy-grass pollen is in the air? If not, can you tell me the best way to carry out desensitization? The patient is 27 years old and is severely affected, though he has not suffered from hay-fever before this year.*

A.—Desensitization is probably the best treatment for this patient, presuming that he has been shown to be sensitive to pollen. Desensitization may be attempted by either the co-seasonal method or the rush method, but the former is the one recommended. In the co-seasonal method treatment is begun with 10 to 20 units of pollen along with 0.2 to 0.3 c.cm. of 1 in 1,000 solution of adrenaline hydrochloride. Injections are repeated daily, the dose being increased by 20 units until a maximum of 80 units is reached. After relief occurs the frequency of injections may be reduced to every two or three days. Increase in symptoms would suggest that the level of dosage was too high. For the rush method patients should be admitted to hospital under the care of an experienced allergist and treated in a pollen-free room. Treatment is begun with minimal doses, as in the routine method, but the injections are repeated every one to four hours and the number of units is increased as rapidly as possible, until a final dose of several thousand units is reached. Unless adequate skill and facilities are available rush therapy should not be attempted, particularly during the pollen season.

Penicillin for Acne Vulgaris

Q.—*Is penicillin cream a better remedy for acne vulgaris than the old-time treatments with zinc lotions, x rays, etc.? If so, how is the treatment applied?*

A.—Acne vulgaris is often regarded as a physiological rather than a pathological condition because of its presence—perhaps as no more than one or two blackheads—in the majority of adolescents. Its full development seems to depend upon the combination of an age-endocrine factor and a seborrhoeic skin, the second part being favourably influenced by sulphur, *x* rays, etc. Secondary infection in acne is an accidental rather than an essential part of the acne "formula"; where this occurs, and if it is due to a penicillin-sensitive organism, then a penicillin cream containing from 200 to 1,000 units per gramme is of some benefit. In the present state of knowledge it would thus seem that penicillin can have no more than an ephemeral effect—a view open to modification upon wider experience.

INCOME TAX

Expenses Allowance

"DELTA" is in full-time employment receiving a salary and bonus and in addition "an annual allowance of £100," apparently in view of the fact that he maintains a house in London to which he returns for the week-ends. In the past this allowance was not assessed, but since "pay as you earn" came into operation tax has been deducted from it.

⁂ The deduction of tax (whether correct or not) is not the final test; an assessment will presumably be made in due course, as in past years, and on receipt of a notice of that assessment "Delta" will see whether the allowance has been included in the amount assessed. If it has, he can lodge an appeal; if it has not the notice will presumably show an over-payment of tax and inform him how the excess can be recovered. Section 26 of the Finance Act, 1942, provided a special deduction (maximum £10) for expenses of this nature, and it may well be the case that the £100 is correctly chargeable subject to the statutory deduction of £10.

Expenses in Connection with Different Appointments

H. P. holds an appointment for which he draws a fixed salary. He has, with permission, accepted two other appointments, one of which at least will entail travelling and hotel expenses, in addition to work at his residence. What expenses can he claim?

⁂ So far as the travelling and hotel expenses are concerned H. P. will have no claim in law, owing to the restriction of allowable expenses under the Schedule E rules to expenses incurred wholly, exclusively, and necessarily in the performance of the duties of the office. The point has been taken to the Courts more than once—e.g., Cook *v.* Knott in 1887, and Ricketts *v.* Colquhoun in 1924—and it is an accepted principle that such expenses are incurred not "in the performance," etc., but anterior to the performance and in order that the individual concerned may put himself in a position in which he can perform his duties. As regards expenses at the residence, the basic question seems to be what additional expenses are in fact incurred (or what portions of the domestic accommodation are relinquished) in order to carry out the duties of the additional appointments. Possibly some small allowance could be claimed and, if necessary, supported by explanations.

Retirement from Colonial Service

F. F. inquires as to the basis of calculating the "£45" tax mentioned in a reply to "Colony" in our issue of Feb. 17, 1945.

⁂ On the facts as stated to us the only income expected to be received in the United Kingdom in the year ending April 5, 1946, was a proportion of a "salary," and £45 was the estimated amount of tax payable thereon.

Tax Due on Share of Partnership Profits

M. has recently ceased to be a member of a firm and has agreed to pay tax on his share of the income for the last year. The share amounts to £605 after deducting expenses. What is the amount of tax due on that sum?

⁂ Assuming that the whole of M.'s allowances are available to be set against this particular income—i.e., that no part has been absorbed by being set off against some other income—the calculation is as follows:

	£	s.	d.	£	s.	d.
Amount of profits £605 less £45 wear and tear ..				560	0	0
Deduct :						
Earned income relief	56	0	0			
Personal allowance	140	0	0			
Children allowance	100	0	0			
				296	0	0
				264	0	0
£165 @ 6s. 6d. in the £	53	12	6			
£99 @ 10s. in the £	49	10	0			
				103	2	6
Life assurance relief £13 @ 3s. 6d.				2	5	6
Net tax due				£100	17	0

Part-time Employment

F. M. is employed in part-time posts in two clinics. He does no private work. Can he claim deductions for (*a*) the cost of travelling to and from the clinics, (*b*) subscriptions to the B.M.A., etc., and (*c*) purchases of medical books.

⁂ The earnings are assessable under Schedule E and the stricter rule as regards expenses applies. The answers are therefore (*a*) No; (*b*) No, unless membership of the associations in question is required by the terms of his employment; (*c*) No.

Sale of X-ray Apparatus

E. H. bought an *x*-ray apparatus in 1930 for £250; he has since received allowances for wear and tear amounting in all to £75 and has now sold it for £100—leaving him in the position of having lost £250–(£75+£100=) £175, i.e., £75 for which he has had no allowance.

⁂ If he replaces the apparatus he can claim a deduction of £75 as "obsolescence"; otherwise no allowance is legally due. The allowances for wear and tear in past years have clearly been inadequate, and if E. H. cannot claim "obsolescence," he may be able to induce the inspector of taxes to reopen the past year's assessments and increase the past allowances.

Examiner's Fees

C. B. acts "from time to time as an examiner for the General Nursing Council and the Central Midwives Board." Are these fees assessable under Schedule D or Schedule E?

⁂ An examinership can frequently be regarded as an appointment or employment, in which case the fees are legally assessable under Schedule E. In any case, however, if the examiner is engaged in general professional work, the income-tax authorities are willing to regard the fees as falling within Schedule D so that they can conveniently be included in one general return. This, however, does not affect any legal right the examining body has of deducting tax under the "pay-as-you-earn" system. If that is being done C. B. had better put the facts before his inspector of taxes.

"Cash" or "Bookings" Basis

W. B. ceased doing panel work a few years ago, but has recently rejoined the panel and now has a substantial number of panel patients. He has lodged an appeal against his assessment, claiming that he is entitled to calculate his gross income on a cash basis.

⁂ It has to be remembered that the cash basis has no legal validity. The correct basis for the gross income is the amount earned, less a reasonable allowance for probable losses by bad debts. Industrialists, traders, and others are refused the cash basis, but by long-standing practice it is allowed in the special case of medical practitioners because of the difficulty in such cases of estimating the loss by bad debts. But that concession applies only where a practice is proceeding normally, in which case the cash receipts can be assumed to give about the same result. In the case of a new practice or a large and sudden addition to the gross earnings of a practice (as in W. B.'s case), the value of the bookings exceeds the amount of the cash receipts, and the legal basis properly applies. In the circumstances we should not expect W. B. to succeed in his appeal.

LETTERS, NOTES, ETC.

Safe Milk for Children

Dr. W. A. Lethem (Ministry of Health) writes: In your issue of June 9 (p. 829), under the heading "Safe Milk for Children," you say that legislation has been passed which will eventually make it compulsory for all milk to be pasteurized except that from T.T. and "accredited" cows. No such legislation has been passed. *Defence Regulation 55G* named certain milks which alone might be sold in "specified areas"—but no such area has yet been specified, and even if any are before the Regulation is annulled they will not cover the whole country. The raw milk to be sold in such areas was T.T. milk and accredited milk *from single herds*, not accredited milk generally, most of which is bulked and therefore cannot be traced to its source. This was admittedly a concession to the small farmer with his own milk round.

⁂ According to the White Paper on milk policy issued in 1943, "the Government proposes to schedule areas in which it will be an offence to sell milk retail unless it is (1) heat-treated as defined by Order, (2) lawfully sold as T.T. milk, or (3) 'accredited milk' sold by a retailer who sells the milk of a single 'accredited herd.'" In a debate in the House of Lords on July 27, 1943, Lord Woolton said that "within the next few months they [the Ministry of Food] would be able to increase the amount of pasteurized milk from 65% by another 15%, and that in a year from that time—eighteen months from now [i.e., in January, 1945]—they would be able to cover the whole of the country *in which they had introduced rationalization schemes*. The problem before the Government was to get sufficient new plant to deal with this increased quantity of milk. Broadly speaking, the rationalization schemes would deal with all the places where there was bulked milk." (Our italics.) On the basis of Lord Woolton's statement, the answerer of the question assumed that compulsory pasteurization would be gradually extended to milk that was not accredited or from T.T. herds. But if, as Dr. Lethem states, areas have not yet been specified, we have yet another melancholy example of the reluctance of the Government to protect the people at the cost of offending one section of a particular trade. Surely one visit to an orthopaedic hospital or children's sanatorium should convince any politician of the need for rigorous and immediate action. American troops in this country are not allowed to drink milk which is not from T.T. herds and is also pasteurized, which is the only milk which may be sold in most of the United States.—Ed., *B.M.J.*

Swaddling and Thumb-sucking

Mr. John A. McCluskie, B.Sc. (Royal Infirmary, Aberdeen) writes: I have been interested for some time in the practice described by Dr. S. H. Waddy (April 14, p. 529) of the binding of infants in swaddling clothes. May I call attention to some observations made by W. and M. G. Dennis in the American *Journal of Genetic Psychology* in 1940. The cradle board used by the Hopi Indians restricts movements of arms and legs to a severe degree. This practice does not increase the infantile mortality rate, and the infants do not even show any evidence of hyperactivity or rage reactions, which are the usual psychiatric result of restraint of movement. The reverse would appear to exist: in children over a year old attempts were made to return to the board during emotional tension. W. Dennis in the *Trans. N.Y. Acad. Sciences* in the same year stated that there was no evidence that swaddling in cradles produced either restlessness or rage reactions. His opinion is that so long as no purposive activity is thwarted, no reaction follows. On the other hand, there is considerable evidence that thwarting thumb-sucking by swaddling produces considerable reaction. But the widespread practice among midwives is closely allied to that of the Hopi Indians, and there is much to be said for it, although, as your correspondent indicates, it can be a dangerous practice, and I think it is one which would repay detailed investigations. Some experiments have been made with chickens which show that it is possible to control the development of habits—e.g., feeding with a dropper controls the pecking urge—so that binding in certain cases associated with replacement of the sucking habit by something else might very well be a way out for the thumb-sucking baby. Should we look to the biologists for that "something else"?

Penicillin and Other Drugs

Major A. J. Cameron (R.A.M. College, Millbank) writes: In the *Journal* of June 16 (p. 864) I have read with considerable interest the letter from Major C. F. Garfit, of Lahore, referring to my medical memorandum on penicillin in ocular therapeutics which appeared in the *Journal* of Feb. 17 (p. 222). The answer to his query is "yes." The preparation of adrenaline used was the liq. adrenalin. hydrochlor. *B.P.* For myself I was not aware that it contained 0.5% chlorbutol, nor do I know what the effect of that drug is upon the sensitivity of penicillin. It is, I agree, a point of some interest, and I should like to know; but, as Major Garfit says, it is the liq. adrenalin. hydrochlor. which is used in practical ophthalmology most times.

Doubtful Penetrating Abdominal Wound

Dr. Reginald Fisher (King's Langley) writes: Referring to Brig. Charles Donald's article (June 9, p. 802) on the above subject, may I mention a point that may help in these cases—a memory of the last war. When *x*-ray screening for foreign bodies I often noticed that if they were in the peritoneal cavity they were motionless (except sometimes in the liver), while if in the abdominal wall they moved freely with respiration.

An Eyeless Needle

Mr. J. L. Aymard writes from Berlin, C.P., South Africa: My method has been for some two years past to take from a bundle of horsehair a single strand and one which tapers to a thin portion. A fine hypodermic needle, even a dental one, is broken off at its junction to the base holder. The thin end of the hair is threaded down the shaft from the eye; as soon as the strand wedges then it is withdrawn a little, cut off, and redrawn into the shaft. This same needle can be used over and over again. I have found the above very useful in fine plastic work and trust others may do likewise.

Herpes and Varicella

Dr. H. E. Gibson (South Godstone) writes: The relation between herpes and varicella seems very complicated. Unlike Squad. Ldr. H. R. E. Wallis (April 21, p. 580), I had chicken-pox as a child, and again at 26. I have just had a patient who suffered from herpes at 42, and three weeks later her younger daughter, aged 7, developed chicken-pox.

Miss E. Sylvia Pankhurst, honorary secretary of the Princess Tsahai Memorial Hospital Fund (3, Charteris Road, Woodford, Essex) asks physicians and surgeons who would be willing to accept a position on the staff of this hospital in Addis Ababa, Ethiopia, to communicate with her, so that she may lay their applications before the honorary medical committee. The chairman of the Fund is Lord Davies, and the honorary treasurer Lord Horder.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 21 1945

THE EFFECTS OF HIGH ALTITUDE ON MAN*

BY

B. H. C. MATTHEWS, C.B.E., Sc.D., F.R.S.

LECTURE I

Dr. Oliver founded these lectures in memory of William Sharpey "to promote physiological research by observation and experiment and to encourage the application of physiological knowledge to prevention and cure of disease and the prolongation of life."

The subject of the present lectures is the application of physiological knowledge to the saving of life and to increasing the efficiency of flying personnel. As an example, enemy fire is an obvious risk to which aircrews are often exposed, but, flying at 25,000 feet, many thousands of men are constantly exposed to other less obvious physiological dangers to life. At this height the atmosphere is lethal to men acclimatized to sea level, so that they must be protected by oxygen equipment. The intense cold is another danger, from which they are protected by special clothing and equipment. The physiological risk, anoxia, is an unseen enemy, present continually, from which aircrews must be protected not only by oxygen equipment but also by training to make them realize the nature of this danger and its effects. If they have to crash-land, the hazards of sudden deceleration can be greatly reduced by the application of physiological knowledge embodied in crash procedure and body harnesses. In tight turns the effects of centrifugal forces on the circulation can be minimized.

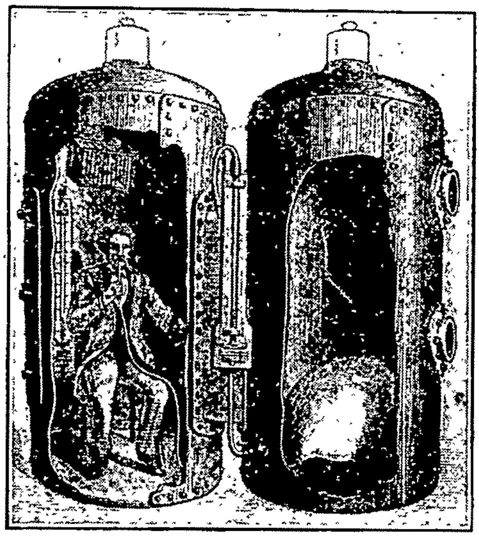

FIG. 1.—Paul Bert's decompression chamber.

Research on physiological problems of flying has been carried out intensively in all Allied countries; the Germans also were early in the field, and large funds and facilities were available for the purpose from 1933 onwards. The Flying Personnel Research Committee, under the chairmanship of Sir Edward Mellanby, was set up by the Secretary of State for Air before the outbreak of the war; it initiated intensive investigations for the R.A.F. by R.A.F. medical officers and civilians, working both in the laboratory and in the field, to carry out basic research and organize its application to aircrews. The Americans gave much help before Pearl Harbour, but since then they have provided almost unlimited facilities for research in the physiology of flight. Research in Canada and Australia has been very active, and the results are of great value. It is impossible to give credit here to the many research workers involved. Free interchange of information has taken place between the Allies, and much of the resulting success has come from team-work by men from all the Allied nations.

The field of aviation physiology is wide, and here two subjects are chosen: (1) the effects of high-altitude flying; (2) the effects of mechanical stress.

Physiological Effects of High Altitude

These can be divided into: (1) the effects of lowered partial pressure of oxygen at high altitude; (2) the effects of the lowered atmospheric pressure. The first leads to incomplete saturation of the blood with oxygen, and may indirectly disturb the carbon dioxide content of the blood. The second may lead to bubble formation within blood vessels and tissues, and also to effects following expansion of the gas present in the viscera, sinuses, middle ear, and, after chest injuries, of air within the pleura.

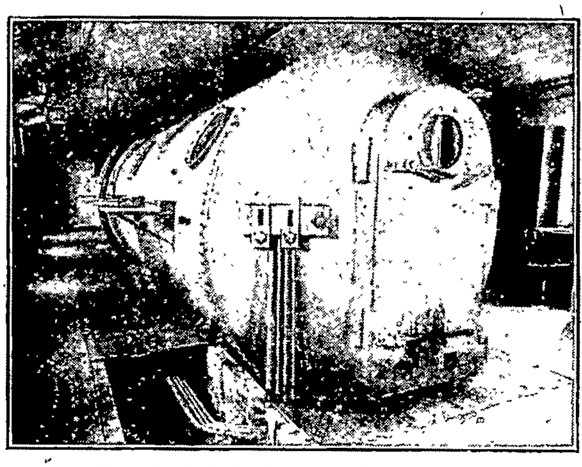

FIG. 2.—R.A.F. decompression chamber.

Anoxia

Anoxia is not a new problem; the effects of oxygen lack on man were encountered both on mountains and in balloon ascents before the beginning of the last century, but modern research on this subject was initiated by Paul Bert after the disaster in 1875 to the balloon "Zenith," in which Tissandier's two companions lost their lives from anoxia, although oxygen for breathing was carried in the balloon. Paul Bert (1878) built the first decompression chamber (Fig. 1), in which low-pressure air conditions could be studied on the ground, and this was followed by the work of Haldane, Barcroft, Henderson, and Flack, which, in addition to elucidating the nature of anoxia, shed much light on the normal processes of respiration. While many physiological studies have been carried out in flight, the greater part of our exact knowledge comes from studies made in decompression chambers (Fig. 2) at sea level or in mountain expeditions, as the conditions for research and experiment are not easily met with during flight. It is necessary to draw a sharp distinction between the mountaineer who has had days or weeks to acclimatize to low air pressure and the aviator who usually starts from ground level and is rarely away from it for more than 12 hours. An altitude of 28,000 feet has been reached on Mount Everest by men not using oxygen equipment; the same height may prove fatal to an aviator in about half an hour.

---

* The first of two Oliver-Sharpey Lectures before the Royal College of Physicians of London, March, 1945.

The accompanying table sets out the major effects of oxygen lack as they are seen in the aviator. There are three primary factors determining the intensity of symptoms: (1) the oxygen partial pressure of exposure; (2) the duration of exposure; (3) the muscular activity of the subject. At heights up to 35,000 feet all symptoms are entirely prevented by breathing pure oxygen or air enriched with oxygen (Col. VII of table).

Effects of Oxygen Lack on Man

I	II	III	IV	V	VI	VII
Altitude; Oxygen p.p., mm. Hg.	Approx. Blood Saturation (%)	Effect	Time for Full Development	Unconsciousness	Death	Approx. O_2 Percentage in Inspirate for Normality
5,000–10,000 ft. 126·5–104·5	95–90	Reduced night vision	Over 1 hour	Never	No	28%
10,000–15,000 ft. 85·8	90–78	Fatigue, headache, errors of judgment, and indifferent mental condition	Over 1 hour	Very uncommon, and only with hard work	No	35%
15,000–18,000 ft. 77·5	80–68	More pronounced mental errors. Reduced capacity for physical work	30 min.	Incidence less than 1% if at rest	Only in pathological subjects	42%
18,000–22,000 ft. 64	70–55	Gross mental abnormality. Euphoria or drowsiness and lethargy. Loss of neuromuscular co-ordination	15 min.	Unconsciousness may occur above 20,000 ft. Dangerous, especially in single-seater aircraft	Rare, but possible with other adverse conditions (cold, etc.)	50%
22,000–27,000 ft. 51	Less than 65	Rapid loss of muscular control, often with uncontrollable twitching, especially if some hyperventilation	10–2 min.	Individual variation in time for onset of unconsciousness, 5–30 min.	Death likely at 27,000 ft. in less than 1 hour	70%
27,000–30,000 ft. 45		Rapid loss of consciousness, 1–5 min.			Death probable in 20–60 min.	80%
30,000–37,000 ft. 32		Unconsciousness in ½ to 2 minutes			Death to be expected in less than 30 min.	90–100%
37,000–44,000 ft. 24		Breathing 100% oxygen, anoxia present. Severe at 44,000 ft.				
Over 44,000 ft.		Only safe with pressure cabin or pressure suit				

The effect of changing from oxygen to air at 35,000 feet is to produce unconsciousness in less than a minute. Respiratory failure is to be expected after about 7½ to 8 minutes and death in about 10 minutes. At 25,000 feet the same change leads to a progressive development of symptoms. The first symptoms seen are cerebral; subjects are often euphoric within two minutes. Failure of the nervous and muscular co-ordination follows. The electro-encephalogram (Beigel *et al.*, 1942) parallels the clinical reaction to anoxia; slow waves are observed as the subject becomes unconscious, and spike activity during convulsive seizures. There are often intensive peripheral vasodilatation and great acceleration of the heart just before unconsciousness occurs; alternatively, some subjects show collapse of the cardiovascular system before becoming unconscious. Unconsciousness and loss of muscular tone may ensue in about 5 minutes. Death is unlikely to occur in less than 30 minutes, but there is a possibility that it may follow longer exposure.

The danger of an oxygen breakdown and death of a member of the crew in large R.A.F. aircraft is reduced by telephonic communication, maintained at regular short intervals from the captain to all his men, and very few deaths attributable to anoxia have occurred. In the U.S.A.A.F., which has had to operate under different conditions, the considerable number of deaths from this cause enables lethal exposure to be deduced to an approximation. Death is unlikely to occur below 22,000 feet and may occur in a few minutes above 27,000 feet (see Col. VI of table). A number of necropsies have been performed on those who have died from anoxia, and 27 are described in a recent paper by Kitzler (1944). These show little pathological change except a great congestion of the lungs, viscera, and, particularly, the kidneys.

A man breathing air at 30,000 feet remains conscious for little more than a minute, and it will be appreciated how rapidly aircrews must act if their oxygen equipment should fail at these altitudes. In large bomber aircraft the crew are provided with small portable oxygen sets, so that they may carry out duties which necessitate walking any considerable distance in the fuselage. In fighter aircraft the high-altitude pilot carries in his parachute packing an emergency oxygen set which can not only be used in emergency but which goes with him to supply oxygen during descent, should he have occasion to use his parachute. Otherwise he may become unconscious while falling and fail to pull his parachute rip-cord.

Anoxia of gradual onset is extremely insidious in that the subject is usually quite unaware that anything is wrong. His behaviour appears normal to himself, but to others may be that of a drunken man. In the last war, cases of the bombing of friendly targets occurred owing to anoxia. It is for this reason that the R.A.F. have put into operation large numbers of mobile decompression chambers. In these, aircrews can be shown what happens if they neglect to use oxygen properly; this is done at ground level in safety under the supervision of a medical officer. This familiarization of aircrews with the proper use of their oxygen equipment probably accounts for the very low incidence of oxygen failures in the R.A.F.

Subjects vary greatly in their reaction to lack of oxygen, and these differences appear in part to be connected with the varying sensitivity of individual respiratory centres to oxygen lack. The respiratory centre and carotid sinus are primarily controlled by the carbon dioxide in the blood and, to a secondary and much more variable extent, by the oxygen tension. Some subjects placidly pass into coma and unconsciousness with increasing altitude with very little rise in the respiratory minute-volume and without muscular movement. Others show considerable hyperventilation, which often enables them to resist a greater degree of anoxia than the former class, but may then exhibit violent involuntary movements, sometimes extending to a generalized convulsion before they become unconscious. The lowering of carbon dioxide by hyperventilation in the latter class appears to be responsible for the very marked difference in their symptoms (Schmidt, 1943). When oxygen is administered to subjects who have become unconscious, unless a low flow is used at first they may pass through a phase of convulsion and twitching before returning to normality. Recovery can be very rapid, and the subject is practically unaware, a minute later, of what he has been through, provided the unconsciousness has been of short duration. Moreover, if pure oxygen is given to a subject on the verge of collapse it may produce complete collapse for some 30 seconds, followed by a very rapid recovery. While the biochemistry of this is not fully established, it probably is a reaction to the sudden change of acidity in the blood which will result from rapid conversion of reduced haemoglobin to oxyhaemoglobin (the Bohr effect).

In the last war, pilots often flew at 18,000 feet without using oxygen. Anoxia was then regarded as one of the normal stresses of flying, and pilots were required to pass an anoxia-tolerance test. In this they breathed from a closed spirometer, the carbon dioxide being absorbed and the oxygen tension falling progressively. Those who showed early pulse irregularities or fainting were rejected. This is now no longer necessary, as anoxia is a stress which can be removed with proper oxygen equipment, and all who are fit on clinical examination are able to fly to at least 25,000 feet when using that gas. In R.A.F. aircraft the use of oxygen is compulsory above 10,000 feet, and below that at night for some aircrews. Between 10,000 and 15,000 feet there is no gross danger if not used; but experience has shown that not only is a man less mentally alert and his range of vision reduced if he does not have oxygen at these heights, but he subsequently suffers considerable fatigue if exposed to slight anoxia for several hours; this is avoided by the employment of oxygen. Moreover, without oxygen he "blacks out" more easily in a tight turn.

It is well known that prolonged oxygen-breathing at ground level may produce pulmonary oedema, and, as Paul Bert first showed, at pressures greater than atmospheric it may produce convulsions. The dangers of oxygen poisoning do not exist, as this gas is used in aviation at reduced pressures. No difficulties from this cause have arisen. Oxygen equipment for air use has to meet stringent requirements. It must be of minimum encumbrance to the wearer and require the minimum of his attention. All the Allied Air Forces use oxygen stored in cylinders, for although liquid oxygen in thermos containers can save weight, and was so employed both in the last war and subsequently by the R.A.F., its disadvantages—evaporative loss and the difficulty of controlling the flow to requirements—have rendered it less suitable than oxygen in cylinders for use in the rough-and-tumble of operational flying. The weight of the cylinders introduces the question of economy in the use of oxygen. All Air Forces employ systems in which the flow of oxygen to the mask is interrupted during expiration, as the consumption when this is done is little more than one-third of that needed with a constant flow. Apparatus must be able to supply a flow sufficient to cover the physiological requirement for any physical work that aircrews may have to undertake. A liberal rating is necessary to cover both this and the rapid ventilation that may occur during the stress of combat. Figures for ventilation rates of aircrews taken during bomber operations show an increase in areas of danger.

A man at 18,000 feet, though still conscious, becomes very sluggish mentally. He is incapable of physical exertion and may become unconscious if he attempts it. In contrast to this, men who have become acclimatized over a period of weeks are able to lead a normal life at 17,000 feet and to carry out hard physical work. There are three major changes which make this possible:

1. The red blood corpuscle count rises by up to 50% and the oxygen-combining capacity of the blood increases with this.
2. The ventilation rate progressively increases, the alkalosis resulting is compensated by the kidneys, and the acclimatized man is able to breathe rapidly, with approximately normal *p*H of the blood.
3. There are changes in the tissue-oxidase systems which enable cells to work normally in spite of the reduced oxygen pressure in the blood reaching them. For example, in animals the concentration of myoglobin in the diaphragm is approximately doubled with acclimatization.

On return to sea level acclimatization is lost by a reversal of these changes, occupying a fortnight or more; artificially induced acclimatization (Rühl, 1943)—e.g., by ingestion of ammonium chloride—has not been very successful.

At heights above 18,000 feet little further acclimatization appears to take place, and the experience from mountain expeditions has been that above 20,000 feet men deteriorate in physical condition, sleep very little, are capricious in their diet, and ways lose weight. It may be conjectured that the chemical ocesses of digestion and metabolism are unable to proceed rmally at the low oxygen partial pressure which occurs under se conditions. Discontinuous exposure to altitudes of 10,000 14,000 feet, as may occur in pilots who are not using oxygen, s not lead to any very significant acclimatization. In one y of the blood of civil airline pilots not using oxygen a in the red blood count was found (Clinton and Thorn, 1943). ausea and respiratory distress, commonly seen in mountain ess, are much less prominent in short exposure to oxygen this fact appears to be due to slowness in lowering the by hyperventilation in the early stages of acclimatization Compensation 2, above, has occurred, and those symp- must be attributed to this, acting concurrently with anoxia, recalling Mosso's early hypothesis, now discarded, that loss of CO_2 was the primary cause of mountain sickness.

Effects of Low Pressure per se

The dangers of compressed-air illness have long been recognized among under-water and caisson workers, but it is only recently that the parallel effects that may occur at pressures below atmospheric have been recognized and studied. Symptoms occurring at low pressure that could not be attributed to lack of oxygen are found in the literature of exposure to low pressure (e.g., Jungbluet), but were first fully described by Armstrong (1939). Intensive research has been carried out since then to elucidate the nature of decompression sickness as it occurs at reduced atmospheric pressure.

There is a great difference in the conditions leading to decompression sickness in the diver and the aviator. The diver spends his life at the lower pressure (atmospheric) and a short time at the higher pressure when under water. Consequently nitrogen reaches and goes into solution only in certain tissues readily accessible to the circulation, and does not attain a high pressure in inaccessible tissues—for example, the optical media of the eye. In diving, the pauses during ascent necessary to allow nitrogen to escape from the lungs are a small multiple of the total time spent submerged at high pressures. In contrast, the aviator spends his life at the high pressure (atmospheric), and his exposure takes place when he ascends to great altitudes. It is just from those tissues which do not become saturated with nitrogen in diving that escape of nitrogen is most difficult in the case of the aviator. One of the commonest sites of bubble formation at reduced pressure is the synovial fluid of joints, from which gas has difficulty in escaping owing to very low vascularity, and bubbles can often be seen by *x*-ray examination at low pressure. The first description of decompression sickness was by Robert Boyle, who saw a bubble within the eye of a viper when he decompressed it to a pressure equivalent to that at about 50,000 feet.

In general the symptoms are less severe and of slower onset than those seen in divers. Moreover, they disappear at once on descent to 20,000 feet. There are three main factors responsible for the formation of bubbles in the blood vessels and tissues at lowered pressure: (1) the ratio of pressures, and to a lesser extent the absolute magnitude of the pressure change; (2) the rate of change: this is of great importance in diving, but the rate to avoid aerial bends is so slow that gradual ascent to avoid symptoms is impracticable; (3) local conditions in the tissues which may precipitate formation of bubbles—e.g., exercise. While the bubbles in divers are primarily composed of nitrogen, those occurring in aviators contain a high proportion of carbon dioxide.

From theory and experiments on divers the late J. S. Haldane deduced that a change of pressure in a ratio of 2 : 1 at least was necessary before bubble formation could take place, and this appears true at reduced pressures, as decompression sickness is never seen below 20,000 feet. Above 30,000 feet it becomes increasingly common, and the symptoms are of increasing severity. The symptoms usually develop gradually, starting with muscular and joint pain, with pain in the chest followed by sensory symptoms, and anaesthesia of limbs; itching and tingling sensations are common. These may be followed by a collapse of central origin in which the subject suddenly becomes intensely white, the pulse may slow and become imperceptible, and consciousness is lost. On immediate increase of pressure to 20,000 feet recovery takes place in a few minutes, though delayed neural reactions, of which the commonest are visual scotomata (Engel *et al.*, 1944), and, rarely, epileptiform convulsions, may appear subsequent to return to ground level, and in rare cases death has occurred after severe chest symptoms (Goggio and Houck, 1945). In these, massive hydrothorax and pulmonary oedema have been found at necropsy.

The incidence of symptoms is extremely variable in the same subject between daily exposures, and between different individuals. This is a matter of great practical importance, but intensive research has so far failed to locate the fundamental biochemical factors involved. As in divers, overweight and obese body build are unfavourable. There is evidence of symptoms increasing with age (Thorne, 1943), but some subjects seem completely immune from bends at pressures corresponding to

40,000 feet. It is at present impossible to predict liability to bends from other physical characteristics, and it has therefore been necessary to select flying personnel for very high altitude work by tests carried out in a decompression chamber with two or three exposures on different days for each subject. At present we cannot foretell how long the selection will remain reliable. Protection against bends is possible by breathing oxygen before exposure to low pressure—to dispel nitrogen from the blood and replace it by oxygen, which can be used up within the body when the pressure falls. By pre-breathing oxygen for several hours a very high degree of protection against bends is obtained. This has obvious practical difficulties for flying personnel, and can be employed only on missions working to a prearranged time-table. In practice, where available to crews, it is little used, as after selection they very rarely experience decompression symptoms in the air.

In early work the central effects were attributed to raised C.S.F. pressure resulting from bubble formation; but while the escape of gases from C.S.F. is very slow—as shown by McArdle (1945) on oxygen-breathing human subjects from whom C.S.F. was withdrawn for analysis by lumbar puncture—animal experiments have not revealed any great rise in C.S.F. pressure which can be attributed to internal bubble formation. Moreover, little rise in intracranial pressure occurs in man (Peterson *et al.*, 1944). It is most probable that the central effects follow local interruption of circulation by bubbles in blood vessels in the brain. That the peripheral symptoms of pain or itching have a peripheral origin was proved by Squad. Ldr. Pask in a number of cases in which the application of pressure to the affected limb with a special pressure bag removed the symptoms.

Change of Pressure

With rapid change of pressure the sinuses and middle ear must equalize their pressure with that outside; otherwise, symptoms may result from congestion and exudation with rising pressure, or cessation of circulation with falling pressure. This is a matter of great practical importance, as the maintenance of a healthy E.N.T. condition in aircrews is necessary for them to fly without any discomfort. The subject of otitic barotrauma has received much attention in the R.A.F. (Dickson *et al.*, 1943), but sudden change of pressure has no other physiological effects, and, provided the Eustachian tubes are patent, a fall of pressure of half an atmosphere in about half a second can be tolerated by man without any discomfort. Studies on this explosive decompression were first carried out by Armstrong and Heim, and later extended by the R.A.F. It was found that even such a severe change of pressure produced no discomfort in normal subjects. On the other hand, with increasing pressure air must be admitted to the middle ear by opening the Eustachian tube, and this cannot be done rapidly enough to tolerate descent at anything like this rate. Most aircrews can clear their ears by swallowing or by jaw movements, so that they can descend at 4,000 to 10,000 feet a minute without discomfort. (Expansion of gas in the viscera is rarely a practical source of difficulty in high flying.) All personnel can operate to 25,000 feet without oxygen; selected aircrews can operate to about 40,000 feet. Above this height it is essential to apply pressure all over the body surface either by a pressure suit (Marshall, 1937) such as was employed by Adam in 1937 when he took the altitude record to 54,000 feet, or a pressurized cabin or a pressure gondola such as was used in the U.S. Army high-altitude balloon flight to 72,000 feet.

For civil use high-altitude flying has many advantages. It enables aircraft to operate fast and economically, to fly over the weather, and to fly in smooth air. It seems certain that pressure-cabin aircraft will ultimately be employed for all long-distance travel. Passengers inside will not then need to wear oxygen masks to avoid anoxia; nor would they incur the risks of decompression sickness or experience the discomforts of rapid pressure change on their ears. It therefore becomes a matter of engineering to overcome the physiological stresses of altitude to which man has been subjected since the start of flying.

It is interesting to turn to the work of Paul Bert, written in 1877, to see his recommendations on oxygen for aeronauts. "Aeronauts planning very lofty ascents ought in the preceding days to avoid nervous and intellectual fatigue. Before starting they should take meals of substantial food and take with them some cheering victuals to eat frequently on the way. To be safe it is necessary only to breathe the air whose oxygen content rises proportionately as the pressure falls, and I cannot recommend too strongly that at 5,000 or 6,000 metres a direct and compulsory connexion be made between the oxygen bags and the mouths of the aeronauts." Much of the physiological work for the R.A.F. during this war has been directed towards putting Paul Bert's recommendations into effect.

IRREPARABLE VESICO-VAGINAL FISTULA IN IRAQ

TREATMENT BY URETEROCOLOSTOMY

BY

DONALD M. DOUGLAS, M.B.E., M.B., Ch.M., M.S.Minn., F.R.C.S.

Professor of Clinical Surgery, Royal Faculty of Medicine, Baghdad, Iraq; First Assistant in Surgery, British Postgraduate Medical School

Thirty centuries before the birth of Christ the Sumerians, living on the banks of the River Tigris, recorded their deeds in writing, maintained an army for their own defence, and drank a "liquid closely resembling beer" (Lloyd, 1943). But in spite of this admirable beginning Iraq was but an outlying province of the decadent Ottoman Empire at the outbreak of the First Great War. She was loosely governed by corrupt officials, who were satisfied in the discharge of their duties if a sufficient revenue was extorted from the country and a sufficient quota of conscripts was obtained for the Turkish Army. The real power in the country lay in the hands of the great Kurdish and Bedouin sheikhs, to whom social reform and social services made no appeal.

To-day, a mere 20 years since the foundations of independent Iraq were laid, the structure of a universal health service is well established, its two main pillars a thriving medical school and a school of nursing. But a sad legacy of centuries of ignorance and neglect remains. Tuberculosis is rife, and in every tow and village the hideous ravages of smallpox, trachoma, leishmaniasis, and venereal disease are evident. The infantile mortality in country districts is over 50%.

It is with the results of neglect in pre-natal and natal ca that this paper deals. In the smaller towns and villages, ar in the desert, women are attended during childbirth by th relatives. Hospital care, even when available, is not used unl the relatives consider that life is in danger. This is in p due to distrust of hospitals and in part to the great difficul of transport in the desert. As a result women may lie in ch birth for seven to ten days without any skilled attention w soever, and large fistulae between the bladder and ante vaginal wall may occur from prolonged pressure of the fo head.

Material of the Present Series

During the last three years 29 cases of vesico-vaginal f have been admitted to the gynaecological wards of the Hospital, Baghdad. Of the 29 cases 25 came from ou villages or the desert. In all of them the infant was sti The average time in labour was about 120 hours, but six were known to have been in labour for over 168 hours a for 240 hours. As a rule the infant was extracted manu an unskilled woman in the desert, although six cases had had a forceps delivery in a provincial hospital.

Eleven of the 29 cases were admitted to the surgical wards for ureterocolostomy. All the 11 were judged by the department of gynaecology to be irreparable, and most of them had had one or more attempts at plastic repair. The age of the patients varied from 18 to 40. On the whole the physical health of the women appeared to have suffered very little, although in one case a persistent pyelitis was present. But mentally they were miserable and life was a burden to them. Their clothes were permanently soaked in urine, their vulvae and thighs excoriated and raw, and an all-pervading ammoniacal odour caused them to be shunned by their fellows. It is a striking witness to their misery that, in a land ridden by religious superstition, where a mullah's amulet is trusted more than medical advice, none of these patients refused this very considerable two-stage operation.

Pre-operative Care

The renal function was investigated by intravenous pyelography to demonstrate the presence of two functioning kidneys and by the estimation of the blood urea. Urea-clearance and concentration tests are of course impossible in these cases because of the leak of urine from the fistula. In only two instances was there any evidence of impairment of renal function: Case 4 showed a left renal calculus and Case 9 a mild bilateral hydronephrosis with pyelitis and a blood urea of 56 mg. per 100 c.cm.

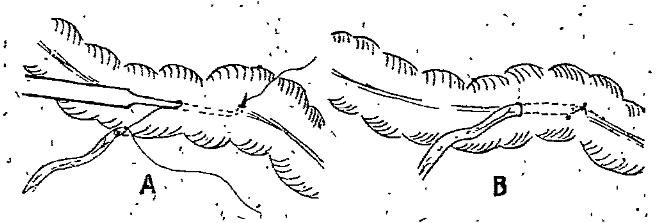
In attributing this renal dysfunction to the fistula one must bear in mind the fact that urinary bilharziasis is extremely common in Iraq, and consequent strictures of the intramural part of the ureter are very often met with. It is possible, and even likely, that in a series of 11 hospital admissions taken at random just as high an incidence of mild renal dysfunction might be detected.

Preparation of the Colon.—If sulphasuxidine had been available it would have played an important part in the preparation of the colon, but in its absence our efforts were directed towards obtaining a dry and empty colon in which to implant the ureter. This was achieved by withdrawal of food for 24 hours before operation and the avoidance of enemata within 12 hours of operation. In practice, a purge was given on the evening of the second day before operation, a wash-out the following morning, and no further food. On the evening before operation a low enema was given. This routine gave satisfactory results.

Operation

Anaesthesia.—General anaesthesia was preferred to spinal analgesia in these cases, for a purely technical reason. Under spinal analgesia it was found that the bowel remained in tone and peristaltic waves were frequent, during which the bowel was contracted to a firm rope-like structure. When in this condition it is very difficult to introduce the all-important anchoring suture and later the enfolding layer of sutures. Under general anaesthesia, on the other hand, because of the intact sympathetic inhibitory reflex pathway, the bowel is relaxed and atonic, and the whole operation is simplified.

Technique.—The operative technique followed was that of Grey Turner (1943), with one major modification (see Fig.).



Method of introducing the ureter into the lumen of the colon. (A) A cleft-palate needle carrying the anchoring suture is passed into the lumen and downwards for 1½–2 in. and out again. (B) The broad shank of the needle dilates a round hole in the bowel through which the ureter can subsequently be passed.

Instead of incising the bowel to introduce the ureter, the wall of the bowel was pierced with a cleft-palate needle carrying the anchoring suture. As the needle was pushed down the lumen for some two inches its broader shank dilated the hole in the bowel wall, into which the ureter fitted snugly. The round hole so made did not tend to tear widely as an incision does, and the risk of leakage is perhaps minimized thereby. The anastomosis was made extraperitoneal, so far as was possible, by bringing a flap of posterior parietal peritoneum over it; but this manœuvre was by no means always successful, and one patient died of peritonitis from a leaking suture line. All cases were dealt with by a two-stage technique, the interval between the two stages usually being about a month.

Double Ureter.—In two cases a double ureter was encountered, in both on the right side. On the first occasion one was rather at a loss as to what course of action to adopt, but a moment's thought showed it to be a comparatively simple matter. The anchoring suture was inserted through adjacent walls of the two ureters and loosely tied, and thereafter the procedure was as in a normal case, both ureters being inserted through the same hole in the bowel wall.

Post-operative Care

On returning to the ward an intravenous drip infusion of 0.45% saline was instituted and kept going for 48 hours. No fluid was allowed by the mouth for 24 hours. Sulphathiazole was given in 1-g. doses every four hours for the first three days with the object of preventing renal infection in the immediate post-operative period. As a rule the bowels moved with a fluid urinous motion about the third day—but sometimes no urine was excreted for as long as eight days. This suggests strongly that occasionally suppression of renal function may take place after the operation, either reflexly or by blocking of the ureter by oedema. After the second stage, urine was excreted from the bowel almost invariably the first day.

Mortality

Two of the 11 patients died. Post-mortem examination revealed that peritonitis was the cause of death in both cases. But the cause of the peritonitis was not the same in both cases. In Case 3 there was sloughing of the lower end of the ureter at its point of entry into the bowel. This was without doubt due to clumsy technique on my part in dealing with a difficult and obese subject. It was hard to get a sufficient length of ureter mobilized to introduce it without tension into the bowel because of the great amount of fat in the retroperitoneal tissues and pelvic mesocolon. Hence the ureter was stripped too far back and separated from its mesentery for too great a distance, thus being deprived of its blood supply.

The second death occurred in the ninth case in the series, after the second stage. Post-mortem examination showed that the suture line in the colon had failed to heal adequately and a faecal leak had occurred. A diffuse peritonitis resulted, and death ensued on the eighth post-operative day. It is of interest that these two deaths occurred in the two oldest patients in the series. Both were over 40 years of age.

Complications

Pyelitis was the commonest complication. It occurred in 5 of the 11 cases, but it would perhaps be scientifically more accurate to say that it occurred in 5 of the 22 kidneys. The time of onset of the pyelitis is interesting. It appears constantly between the 8th and 14th post-operative days. It was evidenced by raised temperature and pulse, pain in the loin, rigors, and rectal frequency. The last-named is a distressing symptom noted by Grey Turner, and suggests that a proctitis from infected urine is as easily produced as cystitis. The symptoms yielded readily enough to the administration of sulphathiazole, though in one case it was necessary to resort to intravenous dosage. This patient was seen six months after operation, and although her general health was good she still had rectal frequency of about six times a day.

Abdominal Distension.—Mild paralytic ileus was common and was often accompanied by vomiting, but no satisfactory explanation was ever found for this. It is possible that a degree of peritoneal soiling occurred in many cases in spite of scrupulous packing off of the suture line. Another possible explanation is that retroperitoneal dissection is necessary to mobilize the ureters, and the tendency to ileus after retroperitoneal operations is well known.

Discussion

The nine survivors were among the most appreciative and grateful patients I had in Iraq. They were able to return to their husbands and homes and begin a normal life again. It can be realized what that meant when one remembers that their average age was between 18 and 25 years. Nevertheless a far more efficient follow-up system than is possible in Iraq is necessary to compute the end-results of the operation. In Grey Turner's series some patients survived for 20 and 30 years. The mortality of 2 deaths in 11 cases makes the operation one of considerable hazard, certainly not to be undertaken lightly. But the lot of a patient with an incurable vesico-vaginal fistula is such a miserable one that I believe it to be justified. In more skilled hands the mortality is likely to be considerably lower.

Summary

Eleven cases of ureterocolostomy for incurable vesico-vaginal fistula are described. The operative modification whereby incision of the bowel is avoided is described.

There were two deaths in the series, both from peritonitis; the remaining nine patients returned to active life.

It is a pleasure to acknowledge the great help and advice given by Brig. C. Naunton Morgan in this series, the stimulation and practical assistance of the writings of my teacher and chief, Prof. Grey Turner, and the data of Prof. M. McDowall, of the department of gynaecology, Royal Hospital, Baghdad. Dr. Kadhim Shubbar, Dr. Najibal-Yacubi, and Dr. Ghanim Akrowie were of the greatest assistance in pre- and post-operative care.

OTITIS EXTERNA

BY

J. F. BIRRELL, M.D., F.R.C.S.Ed.

T/Major, R.A.M.C.

Otitis externa is one of the most common conditions met with in any ear-nose-and-throat department. This is especially true in the Army over-seas, where it may account for one-quarter of all aural cases, or one-sixth of all E.N.T. patients examined. There are many problems connected with the disease that are worthy of study, and, indeed, many to which there is as yet no answer. This report is mainly based on nearly 1,000 cases of otitis externa seen in the Army. Furunculosis and dermatitis of the auricle are not discussed in any detail, but are mentioned briefly as coexisting affections.

Aetiology

The disease does not respect age or rank. It may occur in children and persist at intervals throughout life. The mechanism appears to be twofold. A meatal congestion is set up, causing irritation, which is attacked by the patient, who scratches the ear voluntarily or involuntarily, or by the doctor, who attempts to diagnose, treat, or remove the cause of the irritation. The result is a break in skin continuity, through which normally present saprophytic or invading pyogenic organisms may enter and cause trouble.

The meatal congestion may be caused by (i) irritants which enter the meatus from the middle ear, (ii) the natural secretions of the meatus, (iii) irritants entering the canal from the outside, (iv) general conditions predisposing to skin infections, or (v) local or general allergy. A brief consideration of the anatomy of the external meatus will show how easy it is for foreign material of all kinds to reach the canal, how difficult it may be for such matter to find its way out once it has reached the downward-sloping inner half of the meatus, and how simple it is to injure the meatal skin in an attempt to remove the irritant. Daggett (1942), in a valuable article, has drawn attention to the deep anterior meatal recess as a reservoir which may retain pus and debris.

The irritant entering the meatus from its inner end is pus, associated with an active otitis media. The meatal floor is constantly bathed in pus, the organisms of which welcome any disruption in the epithelial surface through which they may enter and multiply.

Wax and sweat are the natural secretions of the external meatus. Wax is secreted by the ceruminous glands of the outer half of the meatus, lines the canal, separates from the walls apparently by the movements of the mandible, and works its way out, bringing with it desquamated epithelium. Unskilled attempts to remove the wax by a match, a Kirby grip, a knitting-needle, or some such similar article may abrade the skin. Similarly, the meatal epithelium may be lacerated by the tip of an aural syringe, especially if the wax is hard and difficult to remove. After syringing, the canal should be thoroughly dried with wool or gauze, and the walls painted with spirit, or the retained solution, if hypotonic, may macerate the skin. In the same way the epithelium may suffer during the removal by scoop, curette, or syringe of the tightly adherent mass of cerumen and epithelium called keratosis obturans, which in its milder forms is more common than is often realized. Sweat may be produced in excess in hot weather, and may, by the discomfort it causes, lead to scratching of the ear. It may cause a matted condition of the hair at the outer end of the meatus, and this in turn results in irritation.

Many things may be introduced into the meatus through its outer end. One of the most common, particularly in soldiers serving over-seas, is salt water, and in the "tideless" Mediterranean the water is permanently dirty in frequented beaches. Daggett, while discounting sea-bathing as an important aetiological factor in desquamative otitis externa, points out that in the heat of the day the water will be evaporated from the meatus, leaving a deposit of salt which may increase skin maceration by hygroscopic action. In Italy these swimming ears presented such a characteristic appearance that one came to regard them as a specific infection.

Cotton-wool or paper may be pushed into the meatus and forgotten—for example, by gunners who use these substances as ear-plugs against muzzle blast. After some weeks the meatal skin reacts to the breakdown of vegetable matter by producing an otitis externa which is often most acute. Dust and sand may be blown into the meatus and, mixing with wax and sweat, cause irritation. Insects, such as the bed-bug or the maggot, may find their way into the canal and, by their movement, scratching, or biting, may set up a most acute infection. Lastly, infection may be transmitted by the finger from some other part of the body.

Chemicals may act on the meatus by a direct burn, such as occurs with caustics, acids, hydrogen peroxide, vesicant gases, etc., or by a local allergic reaction, such as is seen with sulphanilamide powder in susceptible people. Insufflation of sulphanilamide powder was a common practice in the Tunisian campaign, but was discontinued in Italy as a result of adverse reports from otologists. The powder tends to form a hard caked mass, and otitis externa occurs in a significant number of cases.

General conditions which predispose the skin of the meatus to infection are seborrhoeic dermatitis, especially of the scalp, and relapsing furunculosis. It is possible that vitamin deficiency may produce the condition, although there is no positive evidence as yet. In recent years much thought has been given to allergic conditions of the ear, and otitis externa of purely allergic origin has been described.

Bacteriology

Friedman and Hinkel (1941), studying a series of 200 cases, found that in every instance more than one organism was present, and that the commonest were *Staph. albus*, diphtheroids, *Ps. pyocyanea*, and micrococci. Furthermore, they stated that in those cases which most resisted treatment no single organism predominated. A study of 25 normal ears showed the same group with the exception of *Ps. pyocyanea*. Daggett reported that diphtheroids, either alone or in combination with *B. proteus*, *Ps. pyocyanea*, or *Staph. albus*, were found most frequently in 49 cases. In this hospital *Ps. pyocyanea* was obtained as the predominant organism in nearly every case in which a swab was taken. An effort was made to swab the ears of patients showing different varieties of the condition in the hope of being able in future to diagnose the predominant organism from the clinical appearances. This hope was not fulfilled. Apart from the constant presence of pure *Ps. pyocyanea* with green pus in the meatus, no association could be discovered. The subsidiary organisms were the same as those found by Daggett.

Varieties

The condition is usually described as being of two types—wet and dry—but this is inadequate for a proper understanding of the disease. The earliest manifestation is meatal injection. When infection supervenes there is desquamation of the meatal epithelium and pus formation. In some cases this is more acute, and is associated with a marked oedema of the meatal walls. Prolonged or recurrent infection leads to a hypertrophy of the epithelium, which is thrown into ridges. The various stages may be called congestive, exudative, oedematous, and hypertrophic; or the varieties named mild, acute, acute oedematous, and chronic hypertrophic otitis externa. Some cases, however, do not fit into this picture. There is the fungous infection, in which the debris resembles wet blotting-paper; the membranous variety, commonly found after sea-bathing, in which the membrane probably contains salt; and the granular type, in which granulations may form on the meatal wall and spread on to the intact drum.

Symptoms

The earliest complaint is of itching or irritation, which may be so severe as to be unbearable. In the congestive stage this is the only symptom. Then discharge appears—at first watery, but later becoming purulent and finally a cheesy debris as the pux mixes with desquamated epithelium. A purely external infection never results in a mucopurulent discharge, as there are no mucous glands in the meatus. Pain may be felt, depending on the amount of tension under the epithelium and the speed with which the tension is set up. Meatal skin is tightly bound down to perichondrium, and thus a furuncle or acute meatal oedema may cause extreme pain. The discomfort is referred, as a rule, to the region of the parotid gland and to the jaws, and is aggravated by any movement of the temporomandibular joint.

Where the middle ear is normal hearing is not affected, but if the meatal lumen is occluded by oedema or debris deafness may be complained of. Other symptoms are a feeling of swelling in the ear, associated with a slowly produced oedema; and dermatitis when the infection spreads to the auricle.

Appearances

It is important to examine the auricle before inspecting the meatus, as the diagnosis can often be made before a speculum is inserted. In a very large proportion of cases the skin of the anterior incisura, between the tragus and the lower anterior end of the helix, will show infection—a small crust, a fissure, or a small raw area. Where this is found the diagnosis of otitis externa is certain, although there may be a coexisting otitis media. Dermatitis of the auricle from an otitis media alone is found in the line of the pus—along the meatal floor, the floor of the concha, and via the incisura intertragica to the skin of the fissure between the lobule and the angle of the jaw.

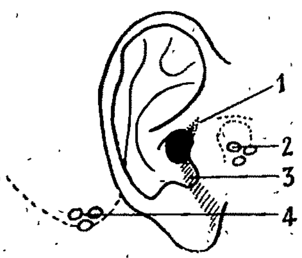
In the external meatus congestion is the earliest sign of trouble. It often affects the floor about the junction of cartilaginous and bony meatus. In the exudative stage the meatus contains a varying amount of pus and desquamated epithelium. This must be carefully and gently mopped away with wool-tipped probes, particular attention being paid to the anterior meatal recess. A light wire probe and a light touch are the secrets of success in this manœuvre. The probe should be held so loosely that the finger and thumb will slip along the shaft if the tip is impeded in any way. One must remember that the skin lining the inner half of the meatus is extremely sensitive to the touch. Thorough cleansing is essential for accurate diagnosis and successful treatment, and, while mopping under direct vision is ideal, the same result can be achieved by blind mopping if care and patience are exercised and frequent examinations with the auriscope made to determine how much secretion is left. In cases in which the epithelial debris is difficult to remove it is often helpful to moisten the tip of the mop with 20% sodium sulphate solution.

When the meatus has been cleaned the epithelium will be found to be rough, red, and desquamating. The outer surface of the drum may share in this process, leading one to suspect an otitis media. In the acute oedematous type the narrowed meatal lumen is obvious. Pain will be experienced on insertion of the speculum, and no attempt should be made to force its passage. Mopping—necessarily blind mopping—should be carried out as described. An estimate of the amount of oedema can be obtained by comparison with the other ear if it is healthy. The narrowing of the lumen in chronic otitis externa is much more resistant to the passage of a speculum than in the oedematous cases. This is due to hypertrophy rather than pain. Pus and debris will be found, and there is often a coexisting perichondritis of the auricle.

Regional adenitis may be present, the glands involved being situated in front of the tragus or over the tip of the mastoid process. Systemic upset varies a good deal. Some patients have no general disturbance, while others look ill, feel ill, have a raised temperature and pulse rate, show a furred tongue, complain of loss of appetite, and have difficulty in sleeping.

Differential Diagnosis

Diagnosis must be made from otitis media (see Fig.) and, if pain be present, from mastoiditis. The criterion in distinguishing between otitis externa and otitis media is the appearance of the drum, and, as the two conditions often coexist, one is not justified in ruling out otitis media until every part of the drum has been inspected for perforation. In many cases perforation in an oedematous congested membrane is found only after a diligent search. A purely external otitis is suggested if the hearing is good and there is no mucus in the discharge. The presence of mucus can be tested for by leaving a wick of ribbon gauze, soaked in 5% lead acetate solution, in the meatus for 24 hours. On removal, if mucus is present in the discharge the innermost end of the wick will be found to be black, while if the discharge is purely external in origin no colour change will be seen. This test has been used in doubtful cases for a year now, and has proved most reliable.



1. Auricular spread in otitis externa. 2. Anterior auricular glands. 3. Auricular spread in otitis media. 4. Posterior auricular glands.

The diagnosis between otitis externa and mastoiditis is often difficult. Both conditions result in otorrhoea with pain, both may be associated with constitutional upset, and in both the mastoid region may be tender and oedematous. In mastoiditis tenderness is maximal on deep pressure, especially over the mastoid antrum, while in otitis externa tenderness is maximal on superficial pressure over the glands at the tip of the mastoid process. In external infection, also, there is tenderness on pressure over the tragus or on movement of the auricle. *X*-ray examination of the mastoids will show no abnormality if the middle ear is normal and if there is no post-auricular oedema.

Prognosis

The prognosis in any attack of otitis externa is good, a cure being effected in 2 to 14 days, depending on the severity of the infection: 60 to 70% of cases are healed within a week. Where chronic otitis media is present as well, healing takes longer, although the meatal infection should clear up in three weeks. Dermatitis of the auricle in association with otitis externa does not materially lengthen the time for healing in most cases, provided adequate treatment is given.

Unfortunately, relapses are common. The percentage of cases which recur cannot be measured accurately in the Army, as patients discharged from hospital do not necessarily stay in the locality, and thus an otologist cannot follow up his cases.

A relapse means either that treatment has been inadequate or that reinfection has occurred. No particular organisms appear to be responsible. Chronic otitis media is often the cause of a relapse. Frequent recurrences or lack of treatment lead to chronicity which, once established, is well-nigh impossible to cure.

Treatment

Brain (1942) stressed that "treatment should be governed by two important facts. The first is that our protection from external irritants and infections depends upon a dry and intact horny layer, and treatment should be designed to maintain it. . . The second fact of therapeutic importance is that living cells are instantly damaged by water or by grossly hypotonic solutions, and this applies to the skin when the protective stratum corneum is missing, or its continuity is disrupted by exudation."

Treatment resolves itself into two approximately equal parts—the thorough cleansing from the meatus of all particles of discharge, and the application of lotions to the inflamed meatal walls. The mechanism of mopping has been described, and its importance cannot be too strongly emphasized. Drugs are applied to the infected skin on wicks of ribbon gauze or painted on by means of wool-tipped wire probes. The ribbon gauze wick must be inserted gently so that it maintains contact with the walls in the whole length of the meatus. It should be changed daily, and some authorities moisten the wick with the appropriate solution every 12 hours. Cotton-wool adheres to the raw skin surface and should never be used. The selected solution must be non-irritant and isotonic; it should not stain the meatal walls or leave a deposit thereon; it should not dry enough to cause pain on removal. Pastes and powders allow infection to spread under them.

An acute oedematous otitis externa must first have the oedema reduced to permit complete cleansing of the drum and the deep anterior recess. Then the inflamed epithelium must be healed and finally dried and hardened. The drugs used for reducing oedema are 20% sodium sulphate, 8% aluminium acetate, or 10% ichthyol in hypertonic saline. The first two both tend to dry off during the course of 24 hours and are thus painful to remove. The ichthyol preparation has been used by me for nearly three years, and has proved most efficacious. After 48 hours' treatment the case usually resembles one in the exudative stage.

In this stage numerous solutions may be used to heal the skin. Those already mentioned may be persevered with, or one may try 10% ichthyol in water, 10% ichthyol in glycerin, 5% lead acetate, 10% argyrol, or calamine lotion. Of these, ichthyol in water dries quickly and is painful to remove; calamine lotion leaves a deposit on the skin which obscures the view of the progress; lead acetate has the same fault to a lesser degree, but has considerable healing properties, and is, in my experience, more efficacious than argyrol, which is superior for inflamed mucous membranes. Ichthyol in glycerin is probably the best all-round treatment, being soothing and easy to insert and remove.

When no further exudation is found the case resembles one in the congestive phase. Here a paint of 1% silver nitrate or 1% alcoholic solution of gentian violet should be used to harden the meatal skin. The latter solution stains the meatal skin and should not be employed until all discharge has stopped. It is the best treatment for fungous infection and for the granular type. When pus is green, or if *Ps. pyocyanea* predominates without green pus, 1% acetic acid, or a mixture of 1% acetic acid and 10% ichthyol, will give good results, although some patients find them uncomfortable, and they tend to dry off.

Pain is best treated with heat—fomentations, kaolin poultices, or hot-water bottles—and sedatives. The patient under treatment should be instructed not to scratch the ear, however itchy, and not to let water enter the meatus during washing. He should be told specifically not to use cotton-wool as a plug while the ear is discharging, as this only increases skin infection. Sea-bathing is forbidden for several months.

If a dermatitis of the auricle is present, good results are obtained with 1% ammoniated mercury in Lassar's paste applied on spreads and moulded to the pinna. Five per cent. sulphathiazole paste was efficacious, but was discontinued when it was found to produce local reactions and even generalized sensitivity to light.

The question of chemotherapy in otitis externa is a vexed one. Many patients had had a course of one of the sulphonamide drugs before reaching hospital, with no benefit to the local condition. One has seen cases in which penicillin has been given parenterally for wound infections, furunculosis, or the aural condition itself, and yet otitis externa persists. The reason is obvious. Otitis externa is a mixed infection, and most of the causal organisms are insensitive to penicillin and the sulphonamides.

Syringing the ear in a case of otitis externa is always liable to increase the infection; but it is necessary sometimes when the secretion in the anterior meatal recess is too hard for mopping. To leave this debris is to invite recurrence. I have been in the habit of syringing these cases on the first day on which the ear is dry, and treating with ichthyol in hypertonic saline or ichthyol in glycerin for a day or two before going on to the paint.

It is with pleasure that I record my thanks to Col. C. H. K. Smith, O.B.E., *M.C.*, commanding officer of a general hospital, for permission to publish this article.

PENICILLIN GROWN FROM A NUTRIENT MEDIUM PREPARED FROM POTATO EXTRACT

BY

J. O. GAVRONSKY, M.D.

The production of penicillin is rapidly growing. This is likely to continue for some time to come. Other antibiotics in application to agriculture, horticulture, and veterinary surgery will soon have to be produced on a large scale, possibly on a scale exceeding the production of penicillin. Under these circumstances the question of preparation of nutrient media becomes of great importance.

Conditions for growing moulds, to obtain the needed product of their metabolism, vary with the mould one is dealing with. To a large extent the result depends on the nutrient medium used. This medium must be both satisfactory and cheap. With very few exceptions the composition of such media is kept secret. In making known the composition and mode of preparation of a nutrient medium used by me I cannot claim to get a higher content of penicillin in the metabolic solution than that obtained in some of the media already used. I can only say that the titre of penicillin compares favourably with that obtained by using Czapek-Dox medium with the addition of yeast or corn-steep liquor, or by using the medium introduced by Challinor and McNaughton. The preparation of the medium is as follows:

Method

Potatoes or potato peelings are hydrolysed in twice the quantity of tap-water with 2% of HCl on the weight of potatoes. The hydrolysis proceeds for 2¼ hours at a pressure of 3 atmospheres. After filtering the hydrolysate through a linen cloth an extract is obtained with an average glucose content of 5.5%. The sugar content naturally varies with the starch content of the potatoes or potato peelings used. In the case of potato peelings, unless they are used soon after peeling, a longer time is needed for hydrolysation. In the case of potatoes, these are washed and cut into pieces of approximately 1/2 to 2 cm. thickness. The necessity for cutting is avoided by using potato peelings.

The quantity of extract thus obtained from 1 kg. of potatoes with 2 litres of water and 20 c.cm. of strong HCl, after disposing of the solid residue by wringing out the linen bag used for filtering, is approximately 2,450 c.cm. This extract is diluted to 4% glucose content. We thus obtain 3,360 c.cm. approximately. The *p*H is roughly adjusted to neutral to litmus. Corn-steep liquor is added, 370 c.cm.—that is, 10% of the total quantity of medium. $NaNO_3$ is added—3% per litre; and activated charcoal—1/2% on weight of potatoes. The *p*H is adjusted to 6, and the medium sterilized in the autoclave for a time, depending on the bulk of medium in preparation. While it is sufficient to have a litre flask containing 200 c.cm. of medium for 10 minutes at 1 atmosphere, a 5-litre aspiration bottle filled with medium requires three-quarters of an hour at 1 atmosphere pressure. It is advisable to add to the medium 10% of water to allow for evaporation in the autoclave.

This medium, when ready, is of a dark-brown colour. The addition of 1/2% of activated charcoal clarifies it to a certain extent. Fortunately, the waste water, after extraction of penicillin with amyl acetate, retains the bulk of the pigment, so that ultimately a powder is obtained with a degree of freedom from pigment corresponding to the stage of purification. Nor are these pigments, or other impurities derived from the medium, toxic: 1/2 c.cm. of sodium salt of 2,500 units per c.cm. injected into three mice did not seem to affect them adversely.

The titre of the crude penicillin solution obtained by using this medium, tested by serial dilution or ring method, frequently exceeds 60 units per c.cm. The average titre is above 30 units per c.cm. The highest figures obtained by me when using the Challinor and McNaughton medium were in the neighbourhood of 25 units per c.cm. I did not get up to this level with the Czapek-Dox medium.

Discussion

Apparently a nutrient medium prepared in the way described, besides containing all the glucose and most of the nitrogenous foodstuffs needed by a growing mould, must contain certain activating substances. By chemical analysis the nutrient medium was found to contain all the inorganic salts entering into the composition of Czapek-Dox salts except $MgSO_4$ and $NaNO_3$. The addition of $MgSO_4$ was shown by comparative experiments to be unnecessary, while $NaNO_3$ definitely improved the titre of penicillin. Corn-steep liquor certainly has a beneficial effect. In comparative experiments, while a flask containing hydrolysed potato medium would show at its height a titre of 15–20 units per c.cm., a flask containing medium to which corn-steep liquor has been added would show 60 and up to 80 units per c.cm. Before sterilization the addition of a small percentage of pulp made from cabbage, or particularly carrots, seems to have a beneficial effect. As the height of titre constantly varies from day to day, and from experiment to experiment, I have not yet been able to draw definite conclusions as to the effect of such additions.

I need not enter into details of the actual cost of my medium. The economy is obvious—always on condition that the titre should not be lower than that of the other media used, and it does not seem to be so.

At present I have three experimental vessels—apparatus for penicillin production by surface growth in a continuous process —working at Highgate Hospital laboratory. From the seventh day—that is, from the time of the titre approaching its height —the average titre of all three tanks is 34.5 units per c.cm. What is the cost of this medium per litre? It amounts to the cost of 100 c.cm. of corn-steep liquor, 3 g. $NaNO_3$, 1 g. activated charcoal, and the potato peelings, which I get either from a hospital kitchen or from any canteen in the neighbourhood—free of charge. Working on a large scale, the additional cost would be the transport of potato peelings or diseased potatoes to the factory. True, on a farm one may use the peelings for feeding pigs, but the market value of it would hardly exceed 10s. a ton. One must therefore expect that agricultural waste will ultimately play an important part in the preparation of media for the production of various antibiotics.

I am much indebted to Dr. J. M. Alston for his constant interest and help in my work on antibiotics, and I must thank the London County Council and Dr. J. R. Reed for enabling me to work at Highgate Hospital.

The Federation of the British Legion has approved a recommendation of the Council of Management of the British Legion Village for the appointment of 21 medical men as honorary consultants to Preston Hall, Maidstone, Kent; the British Legion Sanatorium, Nayland, Colchester, Essex; and Douglas House, Bournemouth, the convalescent seaside annexe of Preston Hall. During the absence of Dr. J. B. McDougall (medical director of the British Legion Village), who is now attached to U.N.R.R.A., Dr. Frederick Heaf has been appointed honorary consulting medical director. The consultants will form a medical committee under the chairmanship of the honorary consulting medical director to advise the Council of Management in all medical matters connected with the British Legion Village.

HYPERSENSITIVITY TO TRANSFUSED BLOOD

BY

SHEILA CALLENDER, M.D., M.R.C.P.

R. R. RACE, M.R.C.S., L.R.C.P.

AND

Z. V. PAYKOÇ, M.D.

A patient who is believed to be suffering from the rare disease called lupus erythematosus diffusus required a series of transfusions on account of persistent anaemia. As a result of these transfusions a remarkable succession of antibodies has appeared in her serum. The patient's red cells are Group O, M, P, Rh_1Rh_1, and negative with the three "new" antibodies to be described. She has never been pregnant.

Transfusions

	Date	Donor's Name	Donors' Groups			
			Rh	Anti-Lutheran	Anti-Willis	Anti-Levay
1	Feb. 2, 1944	Marshall	Rh_1rh	—	—	—
2	Aug. 19, 1944	R. B.	rhrh		Unknown	
3	Aug. 19, 1944	Lutheran	rhrh	+	—	—
4	Sept. 23, 1944	Willis	Rh_1Rh_1	—	+	—
5	Sept. 29, 1944	Mules	Rh_1rh	—	—	—
6	Oct. 6, 1944	Howes	Rh_1Rh_1	—	+	—
7	Nov. 7, 1944	Levay	Rh_1Rh_1	—	—	+
8	Nov. 20, 1944	Allington	Rh_1Rh_1	—	—	—
9	Jan. 31, 1945	"	Rh_1Rh_1	—	—	—

Anti-Lutheran = The patient's serum taken at the end of Aug., 1944.
Anti-Willis = The patient's serum taken in Oct., 1944.
Anti-Levay = The patient's serum taken in Nov., 1944.

A specimen of serum taken shortly after the Lutheran transfusion was found to contain the rh agglutinin called St (γ Fisher); the "incomplete" form of this antibody was also present. More interesting, however, was the finding of another separable agglutinin, called anti-Lutheran in the table. The red cells of 8–9% of the English population, irrespective of the ABO, MN, P, or Rh groups, are agglutinated by this antibody. The Lutheran antigen is inherited as a dominant Mendelian character. The statistical and family evidence will be presented in detail elsewhere.

The St and anti-Lutheran antibodies gradually disappeared, their titre being low at the time of the September and October transfusions. After the Willis, Mules, and Howes transfusions a second "new" antibody—anti-Willis—appeared. The donor Howes's blood presumably assisted in this immunization, for Howes also has the Willis antigen. The Willis antigen is inherited as a dominant Mendelian character independent of ABO, MN, or P but not independent of Rh, and it is now practically certain that it is controlled by another allele at Fisher's C-c locus (Race, 1944), which may be called C^w. The Willis antigen is present in about 7% of Rh_1Rh_1 bloods, and the relative frequencies of the three alleles in the English population must be about C 43.5%, C^w 1.5%, and c 55%. Again the evidence for this interpretation will be presented elsewhere.

After some weeks of existence anti-Willis faded from the patient's serum, but towards the end of this period Levay's blood was given. This blood also proved to be incompatible, for about 14 days later a weak agglutinin—anti-Levay—was evident. The Levay antigen is a rare one and probably also a "dominant," for so far it has been found only in the blood of Levay and in the blood of this donor's father, but not in several hundred random bloods examined. All three "new" antibodies are more active at 37° C. than at lower temperatures.

Attempts to immunize one volunteer to the Lutheran antigen and two to the Willis have so far had no success. As the Lutheran and Willis antibodies may not be reproducible, and as the supply of antiserum is limited, it is proposed to deposit the names and addresses of as many of the Lutheran and Willis positives as are willing to help at the Bureau of Human Heredity, 115, Gower Street, London, W.C.1. It is hoped with the help of Major Moloney, of the U.S. Army Medical Corps, to make some equivalent arrangement with people whose homes are near New York. If either of these antibodies do turn up again, as they are sure to do, sooner or later, it may be possible to correlate the present work.

Comment

There are two points of general interest in this history. First, the patient must be extraordinarily sensitive to antigenic differences, and this supports the hypothesis that the symptoms of the disease lupus erythematosus are manifestations of some undetected antigen–antibody reaction. Secondly, given such a hypersensitive recipient, a glimpse is obtained of the multiplicity of red cell antigens which may be found in the future. One familiar and three "new" antibodies have been made to the blood of eight donors, although considerable care has been taken to use appropriate blood. Landsteiner was of the opinion that blood groups would some day be known to be as individual as finger-prints.

Our thanks are due to Prof. Cappell and Prof. Fisher for continued interest and encouragement; to the donors for permission to use their names; and to the patient, who has been very co-operative.

A CASE OF NOCTURNAL HAEMOGLOBINURIA

BY

JOHN A. MILNE, M.B., Ch.B.

House-physician, Western Infirmary, Glasgow

(From the Gardiner Institute of Medicine, University of Glasgow)

The syndrome of paroxysmal nocturnal haemoglobinuria with haemolytic anaemia was first recorded by Marchiafava and Nazari in 1911, and according to Wintrobe only 41 cases had been described in the literature up to 1943.

Case Report

The patient, a Royal Marine aged 27, was admitted from a naval hospital for special investigation to the wards of Prof. J. W. McNee in the Western Infirmary, Glasgow. He was complaining of anaemia, with frontal headaches, tiredness, and weakness. He entered the Navy 8 years ago and his only illness was in Oct., 1943, while in the Faroe Islands. It was characterized by diarrhoea, vomiting, and urticaria, which was diagnosed as food poisoning. He has never had malaria. He is married and has one healthy child aged 21 months. There is no history of anaemia or jaundice in the family.

In March, 1944, the patient began to suffer from frontal headaches while working. These persisted unless he sat down and rested for a short while. These headaches gradually increased in severity, and he noticed that he was becoming very easily tired and breathless on exertion. In May, 1944, he reported sick, and was admitted to a naval hospital, where he was found to be profoundly anaemic. Three weeks later he developed a painful tongue and tender bleeding gums. The condition yielded rapidly to large doses of ascorbic acid, and glycerin and borax applied locally. For the anaemia he received iron and a variety of liver preparations without any improvement. When he had been two months in hospital he was given one pint of blood, with slight improvement in haemoglobin level. A month later he was given another pint of blood of correct group, after which, for the first time, his urine was noticed to be very dark in colour for two days following the transfusion. He was admitted to the Western Infirmary on Dec. 9 for special investigation, as the exact diagnosis of the anaemia remained uncertain.

On admission he was seen to be a pale well-nourished man with a slight icteric tinge of the skin and sclerotics; a few discrete hard lymphatic glands were present in both axillae and groins. The heart, lungs, and nervous system showed no abnormality. The liver and spleen were not palpable.

Blood Picture.—The following investigations were made, using the technique described by Wintrobe. Haemoglobin was estimated by means of a photo-electric colorimeter. Erythrocytes, 3,060,000 per c.mm.; leucocytes, 2,400 per c.mm.; haemoglobin, 11.4 g. per 100 c.cm.; packed-cell volume, 32.5%; mean cell volume, 106 $c.\mu$; mean corpuscular haemoglobin concentration, 34.8%; reticulocytes, 12.5%. Differential leucocyte count: neutrophils, 44.5%; eosinophils, 2.5%; lymphocytes, 48%; monocytes, 4%. A film stained with Leishman's stain showed anisocytosis, slight poikilocytosis, and macrocytosis of the erythrocytes. There was no evidence of malaria parasites or pigmentation of leucocytes.

On sternal puncture marrow was easily obtained; it appeared to be hypoplastic, as the film made from it contained numerous fat spaces. A few primitive erythroblasts were seen, but the marrow was definitely normoblastic. The blood plasma gave a positive indirect van den Bergh reaction—0.7 mg. of bilirubin per 100 c.cm. The fragility of the patient's erythrocytes to saline was within normal limits, haemolysis starting at 0.45%. Wassermann reaction, negative. A fractional test meal showed a normal hydrochloric acid curve. The urine contained a quantity of urobilin. At this point a haemolytic anaemia was diagnosed, the cause, however, being unknown.

Progress.—One week after admission the patient complained of pain in one of his lower molar teeth. The tooth was extracted under local analgesia on Dec. 18. At 2 a.m. on Dec. 19 he awoke and complained of an ache across his lumbar region, and a specimen of urine passed at this time was noticed to be dark red. Another specimen of urine at 6 a.m. was still dark in colour, while one at 9 a.m. was perfectly clear. The van den Bergh reaction on Dec. 19 showed a positive indirect reaction—1.4 mg. of bilirubin per 100 c.cm. Early on the morning of Dec. 21 he again passed a dark-red specimen of urine, while at 9 a.m. the urine was clear. Examination of the urine showed the colour to be due to a haemoglobin derivative. No erythrocytes were seen. The haemoglobin derivative was identified spectroscopically as oxyhaemoglobin. Since then haemoglobinuria has recurred regularly, the specimen passed in the early hours of the morning being dark red, that passed about five hours later being perfectly clear.

Further Investigations.—(1) The Donath-Landsteiner test was performed in order to exclude haemoglobinuria due to cold; it was negative. (2) In order to determine whether the fall in the *p*H of the blood during sleep was a factor in the production of the haemolysis (Ham, 1939) the patient's erythrocytes and serum were set up against an isotonic system over a *p*H range of 6.5 to 7.0 by Dr. W. B. Kyles, clinical pathologist to the Infirmary. The result was quite negative. (3) Even the clear specimens of urine contained a constant deposit of haemosiderin, demonstrated by the hydrochloric acid-potassium ferrocyanide reaction (Wintrobe). (4) As necrosis of the liver is a feature of this disease (Scott, Robb-Smith, and Scowen, 1938) liver function was estimated by the laevulose-tolerance and Quick's sodium benzoate tests, but was found to be within normal limits. (5) A specimen of serum was examined by Prof. D. F. Cappell; this identified the patient as Group O and Genotype Rh_1Rh_2. (6) In order to bring out the association of the haemoglobinuria with sleep, his sleep rhythm was altered and he slept through the day and remained awake at night. This caused the haemoglobinuria to appear through the day while the patient slept, and was absent at night when he remained awake.

Discussion

The pathology of this disease and the mechanism of production of the haemoglobinuria are fully discussed by Scott, Robb-Smith, and Scowen (1938). The hypothesis put forward for this explanation of the nocturnal haemoglobinuria is the alteration in the *p*H of the blood during sleep (Ham, 1939). While sleep undoubtedly is a factor, as seen by altering the sleep rhythm, the laboratory experiment carried out by altering the *p*H of a specimen of blood, while not conclusive, would tend to point against alteration of the *p*H being part of the mechanism, as the range of *p*H covered was much greater than would occur in the human body. It is known that transfusions and trauma are factors which increase or precipitate the haemolysis. This is well shown in this case.

Summary

A case of chronic haemolytic anaemia associated with nocturnal haemoglobinuria is presented. Blackwater fever, syphilis, and Lederer's anaemia were excluded. The patient was Rh-positive. The existence of the nocturnal periodicity of the haemoglobinuria was confirmed by altering the sleep rhythm, thus indicating that the patient suffered from the Marchiafava-Micheli syndrome.

I should like to thank Prof. J. W. McNee for his permission to publish this case.

The Mothers' Hospital of the Salvation Army in Lower Clapton Road, London, E.5, is entirely staffed by medical women. The report for 1944 is curtailed in the interests of economy, but space has been found for a foreword by Miss Margaret Basden, senior obstetric surgeon, who on the outbreak of war took up residence in the hospital. She writes in moving words of the fine spirit with which the nursing staff and patients and the fire-watchers endured the ordeal of air raids.

Medical Memoranda

A Case of Gangrene of Meckel's Diverticulum

I send the following notes in view of the interesting questions raised by the case.

CLINICAL HISTORY

I was called early one morning to see a man aged 66, who had been in great abdominal pain all night. The pain was widely diffused all over the abdomen, the bowels had been well opened twice the previous day, the temperature was normal, and the pulse 96 and rather weak.

I found a very distended bladder, but the patient expressed no desire to pass water. He had passed it on retiring to bed for the night, after a day during which he had felt particularly well and energetic. (It so happened that I had examined him 10 days previously, when attending another member of the family. He then complained of vague abdominal pain, but there was no question of constipation or urinary difficulty, and palpation showed no abdominal tumour. I accordingly advised *x*-ray investigation if the pain persisted, but within a day or two he stated it had quite gone.)

I gave him morphine gr. 1/6, and ordered a prolonged hot bath. After some thirty minutes he passed about 4 oz. of urine. I then felt able to leave him and went to my surgery. Upon my return he had passed no more urine, and the abdomen was still very distended. I decided to tie in a size 5 Jaques catheter. Visiting him again 6 hours later I found that 30 oz. of urine had come away. He was, however, looking iller than before, the abdomen was still very distended, and I could feel a mass in the abdomen to the left side, which I thought was separate from the bladder.

I felt a further opinion was necessary, and called in a surgical colleague. Unfortunately it was not possible to arrange the consultation for a further 3 hours, and when we visited the patient his bladder had again apparently made it difficult to be certain about the diagnosis of the second tumour. It was decided to take him into hospital, and again slowly drain the bladder. By this time the patient was obviously very ill, but the temperature was still normal, though the pulse had risen to 110 and was "thready" in nature.

Overnight catheterization showed a completely empty bladder, and no urine was secreted for 48 hours. Thus it became evident that the tumour felt was not a distended bladder. An *x*-ray examination of the abdomen brought the following report from the radiologist. "Considerable gas distension of the stomach. No gas distension of the small intestine. No evidence of intestinal obstruction from *x*-ray."

A Ryle's tube was passed, and constant suction applied. After 48 hours he was completely comfortable. Some flatus had been passed after enemata, but he was still markedly distended. The Ryle's tube by this time was discharging considerable quantities of upper jejunal contents, so the evidence of an upper intestinal obstruction was definite.

OPERATION AND POST-MORTEM FINDINGS

Operation was performed under a low-spinal anaesthetic. On entering the abdomen the first findings were two or three pints of blood-stained fluid in the peritoneal cavity. Considerable distension of the jejunum was present and a mass to the left of the umbilicus covered by very adherent omentum. On liberating this mass and separating the omentum a gangrenous Meckel's diverticulum was found; the obstruction was consequent upon the adhesion of the omentum. About 6 in. of the bowel including the gangrenous diverticulum were excised.

At the end of the operation the patient's general condition was moderately satisfactory, but a physician was called in to cope with advancing left heart failure. The next day he seemed to be improving, but suddenly vomited jejunal contents and died immediately afterwards.

A limited post-mortem examination showed gangrene of 1 ft. of the small intestine, proximal to the anastomosis, due to mesenteric thrombosis. The sequence of events appears to be an acute inflammation of a Meckel's diverticulum. This was completely encased in omentum. The bowel was at first partially but later completely obstructed. The gangrene of the proximal loop of bowel after the operation can be explained by an extension of the thrombosis to a main branch of the superior mesenteric artery.

I am hoping that explanations may appear in the *Journal* to account for (1) the acute urinary retention ushering in the illness, (2) the complete anuria subsequently developing, and (3) the acute dilatation of the stomach.

To save space I have omitted various unessential details of the treatment given while in hospital. I am grateful to Mr. R. Trevor Jones, F.R.C.S., for his help with the case, for performing the necessary operations, and for his helpful criticisms of my notes.

Mill Hill, London, N.W.7. D. A. GRATTAN, M.B., Ch.B.

L. E. McCrea (*J. Urol.*, 1945, **53**, 466) records his observations on 581 patients with prostatic hyperplasia of all types. The average age was 63.2 years. Only 19.6% were well after a five-year period, or out of 367 operated on only 31% were in good health.

Reviews

ENCYCLOPAEDIA OF MEDICAL PRACTICE

The British Encyclopaedia of Medical Practice, including Medicine, Surgery, Obstetrics, Gynaecology and other Special Subjects. Medical Progress. London: Butterworth and Co. 1945.

This is the first supplementary volume of the *British Encyclopaedia of Medical Practice* to appear since the lamented death of the General Editor, Sir Humphry Rolleston, but as the publishers declare, "The Rolleston tradition survives," and the general plan he adopted is scrupulously followed. We are further reminded of another loss the profession has sustained during the year by the article on alimentary tract diseases from the pen of Sir Arthur Hurst. Prof. Grey Turner and Prof. Lambert Rogers contribute a valuable review of surgical progress, which is naturally largely based on their war experiences. Dr. Langton Hewer's article on anaesthesia and analgesia emphasizes the advances made in intravenous methods of anaesthesia, which are so much less trying to the patient, but which call for skilful and careful administration. Moreover, intravenous general analgesia offers a hopeful field for research. A slow drip infusion of 0.2% procaine hydrochloride in from 5 to 10% glucose relieves the intense pruritus of jaundice and provides sufficient analgesia for painful burn dressings. Dr. R. D. Gillespie's paper on mental diseases illustrates the reaction from the over-simplification of mental processes that followed too ready an application of Pavlov's conditioned reflexes to them. For the rest he naturally dwells at some length on the influence of war experiences on the mental state. Pulmonary tuberculosis has proved a serious problem in wartime, and Dr. Maurice Davidson contributes a thoughtful review on the subject. He inclines more and more to the opinion that further progress in the control of this national scourge will depend upon study of the soil rather than upon study of the seed; it is a general infection with a local manifestation in the delicate lung parenchyma. Of recent advances in treatment he regards as perhaps the most significant not only the improvement in the technique of thoracic surgery but also the better understanding of what is implied by collapse therapy, involving various tactical forms of one common strategy. Sir Leonard Rogers brings his unique experience to bear on recent work on tropical diseases, and Prof. Dilling, as usual, deals with recent developments in drug therapy. The rest of the volume consists of careful abstracts arranged alphabetically according to diseases. As Prof. Bruce Perry summarizes it, "during the year no phenomenal advance has been made in any special field, but there has been steady progress on all fronts." And of that progress this volume is an admirable record.

BACTERIA IN RELATION TO MILK

Bacteria in Relation to the Milk Supply. A Practical Guide for the Commercial Bacteriologist. By C. H. Chalmers, B.Sc. 3rd edition. (Pp. 272; illustrated. 8s. 6d.) London: Edward Arnold.

The third edition of this handy little compendium of information on dairy bacteriology will be welcomed by dairy students, commercial bacteriologists, sanitary inspectors, and not a few medical officers of health. The sections on control of milk at the farm and at the creamery have been rewritten. There is a good critical review of the methods available for judging the bacteriological quality of milk, and the author has not allowed himself to be carried away by the exaggerated claims made for the resazurin test. What will prove of particular value to sanitary inspectors is the description of the technique of pasteurization—both the holding and the H.T.S.T. methods—since the practical aspect of processing is so seldom considered by dairy writers in this country. The appendix containing the formulae for a number of standard media will be found useful for reference. There are a few minor criticisms. The bacteriology is not always as good or as up-to-date as it should be. The technique of examination of water supplies is fifteen years old; the method for differentiation of coliform organisms laid down by the Ministry of Health in 1939 and used in public health laboratories with great satisfaction ever since is not even mentioned. Bacterial nomenclature is chaotic. Any system that awards different generic names to organisms as closely related as *coli* and *aerogenes* or to different members of the anaerobic spore-bearing group is surely open to condemnation. The method described for the cultural examination of milk for *Br. abortus* is not likely to be very successful. The author might also consider replacing 5% carbolic acid for the disinfection of hands by 1% chloros; he will find it equally effective and far less damaging to the skin.

MASS RADIOGRAPHY OF THE CHEST

Mass Radiography of the Chest. By Herman E. Hilleboe, M.D., and Russell H. Morgan, M.D. (Pp. 288; illustrated. $3.50 or 21s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co. 1945.

This new book adds very little to that which has already been written about this topical subject, but it has the merit that it condenses otherwise scattered information into a small, well illustrated, and excellently produced volume. Perhaps the best chapter is that devoted to the objectives of tuberculosis control; here the authors present the problem concisely and sensibly and avoid the common error of exaggerating the possibilities of mass radiography in this field. Another section, promisingly entitled "Equipment Available," shows a tantalizing profusion of *x*-ray apparatus, screens, cameras, and photoelectric timing mechanisms which are not likely to be obtainable in this country for a long time. In an interesting discussion of the physical factors affecting the choice of equipment, the authors compare the relative efficiency of various sizes of film. It appears that there is much to recommend the use of 4 x 5 in. film in preference to the 35 mm. size for small surveys. The 4 x 5 in. film has twice the resolving power of 35 mm. film, so that it gives a much better rendering of detail, and it is large enough to be viewed conveniently without any magnifying or projection device. The descriptions of technique and administration are concise and comprehensive, but the section on interpretation of films is too brief to be of much practical value. There are a number of excellent reproductions of radiographs, but too many of these are of gross abnormalities or relatively uncommon conditions; of the 47 reproductions, only one shows minimal pulmonary tuberculosis.

Notes on Books

Sir ROBERT HUTCHISON'S *Elements of Medical Treatment* (John Wright and Sons, Bristol; 10s. 6d.) is a well-established favourite which has now reached a fourth edition. As might be expected from a master both of clinical teaching and of lucid writing, this book is practical in tone and definite in its directions. A pleasing feature is the care with which the reason is stated for each ingredient in the illustrative prescriptions. While relying mainly on the drugs of established reputation, due regard is paid to the newer remedies.

The St. John Ambulance Association has published from St. John's Gate, Clerkenwell, E.C.1, a third edition of its simply written booklet *A Preliminary Course of Home Nursing* (price 1s., by post 1s. 1½d.). This was originally compiled for girls under 16; but, being based on the adult textbook of the Association, many older learners have found it a useful introduction.

Dr. ROBERT G. PATERSON has written an interesting short history of the genesis and development of the antituberculosis campaign in the U.S.A. under the title *Antecedents of the National Tuberculosis Association.* This pamphlet, with eight portraits of pioneers, is published by the Association at 25 cents from 1790, Broadway, New York 19, N.Y.

The inevitably disintegrating effect of total war on family life has led Lady PATERSON to write what she terms a challenge under the title *The Family Woman and the Feminist* (William Heinemann; 2s. 6d.), which is an ardent and sincere appeal to restore the balance in favour of home life and not to leave the responsibility for the upbringing of children entirely to the State. A useful tract for to-day.

The Board of Registration of Medical Auxiliaries (B.M.A. House, Tavistock Square, London, W.C.1) has published a fifth edition (1944) of the Chiropodists' Section of the National Register of Medical Auxiliary Services. Chiropodists whose names are included in the Register have qualified according to a standard laid down by the Board and approved by the British Medical Association. A memorandum prepared by the Chiropody Group Council on the relationship of chiropody to the health of the community, with special reference to registered medical auxiliary chiropodists, is obtainable at the price of 6d.

Preparations and Appliances

A SYSTEMIC PENICILLIN APPARATUS

Mr. F. RONALD EDWARDS, M.D., Ch.M., F.R.C.S., assistant to the Professor of Surgery, writes from the Department of Surgery, University of Liverpool:

The systemic administration of penicillin is to-day carried out by a series of 2- or 3-hourly injections or by a continuous intramuscular drip. The employment of individual injections, while of great value in conditions of emergency, is associated with an increasing degree of apprehension as the number of needle punctures rises; they may amount to 70 or more in a full course of treatment. This is particularly noticeable in children and severely toxic patients. The continuous intramuscular drip apparatuses now in use are complicated, rather easily broken, and need autoclave sterilization. Their method of working, while relatively simple to the mechanically minded, become less easily understood the more untrained the staff that is called upon to control them. The increased availability of penicillin and its probable use in the home calls for a simplified form of apparatus which functions by one simple movement requiring no mechanical knowledge and when once set up can be left for days without fear of breakdown or obstruction. With these objects in view the following apparatus has been devised. It is a return to the intermittent injection method of administration, with the maintenance of a slightly less constant blood level than that given by the intramuscular drip. There is as yet no conclusive evidence forthcoming that this variation in level has a less therapeutic effect than when the intramuscular drip is used.

The Apparatus and its Use

With this apparatus the volume of penicillin solution administered during the day is 12 c.cm. if a dose is given 3-hourly and 18 c.cm. if given 2-hourly, so that the water-logging of the site of injection is minimal. The penicillin reservoir needs recharging once a day, but the actual administration can be undertaken by untrained personnel, such as the patient's relatives.

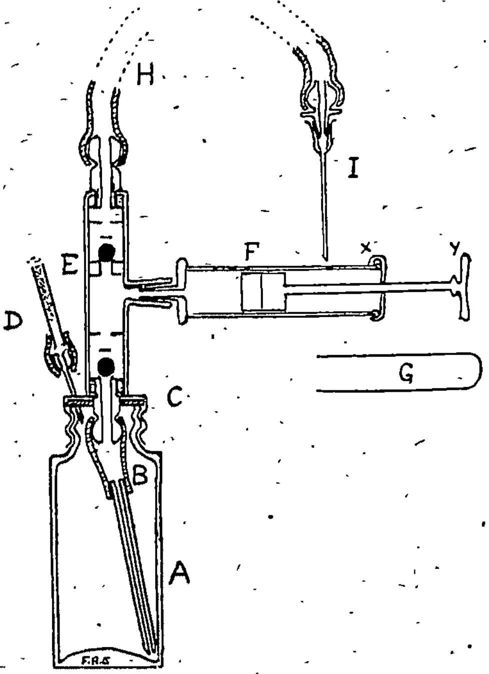

FIG. 1.—Diagrammatic representation of the apparatus. The valve mechanism is enlarged to show detail.

The apparatus is shown diagrammatically in Fig. 1. It consists of a 1-oz. wide-necked standard bottle (A), fitted with a metal cap and rubber disk (C). This metal cap is perforated to take one end of a "Riley's chest aspirator." (Riley's chest aspirator is marketed by Messrs. Alexander and Fowler, Pembroke Place, Liverpool, and is described in the *B.M.J.*, Jan. 15, 1944.) This aspirator is then fixed to the cap by unscrewing one end of the intake valve, threading on the metal cap, and replacing the unscrewed portion. A hole is cut in the rubber washer and this is replaced over the aspirator end. A hole is bored in the metal cap to take a serum needle, which acts as an air inlet into the bottle, and is maintained in position by perforation of the rubber disk. A small glass tube (D) is fixed to the outer end of the needle by a short length of rubber tubing. To the bottle end of the aspirator a piece of rubber tubing (B) and a length of wide capillary glass tubing is inserted, the whole being slightly longer than the bottle length so that the end of the capillary tubing, which is rounded off in a flame, sits in the gutter at the edge of the bottom of the bottle. To the output end of the aspirator 12 inches of rubber tubing are attached (H), and to the other end of this an adapter and a serum needle (I). To the side of the adapter a 1-c.cm. syringe is fitted (F). This syringe is fitted firmly in position by a piece of wide rubber tubing which fits over the end of the syringe for about half an inch, and is split at its opposite end so that it surrounds the body of the aspirator. The rubber tube is then pulled tight and slight tension is maintained by passing a safety-pin through the split end of the rubber tube in such a manner that the pin-legs press against the body of the aspirator (see Fig. 5). This prevents the syringe accidentally becoming detached.

The apparatus is sterilized by boiling, the piston of the syringe being removed. After sterilization the piston is reinserted and a sterile rubber glove finger (G) is threaded over the handle of the piston. This is then tied by thread on to the piston handle and the end of the barrel of the syringe at X and Y, thus keeping the inside of the syringe barrel sterile. A wisp of sterile cotton-wool is put into the glass tube D. The apparatus is then emptied of water by pumping the syringe, after which it is ready for use.

The full stroke of the piston of a 1-c.cm. syringe gives almost exactly 1.5 c.cm., and hence the concentration of the penicillin dispensed depends on this factor and the frequency with which it is proposed to administer the dose. If 100,000 units a day are to be given, then this amount is dissolved in 12 c.cm. or 18 c.cm. of saline, depending as to whether it is to be given 3-hourly or 2-hourly respectively. The requisite daily volume is dispensed in a similar bottle to A, which is found in all bacteriological laboratories. The dead space of the apparatus is approximately 3 c.cm., so that the first day's dose should be dissolved in 3 c.cm. more saline than is necessary on other days, and then on the last day the administration is continued until a syringeful of air is obtained and this is injected down the tube. If a little air goes into the muscles no harm will result.

To start the administration, bottle A is removed, and the penicillin bottle screwed in, a procedure which can be undertaken in a sterile manner quite easily. Two pumps of the syringe will fill the apparatus, and the needle is inserted into the anterior or lateral thigh muscles through a pledget of wool soaked in proflavine solution. Each dose of penicillin is given by one full stroke of the piston of the syringe, the piston being kept in the fully home position in between times.

The bottle is fixed on the inner side of the thigh with the syringe crossing the anterior aspect. It can be fixed by firm bandaging or strapping, but is most conveniently fastened to a special harness which can easily be made in the occupational therapy department or the home (Fig. 2).

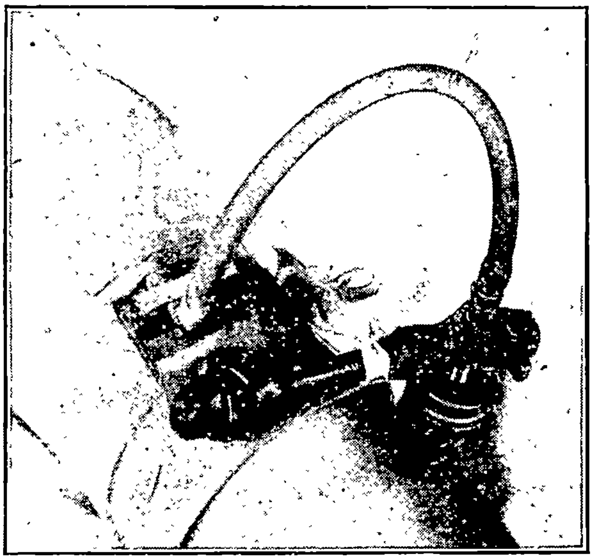

FIG. 2.—Method of fixing apparatus to the leg.

A piece of webbing 2 in. wide and 9 in. long has two tapes tied on to each end (Fig. 3). A small webbing bag is made of such a size that it fits the outside of the 1-oz. bottle, and this is stitched along one side of the webbing as shown in the diagram. Two tapes, also stitched a little further along, serve to fix the syringe barrel. A small wooden wedge is made at an angle of approximately 30° with a groove down the centre along which the tubing can lie; this maintains most comfortably and least painfully the intramuscular needle (Fig. 4). The wedge is fixed to the webbing strap in any desired position by pushing two drawing pins through from the opposite side. This type of harness is very comfortable to wear and allows considerable movement in the bed (Fig. 5), the bedclothes being kept from the leg by the use of a cage.

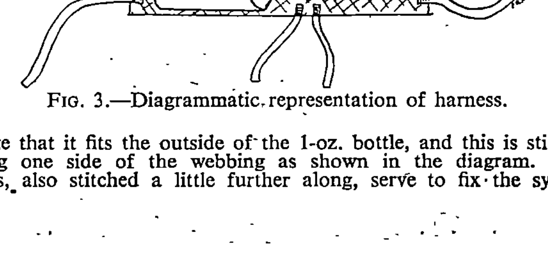

FIG. 3.—Diagrammatic representation of harness.

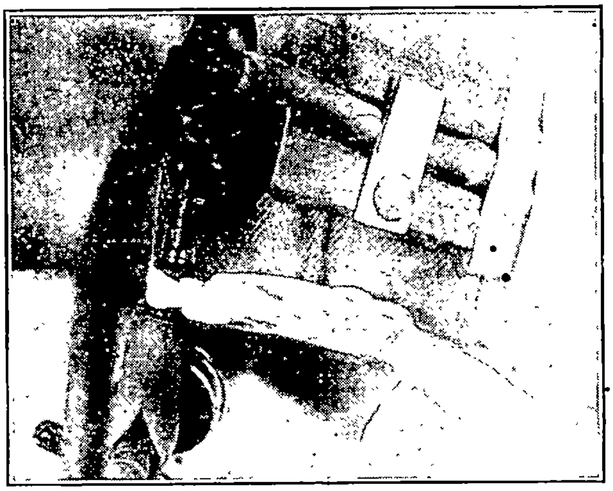

FIG. 4.—Method of fixing tubing and needle to the wedge.

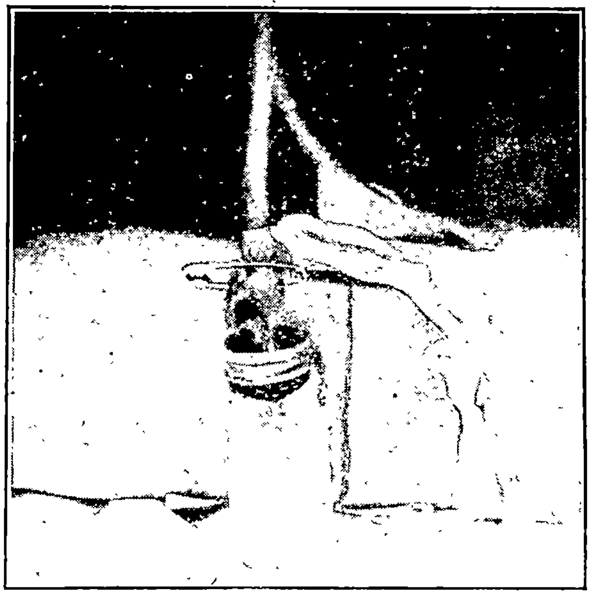

FIG. 5.—Lateral view of the apparatus *in situ*.

In use this apparatus has been found to be quite satisfactory, being preferred by the nursing staff to any other so far produced. Blocking of the needle is practically impossible as the injection is given by direct pressure, and from the patient's point of view the small amount of fluid injected causes the minimum of soreness. The valve mechanism can be cleaned by pumping water through as long as penicillin solution alone is used in it. If any serous fluid is used then it should be taken to pieces and cleaned out, because a fibrinous deposit makes it inefficient. The valve mechanism only works efficiently in the vertical and semi-vertical position, for it depends upon a ball fitting in a seating. This position is maintained by its location on the bottle.

This apparatus is made from materials in standard production, and its cost to make is approximately 25s.

I am indebted to Dr. Noel Bleasdale, registrar, Liverpool Chest Surgical Centre, Broadgreen Hospital, for suggesting modifications to the original apparatus.

J. M. Kennedy (*J. Laryngol. Otol.*, 1944, **59**, 243) records a case of laryngo-tracheal diphtheria in a pregnant woman, aged 23, which necessitated tracheotomy and was followed by delivery of a six-months foetus. She was treated with 60,000 units of antitoxin intramuscularly and 16 g. thiazamide intravenously with no complications and complete recovery.

LENINGRAD SURGEONS

BY

Prof. NIKOLAI BLINOV

The Pirogov Surgical Society of Leningrad continued its work throughout the period of the siege, although its meetings were frequently interrupted by enemy shelling; surgeons were sometimes unable to reach the meeting hall, and others had to leave in order to give first aid to the injured. Since the raising of the siege we have been able to meet regularly in accordance with old traditions.

In April, 1944, the re-election of the presidium of the society took place. Academician Peter Kupriyanov, vice-president of the Academy of Medical Sciences, was elected chairman of the presidium; the vice-chairman is Ivan Vinogradov, an old Leningrad surgeon and honoured doctor of the R.S.F.S.R., and the present author was elected secretary of the society. During 1944 the society held 19 meetings, all of which were attended by an average of 200 to 250 members.

Papers and Demonstrations

The annual Pirogov Memorial Meeting heard a paper by Col.-General Eugene Smirnov on "Pirogov and War Medicine." This dealt with the tremendous part which Pirogov played in the development of war medicine both as an organizer and as a surgeon. At the same meeting Academician Justin Janelidze read a paper on "The Free Transplantation of Skin in Russia and the Soviet Union." He gave a historical review of the subject and mentioned a number of Russian surgeons who practised free transplantation in the nineteenth century but whose names are not known to doctors in general; at this time an original method for the free transplantation of skin was proposed.

In general, questions of plastics and plastic surgery have frequently been raised at meetings of the society. Prof. Alexander Limberg spoke on "The Use in Plastics of Two Conjoined Triangles cut in the Neighbourhood of the Defect." The large number of demonstrations show that Leningrad surgeons are much interested in the technique of covering large skin defects. The methods used are the conjoined triangles (demonstrated by Xenia Stroikova and Natalia Dembo), the strip method, and others. Maria Arkhangelskaya-Levina demonstrated her own method: she removes the fringes of the wound as far as the fascia and places her transplant on the separated strips; this enables her to draw the strips together and cover the defect. All these demonstrations gave rise to lengthy discussions, during which many surgeons related their experiences in this field.

The treatment of defects in other parts of the body was also dealt with at the society's meetings. Emma Alexandrova, from Prof. Limberg's clinic, demonstrated five cases of restored lower lips and chins after gunshot wounds had been treated, and several cases of free osteoplasties for the treatment of defects and slowly consolidating gunshot fractures of the lower jaw.

Some other demonstrations were: two cases of the complete consolidation of the clavicle without the development of osteomyelitis, when the bone had a defect 6 to 7 cm. in length as the result of a gunshot wound (Nikolai Blinov); patients with false articulations cured surgically (Prof. Grigory Epstein). Prof. Epstein also in a paper on "Operative Treatment of 225 Cases of False Articulation in Peace and Wartime" showed preference for osteoplastic methods and objected to the fastening of the bones with metal fasteners. The technique of amputations after gunshot wounds in limbs and methods of post-operative treatment to ensure the formation of a firm stump were dealt with by Prof. Alexander Nadein. He proposed the use of plaster bandages on the stump after the operation. Prof. Vladimir Weinstein read a paper on plastic covering of the knee-joint with the aid of the patella. Thus it can be seen that Leningrad surgeons show considerable interest in questions of plastic surgery.

Until quite recently a large number of cases were demonstrated in which foreign bodies had been removed from the organs of the thorax; this year, however, only special cases were demonstrated—for example, removal of shell splinters from the right ventricle, removal of a bullet from the heart, removal of a foreign body from the lungs, and a case in which a metallic foreign body had passed through the heart.

Several papers were read on the treatment of gunshot wounds and subsequent osteomyelitis: wound of the hip-joint (Grigory Gomziakov), wound of the proximal part of the thigh (Nikolai Tseringer), and gunshot osteomyelitis of the pelvis (Prof. Y. Ryvlin). The papers were based on the rich material of the Leningrad military hospitals and led to very animated discussions, which enabled the society to define its attitude towards these injuries and determine the indications for resection of the hip-joint and the pelvis. In a paper on "Iodoform–Vaseline Tampons as a Method of Closing Bone Fissures," read by Prof. Peter Kornev, 650 cases were analysed; the paper illustrated the advantages of this treatment, which were confirmed by other surgeons in the discussion that followed.

Cases of good primary and later treatment of gunshot wounds were demonstrated and showed the high degree of skill attained by Leningrad surgeons. The papers and demonstrations proved that surgery can give back their lives to people who had lost all hope.

INTER-ALLIED CONFERENCES ON WAR MEDICINE

The long series of inter-Allied conferences on war medicine, held in private under the chairmanship of Sir Henry Tidy at the Royal Society of Medicine, came to an end on July 9, and to commemorate it there was a farewell dinner that evening at 1, Wimpole Street. This was an informal gathering and most enjoyable. The only neighbouring Ally unrepresented was France, because Col. Vignol and his colleagues had had to return to Paris on duty. The guests were welcomed on behalf of the R.S.M. by its President, Surg. Rear-Admiral G. Gordon-Taylor, with Mr. J. B. Hunter, hon. treasurer, Mr. R. H. O. B. Robinson, hon. secretary, and Mr. Geoffrey R. Edwards, the secretary. Besides the representatives listed below the dinner was attended by Sir Alfred Webb-Johnson, P.R.C.S., Mr. Eardley Holland, P.R.C.O.G., and Mr. H. S. Souttar, President of the B.M.A.; Lord Horder, Sir Ernest Rock Carling, Sir Francis Fraser (Director-General E.M.S.), Dr. Geoffrey Evans, Dr. D. P. O'Brien of the Rockefeller Foundation; and the editors of the *Lancet* and the *British Medical Journal*. Sir Henry Tidy took the chair and recalled the many valuable discussions that had taken place at 1, Wimpole Street on the application of medicine to the organization of medical service for war, mentioning dryly the acute differences of opinion that arose and the lessons that might be drawn from them. The meetings, he said, had fulfilled their object. He paid tribute to Col. Gallemaerts for his initiative in the matter and to Brig.-Gen. Elliott Cutler for his later services; also to Mr. Edwards for organizing the conferences, to the R.S.M. for its hospitality, and to the medical heads of the Services for arranging the discussions. Surg. Rear-Admiral Gordon-Taylor spoke eloquently of the medical services of the Allies and of the friendships forged by these meetings. Group Capt. Fiumel briefly acknowledged the toast of the guests, Brig.-Gen. Cutler (as Major-Gen. Hawley's deputy) distributed a double handful of bouquets to various inter-Allied colleagues, and Col. Gallemaerts also spoke in reply.

Representatives at the Farewell Dinner

Canada.—Major-Gen. R. M. Luton, D.G.M.S. Brig. J. H. Palmer.

Australia.—Brig. W. A. Railes.

New Zealand.—Brig. J. M. Twhigg.

Great Britain.—Surg. Vice-Admiral Sir Sheldon Dudley, D.G.M.S., R.N. Lieut.-Gen. Sir Alexander Hood, D.G.A.M.S. Air Marshal Sir Harold Whittingham, D.G.M.S., R.A.F. Lieut.-Gen. Sir Ernest Bradfield, India Office. Major-Gen. A. G. Biggam. Major-Gen. D. C. Monro. Brig. J. M. Macfie. Col. D. A. O. Wilson. Air Vice-Marshal C. P. Symonds. Brig. H. L. Marriott.

Belgium.—Col. Victor Gallemaerts.

Czechoslovakia.—Lieut.-Col. Mahler.

Norway.—Surg. Cmdr. G. Finson.

Holland.—Major W. Van der Sluys. Surg. Capt. V. M. J. Kettlitz.

Poland.—Group Capt. A. Fiumel. Surg. Cmdr. B. Danielowicz.

U.S.A.—Brig.-Gen. Elliott C. Cutler. Capt. C. J. Brown (U.S.N.). Col. W. S. Middleton. Col. Ellis. Col. Harry G. Armstrong. Col. Lloyd Thompson.

J. H. Press, E. L. Shlevin, and A. P. Losen (*Ann. intern. Med.*, 1945, **22,** 546) record their observations on a series of 96 cases of sporadic infectious mononucleosis seen at the Jewish Hospital, Brooklyn, over a ten-year period. The diagnosis of infectious mononucleosis is in order in the presence of a suspected clinical picture when the blood findings are positive. A positive Paul-Bunnell test is strongly indicative of the disease, but its absence does not exclude the diagnosis.

LONDON

SATURDAY JULY 21 1945

HAEMOGLOBIN LEVELS IN THE FOURTH YEAR OF WAR

At the request of the Ministry of Health the Medical Research Council undertook to obtain evidence as to the nutritional state of the people of Great Britain in the fourth year of war. The Council appointed a special committee to consider the problem, recognizing from the outset that the nutritional state of an individual or a community depends not only on the availability of foodstuffs but also on hygienic, sociological, and psychological factors. Although it is clear that no single examination can provide a complete measure of nutritional state, it is known that long-continued deficiency in iron will affect the haemoglobin level and that long-continued deficiency in protein will tend to affect all the proteins of the blood. The committee therefore decided to institute a co-ordinated series of investigations of haemoglobin and protein levels in the blood of representative samples of the population. The results which have now been published[1] should give legislators, physicians, and workers in the social sciences much to consider, and it is to be hoped will stimulate them to constructive action.

Haemoglobin estimations were made on 13,000 adults and 3,000 children in various social and occupational groups by the Haldane-Gowers technique, for reasons discussed at length in the report. These data have been subjected to statistical analysis, and an attempt has been made to compare the results (*a*) with levels previously regarded as normal, and (*b*) with levels obtained in similar surveys made both before the present war and since the onset of rationing in 1940. Only results obtained by the same method as that used in the present survey were employed in this comparison, but in many instances the instruments were not available for standardization, and previous workers had often failed to make it clear that in selecting their groups they had appreciated the many physiological factors which may affect haemoglobin levels. Their results are therefore not always easy to interpret. For these reasons the committee feels, on the evidence available, that it is unjustifiable to accept a normal mean for any group in the community except men. Taking all the facts into account, it concludes there is no greater degree of anaemia present in the survey groups than there was in the limited pre-war samples and in groups studied in the first years of the war, and that in certain groups, notably pregnant women, there is probably less. Though the results suggest, then, that in the group studies the incidence of anaemia has not increased, thus agreeing with other published results for 1943 and 1944, they also indicate that there is still an undue amount of preventable anaemia which may be due to lack of haemopoietic factors, especially iron in the diet. This anaemia is found particularly in infants and young children, pregnant women, housewives, and certain occupational groups, especially a group of factory workers and agricultural workers. Serum protein estimations were made on 353 blood donors, who may be taken as a fair random sample of the population according to other evidence contained in the report, and on 100 Canadian soldiers taking the British Home Service ration. The mean level for the 353 English donors was significantly lower than that of the Canadian soldiers. It is tentatively suggested that the difference observed between the two groups is dependent upon the difference in animal-protein intake in the diets.

In discussing these results the committee accepts the possibility that the higher iron content of national bread may be responsible for the rise in haemoglobin observed, but states that the available evidence makes this conclusion indefinite. Other factors, such as the animal-protein level of the diet, may be of equal importance, but it is suggested that any future proposal to change the bread supplied to the community should take cognizance of its possible effect on haemopoiesis. The committee concludes: "An effort should be made to reduce the considerable proportion of low levels of haemoglobin which some groups still reveal—e.g., young children, pregnant women, and persons at the lower economic level." This report illustrates in a striking way, quite apart from the interest of its immediate findings, the need for the closest future collaboration of medicine with the social sciences if the solution of many problems essential to the well-being of the community is to be found. Why, for instance, is the haemoglobin level of agricultural workers so much lower than that of London policemen and higher-grade civil servants? Why were low figures found in a group of textile workers? The answer must surely lie in social and economic factors, and for their proper elucidation medicine must look for help to the social scientists. What is true of nutrition is also true of other medical problems, such as sickness absenteeism in industry.

THE VESICO-VAGINAL FISTULA

In recent months a number of publications have appeared concerning the treatment of vesico-vaginal fistulae. This injury is now rarely seen in this country, but in parts of India, Africa, and other lands where midwifery services are undeveloped it is still an all-too-common sequel of difficult labour. Sir J. Y. Simpson spoke of it as "the most depressing and deplorable of all infirmities to which woman is liable, a condition looked upon as beyond all relief and help." Long years ago Marion Sims and other workers broke this conception, but in spite of their work the condition to this day retains more than a little of its sinister reputation.

There is no doubt that the surgical closure of a fistula can on occasions be a "tricky business"; nevertheless, many surgeons have considerable success to their credit. Mahfouz Pacha,[1] of Cairo, writing with experience of more than 400 cases, reports that, of his last 100, 95% were cured by vaginal operation. Schmitz,[2] Miller,[3] and Phaneuf[4] in the U.S.A. have all reported a high proportion of successes, though their individual series have been much smaller. Recently Benion Thomas,[5] working in India, has described 40 cases of fistula; 28 of them were treated by vaginal operation and 25 cured. Thompson[6] also has reported successful closure by vaginal operation in a high proportion of difficult cases admitted to a mission hospital in India. At a recent meeting at the Royal Society of Medicine Chassar Moir[7] presented his results in cases collected from different parts of this country, in many of which there had been previous multiple operations with consequent extensive vaginal scarring. In each of 24 cases the fistula was closed by vaginal operation, and usually at the first attempt. The results of these and other workers leave little doubt that the great majority of vesico-vaginal fistulae are capable of repair by simple surgical methods and by direct approach from the vagina.

[1] *J. Obstet. Gynaec. Brit. Emp.*, 1938, 45, 405.

It must, however, be conceded that sometimes a fistula is found in so difficult a situation or surrounded by so much scar tissue that further attempts at local closure must be abandoned. In these circumstances the operation of transplantation of the ureters—first performed by Stiles, of Edinburgh, on infants suffering from ectopia vesicae—must be considered. It is surprising how little this drastic alteration of human physiology does in fact upset the patient: the person concerned is usually able to lead a normal life with full control of the rectum—now changed to cloaca. Grey Turner[8] has recorded the late history of many such patients, most of whom have continued to enjoy excellent health for years. In our present issue Douglas reports 11 such operations for irreparable vesico-vaginal fistula, and comments on the gratitude of the patients for the relief they have obtained. His notes on operative technique will be read with interest by those who may have to perform the operation.

But there is another side to the picture. The mortality of ureterocolostomy is by no means negligible. Murray and Ahmed,[9] writing with experience in India, report that, of 65 patients, 14 (21.5%) died after the operation. Roberts,[10] working in Nyasaland, performed the operation in 90 cases with an immediate mortality of 12.2%, though in 41 cases in which the Coffey No. 1 operation was performed in two stages there was only one death. Douglas, too, in his present series reports two deaths from peritonitis in eleven cases. Those statistics refer to immediate deaths only. A few later fatalities from pyelo-nephritis are inevitable, though not many surgeons in this country would go so far as Mahfouz Pacha when he says " few patients survive the operation more than three years." Possibly the prevalence of bilharzial and other infection adds to the danger of the operation in certain tropical or subtropical countries. It is clear, therefore, that great judgment must be exercised in selecting cases for the formidable operation of ureterocolostomy. When a fistula is truly irreparable it is, however, the patient's only hope. By it alone can prospect be given of something happier than a life of semi-seclusion, of physical discomfort, and of constant embarrassment in the presence of strangers, that is otherwise the woman's lot.

For most surgeons the vesico-vaginal fistula is so rare an encounter that experience in the technique of plastic repair of the bladder and vagina is hard to gain. Yet, perhaps more than in any other comparable operation, it is of paramount importance that the patient should be treated on sound lines from the first. Schmitz has expressed himself forcefully in this matter:

> " One of the greatest causes of failure in fistula operations must be attributed to a lack of understanding of the problem involved by the person who first attempts to close the opening. The percentage of bad results mounts rapidly after each attempted closure. Undue haste in operating and lack of willingness to work out slowly and painstakingly each bit of tissue needed contributes to failure. . . . The time to close the fistula is at the first sitting, and all vanity and professional squeamishness should be set aside to the end that a case of this kind may get into the proper hands from the very beginning and not after an unsuccessful attempt to close has seriously jeopardized the patient's chances of prompt and complete recovery."

These words must be taken to heart by anyone in general or in special practice who may be called upon to give advice to a patient unfortunate enough to suffer from this distressing condition.

THE BRITISH COUNCIL'S MEDICAL DEPARTMENT

The British Council, which now celebrates its tenth anniversary, has steadily built up a wide range of services in the medical field. The work of the Medical Department is directed to promoting knowledge over-seas of medical science in Britain, and facilitating contact between the medical professions of this and other countries. It issues the *British Medical Bulletin* at approximately monthly intervals. This contains original articles, abstracts, books reviews, and lists of the contents of current British medical and cognate journals. There are editions in English, French, Spanish, Portuguese, and Turkish, but circulation has hitherto been restricted to medical editors, teachers, investigators, and libraries. In 1944 arrangements were made for a limited number of copies to be available by subscription in this country, and this method of distribution is being developed in several places abroad. The Council acted on the suggestion of a distinguished Swedish professor of medicine that the English edition should be reprinted in Stockholm. The Turkish edition is produced from the Council office at Ankara, and the Turkish Ministry of Health has helped in its distribution.

Requests for copies of papers (reprints or photostats), bibliographies, and general information on a wide variety of medical subjects are received in increasing volume, and now form an important part of the work. Exchanges between British and foreign medical journals are arranged, and British medical books and journals are supplied to oversea medical libraries. Arising out of these services many requests come for small supplies of new drugs for research purposes, and for new or improved types of medical instruments and apparatus of British manufacture. Wherever possible the Department obtains samples of drugs, sometimes not yet commercially available, for interested research workers, and may even act as intermediary for the purchase of equipment and apparatus by oversea medical men and institutes. It also acts as an agent for the supply to foreign laboratories of standard bacterial cultures, sera, etc. A start has been made on a programme of medical films, with commentaries in several languages, intended primarily for oversea medical audiences. Two—"Surgery in Chest Disease" and "Accident Service"—have been widely shown in this country also. A small committee views existing medical films, most of which are amateur 16 mm. productions made by surgeons or others interested in the application of cinematography to medical teaching.

Medical visitors come sometimes as the guests of the Council, sometimes at their own expense, and programmes are arranged for them in consultation with suitable experts and professional organizations. Recently there have been such visits by a professor of public health and a surgeon from Portugal, three Turkish members of a medical mission appointed by the Turkish Ministry of Health, and medical missions from France and Belgium. Medical graduates are now in this country as British Council scholars from France, Belgium, Turkey, Portugal, and Argentina. Study-programmes are arranged for them, and contact is maintained with them during their stay. Visits abroad by distinguished medical men are sponsored by the Council. These involve the delivery of lectures and informal contacts with representatives of the medical profession abroad. In 1943 the Council and the Medical Research Council jointly sponsored a British surgical mission to the U.S.S.R., which was later extended to become an Anglo-American-Canadian mission.

The Medical Department, under Dr. N. Howard Jones, is a unit in the Science Department, advised by a science committee whose chairman is Sir Henry Dale. Sir Edward Mellanby is chairman of the medical panel. Individual experts in various subjects are often consulted—whether on a request for information, the making of a film, matters in connexion with the *Bulletin*, or a programme for a medical visitor—and their willingness in most cases to give of their wealth of special knowledge has been most encouraging. Such outside collaboration is essential to the work of the Council, whose function is not so much to provide technical information as to act as a channel through which the knowledge and opinions of experts can be obtained

FOLIC ACID

Folic acid, so called because it occurs in green leaves, is one of the most recently discovered members of the vitamin B complex. It was originally defined as the active principle required for the growth of the micro-organism *Str. lactis R.* under specified conditions.[1] The substance has not yet been identified chemically, though its empirical formula is known and much of its chemistry has been worked out.[2] It is acidic in nature, contains nitrogen, and has a molecular weight of about 500. It has been suggested that folic acid is chemically related to xanthopterin, the yellow pigment in butterfly wings, because the absorption spectra of the two compounds are similar, and xanthopterin incubated with liver tissue produces folic acid. More recent work, however, identifies it with vitamin B , also known as the chick anti-anaemic factor, which is present in liver and yeast. Until pure folic acid becomes generally available much of the work already done on it will need confirmation, as hitherto this has been done mostly with concentrates containing the substance.

Folic acid has in minute quantities a powerful growth-stimulating action on normal cells, and is a growth factor for rats, dogs, pigs, and certain bacteria. It inhibits tumour growth.[3] Recently it has been reported[4] that complete regression of breast cancer in mice occurred in 43% of the affected animals treated daily with 5 μg. of folic acid. No tumours regressed among control mice not treated with folic acid. Certain animals, including the rat, can synthesize folic acid in the intestine; this is probably effected by the agency of the coliform bacteria of the gut, for it is inhibited by the bacteriostatic action of such sulphonamides as succinylsulphathiazole and sulphaguanidine.[5] There is some evidence that folic acid is associated with haemopoiesis. The anti-anaemia properties of liver concentrates for the chick have been recognized for some years, and the active principle in liver has now been identified with folic acid.[6] It has been shown that the granulocytopenia, leucopenia, and anaemia produced in rats receiving sulphonamides in purified diets can be prevented by administering folic acid, the level of which falls considerably in the liver when these drugs are given.[7] Folic acid probably acts by stimulating the bone marrow rather than by directly inhibiting the sulphonamides, as it can prevent and correct the granulocytopenia sometimes observed in rats fed on purified diets without the sulphonamides.[8] It has been suggested that folic acid and biotin, another member of the vitamin B complex, are essential for making use of pantothenic acid and vitamin K. It is not known whether folic acid is essential for human nutrition. So far not enough pure folic acid has been available to test its curative effect in any of the nutritional syndromes seen in man. The human excretion of folic acid is very low—about 10 μg. daily—compared with the average daily intake of 1.4 mg. The significance of this is quite unknown.

INSULIN FOR DELIRIUM TREMENS

Delirium tremens is a serious illness. According to Piker and Cohn[9] its mortality when treated by the standard methods is about 5%. Once the patient can be got to sleep for 6 to 7 hours he is usually well on the way to recovery. He generally receives, therefore, not only plentiful fluids but also fairly heavy sedation by such relatively safe drugs as paraldehyde. Unfortunately, however, alcoholics are more than usually tolerant of this drug, and it may produce not the desired sleep but only increasing restlessness. The clinical state of the patient can be mild or very severe; on an average the length of stay in hospital has to be about five days. Considerable improvement on these figures has been claimed by several authors[10-13] who employed insulin therapy. The injection of insulin may be followed almost immediately by giving glucose; but according to Tillim the best results are obtained when the patient does not receive it until after 2½ hours, which he has spent in a soporose state, perspiring freely. The dose of insulin is determined empirically, but will as a rule be from 40 to 80 units. If the initial dose is insufficient to produce a soporose state in an hour a second injection can then be given intravenously. If the patient shows signs of going too deep the insulin may be "fractionally" neutralized by 5 to 10 grammes of glucose intravenously. Throughout the treatment he should be supplied with plenty of water to drink, and after it a large meal, for which he will have an excellent appetite. As a result of this he becomes much more composed, and at night will sleep with only a small dose of nembutal or other suitable hypnotic. One to four such treatments, of which two may be given in twenty-four hours, usually suffice for complete recovery. The average stay in hospital is halved.

Tillim has also reported good results with this method in the treatment of opiate-withdrawal states. It is interesting that insulin was first used in the treatment of withdrawal symptoms in morphine addiction by Sakel about fifteen years ago, and his observations led him to try insulin in schizophrenia, where it is pushed to the point of producing coma. So-called modified insulin treatment (Sargant and Craske,[14] Sands[15]) is in practice the same as the method employed by Tillim, and no coma but only sopor is produced. It has proved very successful in this war in treating neurotic reactions among battle casualties, especially those that occur in a setting of physical exhaustion. The biochemical bodily changes induced by hypoglycaemia seem to be of benefit, therefore, in clinically very different states. It is time we knew more of their nature and by what paths they bring about their results.

LUMBAR GANGLIONECTOMY

After the long period during which we have been unable to keep in touch with the activities of French surgeons it is good to read a communication made by Leriche to the Académie de Chirurgie[16] upon the results of 800 lumbar ganglionectomies, and to find that the ardour and enthusiasm which we have come to associate with his work and writings are apparently unabated. The largest and most interesting groups are those in which the operation was performed for obliterative arteritis, arterial hypertension, megacolon, and the sequelae of phlebitis. Unfortunately all forms of arteritis are grouped together, and the statement is made that, provided the operation is performed early enough in the evolution of the disease, success will be achieved. In the earliest stage, when signs of ischaemia appear only on exertion, results are good; later, when there are symptoms at rest, only half the cases respond to ganglionectomy; and in the final stage of trophic ulceration and gangrene it is too late to operate. Some clinicians who take a special interest in vascular disease would hesitate to accept Leriche's rather dogmatic statements about this grouping, and from other remarks in this communication one can tell that he is not perfectly happy about it even in his own mind. He alludes to the causes of the arteritis and to the level of the block as matters of some importance, without making it clear that they may in fact be preeminent. Adrenalectomy, in his belief, is the proper treatment for thrombo-angiitis obliterans.

For hypertension Leriche advises on the right side section of all the splanchnic nerves with the last two thoracic and the upper two lumbar ganglia; and some weeks later the same operation on the sympathetic trunk and splanchnic nerves of the left side, plus adrenalectomy. For the aftereffects of venous thrombosis ganglionectomy may be successful in relieving pain and diminishing or even abolishing oedema. With ulceration there is less hope of success, and once again the earlier the operation is done the better. When it fails—and it seems to be impossible to predict its result with confidence—extensive resection of the thrombosed vein may yet give relief. For megacolon bilateral lumbar ganglionectomy with section of the splanchnic nerves on one, usually the right, side is considered the operation of choice. A plea is made for further study of the anatomy and physiology of the sympathetic system so that more limited operations may be effective. Leriche criticizes the modern tendency to carry out more and more extensive resections in order to ensure the destruction of all the sympathetic pathways along which impulses could possibly travel; for, although these operations carry a small mortality rate, the needless sacrifice of nerves which must be of physiological importance should be avoided.

In this brief summary of the work of 20 years it has obviously been impossible to give proper consideration to all the observations and impressions which have gone to make up the experience amassed in that time by Leriche and his collaborators, and we look forward to a full-length presentation of all the clinical details in the near future.

A GREAT ABDOMINAL SURGEON

The centenary of the birth of Lawson Tait was celebrated on June 30 at Birmingham by the University of Birmingham, the Midland Medical Society, and the Birmingham Women's Hospital. Prof. Leonard Gamgee gave a commemorative oration, with particular reference to Tait's outstanding work in Birmingham, where he settled in 1870 and was instrumental in founding the Women's Hospital; there he became an increasingly brilliant operator and achieved the sequence of advances in abdominal surgery which have made him famous. Robert Lawson Tait was born in Edinburgh of Scottish parentage on May 1, 1845, and entered as a student of medicine at the University; in 1866 he was admitted a licentiate of the Edinburgh Royal Colleges. He assisted Sir James Young Simpson for a time and was greatly influenced by the example of James Syme, whose habits in surgical work were in contrast with the methods and results of most of his contemporaries. In Birmingham, as Sir D'Arcy Power wrote in the *Dictionary of National Biography*, Tait soon made a name for himself as a bold surgeon, an aggressive enemy, and an original thinker. He became F.R.C.S.Ed. in 1870 and F.R.C.S.Eng. in 1871. Two years later he was awarded the Hastings gold medal of the British Medical Association for his essay on diseases of the ovaries. It was in 1873, too, that Tait performed his first hysterectomy for myoma of the uterus. In 1876 he removed a haematosalpinx, and thus made the profession familiar with the pathology of this condition. In 1879 he did his first cholecystotomy, which marked the beginning of the rational surgery of the gall tract. In 1883 he first performed the operation for ruptured tubal pregnancy, and saved the patient. Lawson Tait took a large part in organizing the Birmingham Medical Institute and was one of the founders of the British Gynaecological Society. By 1878 he had begun to express doubts as to the value of the Listerian precautions then adopted by most operating surgeons, and thus became a leader in the school of aseptic as opposed to antiseptic surgery. In the B.M.A. Tait was a member of Council, president of the Birmingham Branch and also of the Worcestershire and Hereford Branch, and in 1890 gave the Address in Surgery at the Annual Meeting in Birmingham. The Medical Defence Union owed much to him. He died after a long illness on June 13, 1899. As a surgeon (to quote again from D'Arcy Power) he simplified and perfected the technique, and greatly enlarged the scope, of abdominal surgery. Consummate operative skill, coupled with his power of generalization, enabled him to extend the range of uterine surgery and to apply its principles to other abdominal organs.

As part of the memorial ceremony at Birmingham the honorary degree of LL.D. was conferred by the University on Major-Gen. P. R. Hawley, chief surgeon to the American Forces in the European theatre of war, and on Mr. Eardley Holland, P.R.C.O.G.

We are again asked by the Central Medical War Committee to draw the attention of readers to the urgent need for medical officers to serve with a large company operating in the Middle East. An advertisement inviting applications for these posts appears in our advertising columns this week. The filling of the posts is important and urgent, and the Central Medical War Committee will most carefully consider the possibility of any selected applicants within its jurisdiction being allowed to accept them.

TEACHING AND PRACTICE OF CHEMICAL PATHOLOGY

A MEMORANDUM BY THE CHEMICAL PATHOLOGISTS OF THE LONDON TEACHING HOSPITALS

The role of chemical pathology in the study of disease and in the practice of medicine is of great importance, yet its position in the curriculum and in the final examination has not received its proper recognition. The Committee of the Chemical Pathologists of the London Teaching Hospitals has met on several occasions and has prepared the following memorandum in order that the present unsatisfactory position may receive attention.

The Goodenough Report

With certain qualifications we agree with the following recommendations of the Goodenough report.

(*a*) Chemical pathology should form a separate department in the division of pathology and should be under the direction of a professor, reader, or senior lecturer. To this we would add that the chemical pathologist should be a full member of the medical committee of his hospital.

(*b*) Proper assistance and equipment should be provided. The staff proposed in the Goodenough report of one departmental head, one senior lecturer, one resident assistant, two demonstrators (one of whom is part time), six technicians, and one secretary-typist for a thousand-bed hospital is based on the assumption that much of the routine chemical work will be done in the department of clinical pathology. If our alternative recommendation (see below) on this point be accepted it would necessitate some extra staff in the department of chemical pathology, which would best be provided by the appointment of an additional science graduate, a type of worker whom we consider specially desirable in this department. An extra junior technician might also be required. If many tests are to be done on patients in the laboratory a nurse will be needed. Bench space should also be available for research scholars working on special problems.

The selection of suitable technicians for the department of chemical pathology is a difficult problem, but we would recommend that whenever possible they should be of an educational standard such that they could read for a scientific qualification, and that they should be given every encouragement to do so.

(*c*) Undergraduate teaching in chemical pathology should be given in the form of a short introductory course at the commencement of the clinical period, with other lectures and lecture-demonstrations spread over the remaining clinical years.

(*d*) Proposals for the training of pathologists allow a period of three to four years, which are to be divided between the four departments. A further period in the special department is required by anyone desiring to specialize in one branch. This scheme is well designed to create pathologists with experience in all branches to take complete charge of smaller laboratories. It is doubtful whether such an arrangement is equally suitable for those who intend to specialize in chemical pathology, and we would emphasize the importance of making the training as elastic as possible, as in fact has been suggested in the Goodenough report (chapter 17, para. 34, p. 218).

There is, however, one main proposal in the Goodenough report with which we cannot agree—namely, that which allots the "routine" chemical work to the clinical pathologist. In our opinion this arrangement would have the following disadvantages.

(i) The chemical pathologist would be largely cut off from the clinical material which should form the principal source of his inspiration, and his teaching of the basic principles and routine methods would tend to lose contact with current practice. Thus if, for example, no routine blood urea estimations were performed in his department, both the technique and the interpretation of this test would eventually become something remote from his personal experience. (ii) The standard of chemical work would be lower. (iii) The tendency to specialization in pathology, recognized in the report, is inevitable, and it is a retrograde step to aim at a type of pathologist who has, by definition, avoided specialization. This may be necessary in the smaller hospitals, but it is not an ideal solution for the large teaching hospital. (iv) In a hospital of a thousand beds the amount of routine work in haematology and bacteriology will be so large that the addition of routine chemical tests would be an excessive burden on the department of clinical pathology. (v) The liaison between pathologist and clinicians, on which great emphasis is rightly laid, will finally depend more upon the growth of a generation of clinicians who are interested in pathology than upon the creation of a non-specialized pathologist. We are therefore strongly in favour of some modification of this proposal such as one of the alternatives discussed in the next paragraph.

Relation of the Routine Laboratory to the Main Pathology Departments

While wide variations in the pattern of organization of the pathology division in teaching hospitals may be desirable or necessary, the geographical position of the laboratories is an important factor in most cases. So far as chemical pathology is concerned two principal alternatives are in operation at this time:

(*a*) The chemical pathology laboratories are all situated in one place, which may be in the hospital, medical school, or special institute of pathology or biochemistry. In this case we suggest some arrangement such as that mentioned in the Goodenough report (chapter 8, para. 22, p. 143), whereby specimens and requests arrive at a central sorting office with subsequent dispatch to the appropriate department. In such circumstances the specimens are often collected by students or house officers, who are responsible for their proper delivery. It is important that adequate accommodation should be provided in the laboratory for certain special tests on in-patients and on out-patients which cannot be done satisfactorily in the wards—for example, basal metabolism estimations, and other procedures such as sugar-tolerance tests, urea-clearance tests, etc., are better carried out in the laboratory. This requires the provision of several suitably equipped patients' rooms, which have proved of great value in at least two hospitals where this arrangement is in use. It also requires the help of at least one nurse.

(*b*) In certain cases another laboratory, suitable for clinical pathology, is situated in the hospital, the main laboratories being elsewhere. Many routine chemical estimations are then carried out in this clinical laboratory—an arrangement which is convenient for patients and clinicians but which makes adequate supervision of the work more difficult. We suggest that such hospital laboratories should be organized by the heads of the departments of bacteriology, clinical pathology, and chemical pathology, the director of the division of pathology being the responsible administrative officer. The chemical pathologist should, however, always be responsible for work of a chemical nature which might well be undertaken by a specially appointed senior member of his staff.

Liaison between Chemical Pathology and Pre-clinical Biochemistry

As will be seen in our recommendations on the curriculum, we recommend that detailed practical instruction should not be given during the years of clinical study, so that it is desirable that pre-clinical instruction should include methods actually used in chemical pathology. For this reason the person responsible for the department of chemical pathology in a medical school should attend staff meetings of the pre-clinical biochemical department of that school, where this exists. Where the school does not possess a pre-clinical department other means should be adopted of effecting a close liaison between the department of chemical pathology and the biochemical department in which the students have received their pre-clinical instruction. It is important that there be continuity in the teaching of chemistry and biochemistry throughout the students' career.

Curriculum

We propose the following curriculum, which is based on the assumption that a total of 24 hours' instruction during the clinical period should be adequate.

(i) An introductory course of six hourly periods, early in the first clinical year, dealing with the general principles and including instruction on the collection of specimens and on urine testing. In hospitals where all students serve as clerks in pathology and are personally instructed in these matters, this course could be omitted.

(ii) A general course of 18 hourly periods during the second and third clinical years, covering the whole subject of the application of chemical methods to clinical problems.

(iii) A limited number of lectures on special aspects and recent advances given during the pre-registration year.

It is recommended that, while detailed practical instruction should not be emphasized during the years of clinical study, facilities should be provided for students to acquire some practical experience.

Examinations

An analysis of some questions set in the final pathology papers during a period of more than 10 years gives the following results:

Examination	No. of Questions Analysed	No. Entirely Chemical	No. Partly Chemical
M.B., B.S.	167	8	24
M.R.C.S., L.R.C.P.	281	25	16

In the M.B., B.S. examination a complete absence of entirely chemical questions was noted over a particular 4-year period. In our opinion this position as a whole is discouraging to the teachers and is not in line with the importance of biochemistry in current medical practice. We therefore recommend that in every examination of pathology chemical pathology should receive representation equal to that accorded to the other three branches, and that the chemical questions should be set by a chemical pathologist appointed to the board of examiners for that purpose. If the pathology examinations become internal, as recommended in the Goodenough report, there would be no difficulty in arranging for the chemical question to be marked by the chemical pathologist, who should also take part in any practical and viva voce examinations.

Summary

The recommendation of the Goodenough report whereby the clinical pathologist undertakes the routine chemical work in teaching hospitals is criticized and some alternative proposals are offered.

A closer liaison between the pre-clinical biochemical and chemical pathology departments of medical schools is advised.

An outline of a curriculum has been prepared.

We recommend that in every examination of pathology chemical pathology should receive representation equal to that accorded to the other three branches.

ROYAL COLLEGE OF SURGEONS MUSEUM

GIFT FROM THE WELLCOME TRUST

The letter printed below, offering £80,000 towards the cost of extending the museum accommodation of the Royal College of Surgeons of England, has been sent to the President of the College by Sir Henry Dale, P.R.S., chairman of the Wellcome Trustees.

Dear President,

When you were good enough to put before the Wellcome Trustees the plans for restoration and rebuilding which had been made for the Royal College of Surgeons, we explained to you that the particular item of the activities of the College which, under the terms of our Trust, we were entitled to consider as suitable for a grant in aid of the proposed rebuilding and extension, was the great service which the Royal College has so long rendered to surgery, and to a much wider range of medical and scientific knowledge, by the maintenance of its historic and world-famous museums of human and comparative anatomy and pathology. As we also then informed you, one of the clauses of the will of the late Sir Henry Wellcome, creating the Trust which we administer, empowers us to make grants for the foundation or extension of museums dealing with medical science or research, provided that any such foundation or extension is suitably associated in its title with the name of the testator.

We have now had further opportunity of considering the general plans which you put before us, together with the report by a member of our Trust, Mr. Martin Price, F.C.A., and have decided to offer to your rebuilding fund a sum to be applied to the construction and equipment of the three new museum floors which, in the plans which you showed us, were to be superimposed on a great hall in a new wing of the College. You mentioned upper and lower limits for the estimated cost of these three museum floors, from which we judged that a sum of £80,000 should be sufficient to enable the Royal College to undertake this extension of its museum accommodation. This is, accordingly, the sum which, on that assumption, we have decided to offer to your rebuilding fund.

As already mentioned, we are obliged by the terms of our Trust to make the offer conditional on the willingness of the College to associate the name "Wellcome" in some appropriate manner with the museum extension for which the gift would provide. We believe that there will be no difficulty in this, in view of the fact that Sir Henry Wellcome was himself an Honorary Fellow of the Royal College of Surgeons, and that he was himself directly responsible for the creation of important museums of the history of medicine and of medical science, which are still maintained by the Wellcome Foundation Ltd.

The Wellcome Trustees venture to hope that the acceptance of their offer by the Royal College of Surgeons will result in increased and progressive opportunities for friendly interchange between the museums of the Royal College and those to the creation and development of which Sir Henry Wellcome devoted so much of his interest in the later decades of his life.—Yours sincerely,

H. H. DALE,
Chairman of the Wellcome Trustees.

July 9, 1945.

The Council of the Royal College of Surgeons, at its meeting on July 12, received the offer of support from the Wellcome Trustees with great gratification, and decided to name one wing of the new buildings the "Sir Henry Wellcome Wing." It was particularly pleased to have his name identified with the College—not only on account of this munificent gift from the Trust but also because of its appreciation of Sir Henry Wellcome's great contributions to medical education and research. The Council was also glad of the opportunity thus afforded for close liaison between the museums of the Royal College and the great museums maintained by the Wellcome Foundation. This gift brings the amount so far received to £122,000 towards the total of £250,000 required to complete the restoration and development of the College.

WORK OF THE LISTER INSTITUTE

The report of the governing body of the Lister Institute of Preventive Medicine, above the signature of its chairman, Sir Henry Dale, P.R.S., covers only a dozen pages, but it reviews a large number of continuing studies by the staff in the pathological, biochemical, biophysical, and nutritional fields. Some of the work done under the auspices of the Institute has been recorded during the past year in the pages of this *Journal*—the work of Ellinger and others on nicotinamide and of MacLennan and Macfarlane on the treatment of gas gangrene.

Work on the typing of typhoid, paratyphoid, and food-poisoning bacilli with the Vi bacteriophage has been continued, and during the year one further Vi-phage type of the typhoid bacillus has been added to the list of new types or sub-types previously identified in the British Isles. The number of known Vi types or subtypes of the paratyphoid B bacillus indigenous to Britain remains five, but it is becoming apparent that hitherto unknown phage-types of typhoid and paratyphoid B bacilli are being introduced from abroad. Further progress has been made with the typing of *Bact. typhi-murium*, one of the most common causes of food-poisoning in this and in many other countries. Nine different Vi-phage types of this organism have been identified so far, and their epidemiological significance has been confirmed in all these outbreaks which have been investigated up to the present time. But the practical value of the bacteriophage typing of this organism is not as great as that of the typing of typhoid and paratyphoid B bacilli. Strains of the bacterium are often found to be devoid of the Vi antigen and cannot be typed by the bacteriophage method.

Two workers at the Institute have made some observations on the cardiac hypertrophy in the rabbit induced by an arteriovenous anastomosis. Following such an anastomosis, the weight of the heart in many instances is doubled. If the anastomosis is removed when the hypertrophy has been established for about two months, the weight of the heart quickly returns to a normal value, indicating that the hypertrophy produced by such an anastomosis is physiological in type. In certain animals, however, the hypertrophy does not disappear, suggesting that it may be pathological, and the matter is being investigated further.

Vaccinia Virus Studies

Pooled samples of serum from recently vaccinated persons have been examined to determine the time after vaccination at which the highest titres of virus-neutralizing antibody can be obtained. These tests indicate that the most potent sera are likely to be obtained during the third and fourth weeks after vaccination, but that no marked fall in potency occurs up to the end of the sixth week. The observations were undertaken as a preliminary to the collection of such serum and its storage in the dried state for therapeutic trial in the complications following vaccination, and possibly in smallpox.

A number of biochemical and biophysical studies are set out in the report, none the less interesting because in most cases definite results have not as yet been achieved. One practical development has been the elaboration of a tray-type drier capable of reducing the solid content of 5 litres of fluid to a powder of the same apparent volume and a residual moisture content of 2% in 15 hours. An indication of the optimum operating conditions for this plant has been obtained by a study of the drying of calcium penicillin, human plasma, and human milk. On the basis of this experience a large-scale plant has been erected by Imperial Chemical Industries at Manchester for the drying of penicillin.

Nutritional Studies

Some further work has been done at the Institute on the potato. A definite deterioration in the nutritive value of the nitrogenous constituents was found to occur when potatoes were stored for several months in a clamp; this was less marked when storage took place in a chamber with temperature controlled at 5° C. Study has been continued of the potato protein tuberin and the non-protein nitrogenous materials in the expressed juice. Evidence has been obtained of the existence of an additional unrecognized protein, but so far separation has not been effected. In connexion with the vitamin-A content of potatoes it has been found that rats can survive indefinitely with no, or very slight, skin lesions of vitamin-A deficiency, on a diet composed almost wholly of potato and with no other source of this vitamin.

A human experiment on deprivation of vitamin A, which began in July, 1942, at Sheffield, was concluded last year, and it was found that some of the subjects showed little evidence of depletion after two years of the deficient diet, though others had well-marked signs. The whole of the results of blood tests, food and faeces tests, and tests for capacity for dark adaptation have been tabulated and analysed and are being prepared for publication. The long-suffering subjects have been transferred to an experiment on the deprivation of vitamin D.

An experiment on yeast showed that while the proteins in dried yeast were much inferior to those of whole wheat, a mixture of the two was superior to the latter. The nitrogenous substances in domestic " beef tea " possess no growth-promoting value, but when combined with those of white flour they provide a mixture whose nutritive value is much superior to that of white-flour proteins fed alone. The supplementary action which the nitrogenous substances in beef extract and yeast have for cereal proteins is thought to be due to the high content of these nitrogenous substances in respect of the essential amino-acid lysine, in which cereal proteins are relatively deficient.

A note is appended to the report about the National Collection of Type Cultures, which is accommodated at the Institute's laboratories at Elstree. During the year under review over 4,500 cultures were distributed, and some 200 strains lodged for maintenance or investigation.

ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE

Pension, Scholarships, and Grants

The Council of Epsom College in December will award a France Pension of £30 per annum to a necessitous medical man, fully 55 years of age, who has been registered for five years, and who is in need of help.

The Council will also award St. Anne's Scholarships to girls attending Church of England Schools. Candidates must be fully 9 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school chosen.

Educational grants will also be available in November from the Sherman Bigg Fund for children of either sex. These grants are not restricted to orphans, or to members of any religious denomination, but candidates must be of public school age and in need of such help.

Available from the Eastes Trust are grants for the relief of registered members of the profession of any age, their widows and orphans, and educational assistance for daughters or, failing them, sons of deceased male members, or for full orphans, one or both of whose parents were members of the profession.

Forms of application for the vacant pension, scholarships, and grants can be obtained from the secretary, at the Secretary's Office, Epsom College, Surrey, and must be completed and returned by Sept. 15.

SCOTTISH MEDICAL WAR COMMITTEES

Lord Rosebery's Appreciation

The Scottish Central Medical War Committee has received the following letter from Lord Rosebery, Secretary of State for Scotland:

Dear Professor Sydney Smith,

At this stage in the work of the Scottish Central Medical War Committee, when the emphasis is shifting from the selection of medical practitioners for an expanding Navy, Army, and Air Force to the rebuilding of civilian services, I feel it is appropriate for me to express the Government's grateful thanks for the valuable contribution to victory in Europe represented by the labour of members and officers of the Scottish Central Medical War Committee and of Local Medical War Committees throughout Scotland.

The needs of the Forces reached a high level, and the Government relied upon your Committee to allot to each of the civilian services such contributions towards meeting these needs as would least prejudice the security of the home front. General practice, the hospitals, and the public services, as well as teaching, research, and other fields, have all yielded up their quotas; and the war against Germany has been won without serious dislocation at home. Not only the doctors who went away, but also those left behind in general practice and elsewhere, have borne a severe burden, and to them too I convey the Government's appreciation and thanks for their untiring labours.

The Committee's work is not yet done, and I am confident that they will tackle the problems of the future with the same energy and success as they have tackled those of the last six years.

Yours sincerely,

St. Andrew's House, Edinburgh, 1. ROSEBERY.

Reports of Societies

FOOD AND WOUNDS

The Nutrition Society held a conference on nutritional factors affecting wound healing at the London School of Hygiene on May 26, with Prof. J. R. **LEARMONTH** presiding.

Protein Loss

Dr. D. P. **CUTHBERTSON** spoke first on dietary protein in relation to convalescence from injury. Depletion of protein after injury had several causes, such as loss of the damaged tissues, loss of blood or exudate, loss by atrophy, and loss by excessive katabolism, due either to the injury or to superimposed infection. Thus the losses during the first 10 days caused by a severe burn covering 60% of the surface of the body might be assessed at 700 g. in the destruction of the skin and underlying tissues, 600 g. in exudation from the weeping surface, 700–800 g. through katabolic reaction to the trauma, and 100 g. through atrophy. The total loss was therefore more than 2 kg. of protein under these headings alone. In addition protein might sometimes be lost as the result of coccal infections during the first week, and of abundant mixed coccal and bacillary infections when the necrotic tissues were separating during the second to fourth weeks. Skin grafting might add to the deficit.

In injuries such as fractures and dislocations of the bones no tissues were lost by destruction or exudation, but the excess of katabolism, which reached its maximum between the fourth and eighth days, was still considerable. Since the days of Hunter it had been assumed that the body's reactions to injury worked in the direction of initiating a cure. The increase in protein katabolism, which also occurred in fever, probably indicated a raid on the protein reserves of the body in order to mobilize amino-acids specially required for the process of healing. Dietary measures to enable the body to make good the protein loss were therefore important. In the uninjured subject the katabolism of protein might be reduced by overfeeding with either a mixed diet or with extra carbohydrate: When the food intake exceeded the metabolic requirement protein and fat were stored more easily than carbohydrate, with the result that the last was preferentially katabolized. At the height of the katabolic phase after fractures, however, even a diet rich in protein and giving 5,000 calories failed to prevent a negative nitrogen balance. In serious cases blood, plasma, or serum should be administered to make good the loss. There was, indeed, no increase in nitrogen excretion in rats which had been starved of protein, or in malnourished human subjects, but this was merely an indication of the failure of the healing processes. After injury in normal subjects there was often severe anaemia, and appropriate steps should be taken if the haemoglobin level fell below 60%.

At the conclusion of the stage of protein katabolism the patient entered a period when through lack of appetite the loss of protein might not be made good quickly enough. The patient should be encouraged to eat as much as he conveniently could, and in convalescence the protein intake should be 150 to 200 g. a day, with enough carbohydrate and fat to permit the maximum anabolism of tissue protein. Milk (particularly evaporated), cheese, eggs, poultry, meat, and fish should be given to supply animal and cereals to supply vegetable proteins. In facio-maxillary injuries the diet might be given through a tube as a mash made from blocks of dehydrated food. Parenteral feeding must always be regarded as a temporary substitute for normal eating, but complete alimentation with hydrolysed casein and glucose for as long as 40 days had been recorded. Casein hydrolysates were usually prepared in 5% concentration with 5% glucose, and care must be taken to avoid local thrombosis. Daily doses of aneurin 2 mg., riboflavin 2 mg., nicotinic acid 20 mg., and ascorbic acid 50 mg., might be given if this form of nutrition had to be continued over a long period.

Dr. P. B. Croft described his experiments with Prof. R. A. Peters on nitrogen loss after thermal burns. When rats which received a diet containing 10% casein and 10% dried yeast as sources of protein were scalded with hot water there was an increased excretion of nitrogen in the urine, which was maintained for at least 10 days and was accompanied by loss of body weight. By raising the casein in the diet to 18.2%, however, both the increased excretion of nitrogen and loss in weight were prevented. When the effects of various amino-acids in preventing the excretion of nitrogen were examined a supplement of 1% of methionine was found to be effective, whereas other amino-acids were ineffective. It was natural to think that the beneficial action of methionine might be exerted either because of its high sulphur content or because of some role, such as methylation, in the liver.

Capt. J. A. F. Stevenson, R.C.A.M.C., in nitrogen-balance studies in acute diseases such as influenza, colds, and conjunctivitis, had found that protein katabolism was increased just as after trauma. In his experience the period of excessive protein katabolism was followed by a period of anabolism, during which the urinary nitrogen fell below normal. While the value of maintaining nutrition at a high level during the katabolic phase was open to question, the benefit of a liberal diet during the anabolic phase was beyond dispute.

Dr. B. S. Platt gave an account of his work on the relation of diet to the incidence of tropical ulcers. No ulcers were found in the population of Newfoundland, but a high incidence was found in Barbados, and higher still in Gambia. The distribution of dry skin and of "crackled" skin was similar. Examination of the diet in the three regions showed no correlation of the incidence of ulcers with the intake of vitamins, but suggested that low protein was a significant factor. The intake of methionine in some tropical diets might be only a quarter of that in European diets. Dr. Dagmar Wilson referred to her observations in India on the roughening and ulceration of the skin found in those leper colonies where the diet consisted mainly of rice. Lepers receiving better diets, which included milk or in which wheat was substituted for rice, did not have these skin abnormalities.

Vitamin-C Deficiency

Drs. J. F. Danielli, H. B. Fell, and E. Kodicek described the histological effects of partial vitamin-C deficiency on phosphatase formation in experimental skin wounds. The distribution of the enzyme was studied by Gomori's histochemical method, which could be applied to ordinary paraffin sections. In the healing of wounds in normal guinea-pigs there were two peaks in phosphatase activity. The first reached its height within a few days after wounding, and coincided with the invasion of the wound with leucocytes. The second peak was associated with the differentiation of collagenous fibrous tissue, and was usually at its maximum between the twenty-first and twenty-eighth days after wounding. In acute deficiency of vitamin C the first peak of phosphatase activity was not affected, but the second was suppressed. Though the wound became fully epithelized it was oedematous and haemorrhagic, and collagen was either absent or highly abnormal. To test the effect of partial deficiency of vitamin C, guinea-pigs were first kept on a scorbutic diet for 9 days and then given graded daily doses of ascorbic acid. Standardized wounds were made with a rotating knife 24 days after the commencement of dosing, and the animals were then killed 28 days after wounding—i.e., at about the time of the second peak in phosphatase activity. With doses of 5 mg. and 10 mg. both healing and phosphatase activity were virtually normal. With 2-mg. doses phosphatase activity was subnormal, and the wound was enlarged, but the intercellular fibres were more numerous and better differentiated than in complete deficiency. With doses of 1 mg. or under the wound was filled with spongy haemorrhagic material, though both the intercellular material and phosphatase reaction were slightly less abnormal than in acute deficiency. It was obvious, therefore, that the doses of ascorbic acid necessary for the efficient healing of wounds were many times greater than those necessary to maintain growth or to prevent scurvy.

Drs. P. D. F. Murray and E. Kodicek dealt with the effect on bone repair of partial deficiency of vitamin C. In unwounded guinea-pigs partially deprived of the vitamin the incidence of hyperostosis was 23%. The muscles were often swollen, with hyperplasia of the connective tissues, and ankylosis of the knee-joints was common. Other animals on the same diet were wounded by fracturing a fibula without open operation. Hyperostosis was found in 84% of this group. The callus produced was smaller than in normal animals, and the union of the fractured ends was probably delayed. If fractures were inflicted on normal guinea-pigs, and they were allowed to heal before the animals were restricted to diets deficient in vitamin C or D, or in both, no evidence of the reopening of the callus was detected.

Dr. Geoffrey H. Bourne's paper on the role of vitamin C in healing wounds was read by Dr. L. J. Harris. Guinea-pigs were kept for one week on a scorbutic diet, which in some groups was supplemented with graded doses of ascorbic acid. To study the healing of surface wounds two quarter-inch cuts were then inflicted, one on each flank. After another week the animals were killed, and the excised scars were examined both histologically and for tensile strength. With doses of 0–2 mg. of ascorbic acid the tensile strength increased with the magnitude of the dose, but raising the daily dose to 30 mg. caused no further improvement. It was clear, therefore, that ascorbic acid affected the strength of wounds, that saturation of the organism was not necessary, and that loss of tensile strength occurred with doses of vitamin sufficient to prevent the symptoms of scurvy. Histological studies confirmed that the weakening of wounds was essentially due to failure in collagen formation. The healing of wounds in bones was investigated by boring a small hole in each femur with a dentist's twist drill, full aseptic precautions being taken. After one week had been allowed for healing the animals were killed, and the femurs were decalcified and sections of the wounded areas prepared. The extent to which the holes had been filled up with trabeculae was then studied by an ingenious optical method. With graded doses of ascorbic acid the response increased between the levels of 0 and 1 mg., but higher doses had little further effect. A slightly greater formation of trabeculae was observed after dosing with calcium ascorbate than with the free acid.

Dr. J. Waterlow remarked that according to Dr. Pemberton little difference in the tensile strength of wounds could be found between normal human beings and vitamin-C-deficient volunteers when the lesions were examined 10 days after infliction. From Dr. Fell's sections of guinea-pigs' wounds, moreover, it appeared that the greatest differences between normal and deficient animals did not appear until after 21 to 28 days. It was rather surprising, therefore, that Dr. Bourne should have noticed differences in tensile strength only 7 days after wounding. Dr. BERGEL drew attention to the claim of Prof. Campbell and Dr. Cooke that in practical dentistry the administration of a large dose of ascorbic acid before the extraction of teeth greatly accelerated the healing of the gums.

Prof. LEARMONTH, in commenting on the work of the conference, stressed the desirability of nutritional preparation of patients awaiting admission to hospital for operation. If all patients could be as well nourished as possible before entry, the hospital would be relieved of responsibility in this respect. In hospital the feeding of patients with mixtures of amino-acids might have special value when necessity demanded, but the administration of nutrients by tubes was psychologically undesirable. The most urgent need was for an improvement in the ordinary hospital diet. Trained dietitians should be attached to all hospitals, and should ensure that the food was not only nutritious and well cooked but in keeping with local dietary customs and tastes.

Correspondence

The Position of Medical Research

SIR,—Dr. J. H. Hannan (July 7, p. 29) expresses surprise that, so little attention has been paid to medical research in proposals for the health programme of the future. Since the only way to impress a point of view is to go on repeating it I make no apology for stating that the planning of medical research should be on a nation-wide scale. In a letter in the *Journal* of April 22, 1944 (p. 572), I revealed that the financial side of medical research was very unsatisfactory. The Medical Research Council (M.R.C.), which serves such a useful purpose, receives an annual grant of £215,000 from the Treasury. This meagre financial support is hopelessly inadequate. It is up to the profession to organize and clamour for more money with which to conduct research work. The Government can, of course, afford a much larger sum.

Politicians know very little about medical research, and it would be worth while informing them that it has saved thousands of lives. Malaria, yellow fever, smallpox, as well as other diseases, all bow their heads before science; and tuberculosis, the venereal diseases, and diphtheria are also gradually giving way to the conquering strides of science. They could be told that if our great cities were deprived of the protection of medical science, civilization would fall back five centuries, pestilences would return, and epidemics sweep the country and destroy thousands of innocent lives. Medical research by discovering the vitamins proved that the lack of these essential food factors gives rise to such diseases as rickets, scurvy, beri-beri, and pellagra. The work that has been done on the general hygiene of our city life—the purification of water, the disposal and treatment of sewage, the control of food manufacture by means of food analysis and inspection, and the detection of adulteration, to recall but a few examples—could be mentioned to illustrate how science benefits living conditions. The achievements of British medicine are great and manifold, and it would require someone more competent than I to describe them. The miracle is not that so little has been accomplished but that so much has been achieved in spite of lack of funds. The latest achievement—penicillin—has attracted world-wide attention. The work of Sir Alexander Fleming and his school is so well known that it hardly needs to be mentioned.

It is unfortunate that the profession itself has remained aloof in political matters and not urged the Government to be more helpful in utilizing medical research for solving many of the problems which jeopardize health. The attitude of the Government towards medical research is reflected in their meagre allowance of less than a quarter of a million pounds per annum. If people are to be liberated from the fetters of poverty, ignorance, and illness, medical research should be in the forefront of future planning by the Government. Yet, as Dr. Hannan has pointed out, little or no attention is being paid to research. It goes without saying that diseases should be wiped out and medical men mobilized to tackle problems still unsolved. Is it not surprising, then, that less money is available for research in this country than in either the United States or the Soviet Union?

The M.R.C. represents this country's efforts to attack the most difficult problems of medicine in a planned way. The M.R.C., moreover, is the high school for the training of young research workers, but at the present time most workers are obliged to spend half their time in practice in order to earn a living. The young man who has no private income finds it difficult to enter upon a career devoted to research. In spite of the fellowships offered by the M.R.C. and positions available in research departments of universities, where research as well as educational work is carried on, many young men have to live for years on minimum salaries that do not allow them to support a family. The M.R.C. has become the important planning agency in the field of medicine, and it has amply demonstrated the wisdom of having research directed by a group of eminent scientists rather than by philanthropists and business men who cannot possibly have a sound judgment in medical matters. Medical research is not a luxury supported by philanthropic agencies, but it is, on the contrary, the most powerful instrument that the country possesses for ameliorating the lot of mankind and ensuring human harmony.

A difficulty which progressive medicine has encountered, particularly during the war, has been the shortage of paper, which has made the publishing of medical works very difficult. There is now a great shortage of books and literature because the demand for books and journals is almost inexhaustible. The publication of a medical book should not depend on its commercial value; if it is worth being printed—and nobody but doctors can decide—the book should be published. Surely the Government can allow medical publishers more paper now when the need is so great and urgent. A liberal enough allowance was made to prospective Parliamentary candidates! The British Navy, Army, and Air Force played a magnificent part in conquering Hitlerite Germany. Now let us utilize medical man-power to make the world a better place in which to live. For, to repeat the words that Herbert Spencer promulgated in his epigram: "Science is for Life, not Life for Science."—I am, etc.,

Preston Hall Hospital, Maidstone. GEORGE R. W. N. LUNTZ.

Newer Concepts of Breast-feeding

SIR,—Replying to Dr. Eric Coldrey (April 14, p. 530) it strikes me that he wishes to stampede us into thinking that the panacea for successful breast-feeding is enthusiasm on the part of the mother and strict non-interference. Such advice fails hopelessly in actual practice. Most mothers are very enthusiastic to breast-feed, and yet see the countless number that fail! The explanation is simply this: in addition to enthusiasm it is essential that the mother should be instructed and taught *how* to breast-feed successfully. Dr. Coldrey completely fails to see this vital factor, but instead points an accusing finger at the "sick visitor, the mother, the mother-in-law, neighbour," etc.

Let us face the truth. The fault lies mainly with the medical profession. The profession has failed to recognize that successful breast-feeding is not accomplished by enthusiasm alone. Lactation is indeed a fine art requiring the closest study. There is in breast-feeding, as in everything else, a right way and a wrong way. First and foremost it is imperative for the doctor to be equipped with a thorough knowledge and clear understanding of the physiology and the clinical aspects of this most important subject. To the doctor the mechanism of the lactating breast and the nipple in all its variations must be made crystal clear. Only then will he be able to enlighten the mother and help her solve her feeding problem; only then shall we find more mothers breast-feeding successfully. Without such knowledge it is a case of the blind leading the blind.

Fifteen years of close observation of all sorts of methods of breast-feeding in an extensive paediatric practice have convinced me absolutely that the technique I employ and described in the *Journal* (March 31, p. 441) is the easiest, the most natural, and the most satisfactory. The newer concepts mentioned are clinically and biologically sound and the *modus operandi* is simplicity itself.—I am, etc.,

Johannesburg. M. WITKIN.

The Filigree Operation

Sir,—The *Journal* of June 9 has belatedly come to hand. The relevancy of Mr. Greenwood's quotation (p. 820) from Burke escapes me: is it to be inferred that the present-day advocates of the filigree are, like Livy and Virgil, Raphael or Michelangelo, to be admired by all the learned, or merely that the filigree operation is like the Constitution of England, to be venerated if not comprehended? I do not intend to judge of the former, and as to the latter I am sure that nowadays the filigree operation is hardly a constitutional, established practice.

I spoke disparagingly neither of the filigree operation nor of Mr. Coles's results, but pointed out that the comparison of figures made was unsound on two grounds: (1) Individual figures are not comparable with collective figures. Mr. Coles's 3% cannot be compared with "over 12% representative of British surgery as a whole," nor Mr. Greenwood's individual 1% recurrence rate with the collective or group figure for the series of Page and McPherson, which were operated upon by several surgeons. (2) The follow-ups should be comparable and equally searching. In neither Mr. Coles's nor Mr. Greenwood's series are details given of the percentage of cases actually traced and examined or at what intervals after operation.

An ideal follow-up would be fully comprehensive: 100% of patients seen and examined, say, 4 years after operation. This in unattainable, but naturally the means available for following up police cases is likely to lead and did lead to a very high percentage being traced. The more cases examined, naturally, the more recurrences one finds. The follow-up must be active: it is insufficient to rely on patients reporting by themselves or sending a postcard—they may be "bombed out" or dead.

The filigree operation may be the answer to the hernia problem, but I still do not think that the figures available nor the comparisons that have been made prove it, or warrant a return to an operation considered unsatisfactory in the past.—I am, etc.,

J. B. Kinmonth,
Squad. Ldr., R.A.F.V.R.: Surgical Specialist.

Effects of Tobacco Smoking on Health

Sir,—As the smoking of tobacco in this country has increased criticism of smoking has decreased, and to-day discussion of the facts about the effects of smoking on health is "not done"—i.e., is taboo.

The majority of people, even medical men, are, however, scarcely conscious of the existence of the "tobacco taboo." Smokers repress their thoughts about the ill effects of smoking, and thus they observe the tobacco taboo unconsciously; and the compliance of non-smokers, impressed usually at an early age, also tends to become habitual and largely unconscious. Increased publicity given to matters of health of late years has by contrast served to accentuate the rarity of talks, or articles, on the effects of smoking on health.

Although the facts are taboo, rationalizations, even untruths, about smoking circulate freely. The fundamental facts are that tobacco is a drug, and smoking a drug addiction (more precisely, a means of administering a drug of addiction), but these are seldom mentioned. Tobacco is spoken of freely—but as a luxury; and smoking is mentioned freely—but as a habit. Drugs of addiction are not, however, luxuries, and habit merely supplements the main urge to smoke—viz., an inner craving. Drug addiction, and therefore tobacco smoking, is a disease—an intoxication like the majority of diseases although the specific toxins are not bacterial. It is significant that this important disease is not referred to in standard textbooks on medicine—e.g., Beaumont, Osler, Price, etc.—except as a predisposing cause of other diseases.

Recognition of smoking as a disease has been impeded by smokers repressing the occurrence of unpleasant symptoms following the initial agreeable action of tobacco on addicts. Observation and interrogation of over 500 individuals cured of smoking has suggested that these symptoms include depression, apathy, moral deterioration; loss of energy, of appetite, of weight, and of sexual potency. Smokers only become aware of these remote effects as a rule when smoking has been given up, and even then persisting craving for tobacco may cause them to disregard or make light of their improvement in health. The alleged absence or insignificance of such improvement (not confirmed by observation) is sometimes advanced to extenuate a relapse to smoking. When symptoms cannot be repressed, as in the case of troublesome cough or clearing the throat, smokers often rationalize the cause: I have pointed out in a previous communication (Johnston, 1942) that they often attribute their cough to a variety of causes other than smoking and "take all manner of useless medicaments while rejecting and even resenting the suggestion that smoking might be responsible."

In repressing and rationalizing facts adverse to smoking, smokers deceive themselves and communicate their deception to non-smokers. In this respect tobaccoism is clearly a communicable disease, spread by the example, the encouragement (e.g., the proffered cigarette), and by the communicated deception of smokers (i.e., by "psychological infection"). The frequency of references to the comforting action of tobacco (without any indication of its repressed unpleasant effects), and the scale of tobacco advertisements (all of which suggest that it is harmless, normal, manly, or attractive to smoke a particular brand), give some indication of the volume of deception to which non-smokers (and smokers) are exposed. The pandemic of smoking to-day testifies to the efficacy of such "infection."

Owing to the resistance of smokers I have been unable up to now to ascertain the time lost on account of illness by comparable groups of smokers and non-smokers on an adequate scale. Some indication of the total harm caused to health by smoking can, however, be deduced from its effects on mortality. The following figures were published by Raymond Pearl in 1938:

Table I

The death rate (1,000qx) and survivorship (lx) functions at 5-year intervals, starting at the age of 30, of non-users of tobacco, moderate smokers, and heavy smokers.

Age	Non-users		Moderate Smokers		Heavy Smokers	
30 ..	8·18	100,000	7·86	100,000	16·89	100,000
35 ..	8·78	95,883	9·63	95,804	21·27	90,943
40 ..	10·01	91,546	11·89	90,883	23·91	81,191
45 ..	12·04	86,730	14·80	85,129	25·69	71,665
50 ..	15·16	81,160	18·61	78,436	27·49	62,699
55 ..	19·92	74,538	23·67	70,712	30·09	54,277
60 ..	26·73	66,564	30·49	61,911	34·29	46,226
65 ..	36·88	57,018	39·83	52,082	41·20	38,328
70 ..	51·69	45,919	52·84	41,431	52·72	30,393
75 ..	73·02	33,767	71·28	30,455	72·33	22,388
Total investigated	2,094		2,814		1,905	

Age groups over 75 are excluded by me from Pearl's table.

A personal investigation of the smoking of an unselected series of men and women of a wage-earning community in England in 1936–7 provided the following analysis:

Table II

Total		Non-smokers	Moderate Smokers	Heavy Smokers
Men	804	89 (11%)	270 (34%)	445 (55%)
Women	762	580 (76%)	151 (20%)	31 (4%)

Heavy smokers smoked more, moderate smokers less, than 10 cigarettes or ½ oz. pipe tobacco per day.

It will be observed (Table I) that the mortality of heavy smokers from all causes between the ages of 30 and 45 is more than double that of non-smokers; also that the effects of smoking on mortality diminish as age advances. Since 55% of our male population and 4% of our female population were heavy smokers in 1937 (Table II) and the consumption of tobacco in this country in 1944 was 34% higher than in 1937, it is clear that smoking is an important cause of mortality and that active measures to combat tobaccoism are urgently called for.

I should like to express my gratitude to Dr. James L. Halliday, Department of Health for Scotland, for valuable criticism.—I am, etc.,

Wallasey. Lennox Johnston.

Trichlorethylene in Midwifery

SIR,—I have read Dr. D. R. Cairns's letter (June 23, p. 885) with interest. His experience with trichlorethylene in midwifery is similar to mine. However, I think that some caution should be exercised, and it is my practice not to use trichlorethylene in patients who have been on a very low protein diet. This is, of course, to avoid the possibility of liver damage. When labour has been difficult and prolonged I think that extra care should be used to give only small amounts of the drug in order to ensure that the tone of the uterus does not suffer.

I see no reason why an inhaler such as Freedman's should not be used by midwives providing they have received adequate instruction; but I would suggest that Clover's or Hewitt's modification will give better results in the hands of the practitioner. In my letter in the *Journal* of March 24 (p. 422) I described my experiences using Hewitt's wide-bore inhaler. The great advantage is, of course, that it allows for fine adjustment of the concentration of vapours one desires to use. Differences in individuals in their response to anaesthetics are too well known to need description.—I am, etc.,

Eastcote, Middlesex. D. C. DEVITT.

Mono-articular Osteo-arthritis of the Hip

SIR,—Mr. Grant Waugh is to be congratulated on his results with acid injection of the osteo-arthritic hip (June 23, p. 873) and on his temerity in publishing them. For he will know well enough that intra-articular injection is regarded as a rather improper procedure, since it transgresses (in some manner never quite clear to me) the rules of civilized warfare—against disease. But having to my shame injected rheumatic joints some quarter of a million times, with constant failure in the case of the hip-joint, I applaud the man who offers sober and solid proof that he can powerfully help persons suffering from this gravest and most disabling of all osteo-arthritic lesions. For this reason it would seem most unfortunate if Dr. Aldred-Brown's attempt (July 7, p. 28) to explain away the results of intra-articular medication should deter others from trying the matter out in their own practice. It must be within the competence of few to attain the success hinted at by Dr. Aldred-Brown as won by simple exercises, but acid injection can be tried out by all. I shall try it myself, having over many years observed uniform failure of exercises, simple and otherwise, in obviously less skilful hands than those of Dr. Aldred-Brown. —I am, etc.,

London, W. G. LAUGHTON SCOTT.

SIR,—I am the last to minimize the value of non-weight-bearing exercises in this condition; but if Dr. Aldred-Brown will inject one joint in a bilateral case and use the other as a control he will, I think, find that the rate of recovery to a considerable degree of functional efficiency is very much more rapid in the injected joint than in the other.—I am, etc.,

Sunderland. W. GRANT WAUGH.

Procedure to Stop Anginal and Asthmatic Attacks

SIR,—Peller published in 1923 an account of the therapeutic effect following the obstruction of the venous return of the upper and lower extremities on cardiac asthma and angina pectoris. He observed a decrease of the systolic and diastolic pressure within a few minutes as a result of this procedure. He did not mention who was the first to introduce this method.

The therapeutic effect following venous congestion of both extremities (arms and legs) is really startling. Since Peller's publication I have used this simple method in acute cases of so-called bronchial asthma as well, with the same surprising result—the immediate cessation of the attack. Only the venous circulation should be obstructed, not the arterial.

Peller believed that by reducing the amount of blood returning to the right side of the heart and the lungs so that the dilated right auricle had a chance to recover its tone and in decreasing the amount of venous blood reaching the lungs the circulation and gaseous exchange in this organ were improved. There may, however, be another explanation for this startling effect, so far as I know not mentioned before. Having studied the varicose syndrome of the legs and the rectum with their sometimes agonizing pains and cramps, it struck me that there may be an analogy between these clinical symptoms and those of angina pectoris, cardiac and bronchial asthma.

Supposing the right auricle is being overloaded with venous blood, the auricle distended, and the muscle losing its tone, we may then expect there to be back pressure into the coronary sinuses. Now if the venous return from the heart proper suffers, following distension of the heart veins there will be temporary "cramps," then loss of muscle tone, and later atrophy of the myocardium due to anoxaemia and intoxication of the heart muscle. This leads me to propose, therefore, that the syndrome complex called in our present clinical language "asthma" and "angina" may be caused by a functional disturbance of the venous return from the heart muscle proper, due to distension of the right auricle. I feel that the pathological changes which may or may not be present in the coronary arteries—i.e., coronary sclerosis—are late changes, and that the arterial changes are not primary but the result of a functional disturbance of the venous return from the heart muscle.

I would like to hear of the experiences of others using this simple procedure, and, if possible, a better explanation of the startling effect produced. The above procedure is simple, can be repeated in following attacks, saves morphine, and is easily performed by the nursing staff using four elastic bandages or pneumatic tourniquets.—I am, etc.,

London, W.1. KASPER BLOND.

Electro-convulsive Therapy Apparatus

SIR,—It was with some astonishment that we read the letter in your issue of June 30, regarding an E.C.T. instrument we described recently. Your correspondent, who styles himself "S.M.I.E.E.," which we understand connotes student member of the Institute of Electrical Engineers, makes the most extravagant statements in regard to the instrument, and in doing so displays a lack of knowledge of the practical problems of shock therapy with which it is concerned. We feel obliged to answer his criticisms lest they should mislead other readers.

He states that the apparatus is not capable of "delivering exactly the required voltage for an exact period of time measured in 1/10th of a second," and has not a margin of electrical safety suitable for medical work. Yet it was precisely with these requirements in mind that the instrument was developed. The time intervals obtainable with the apparatus are spaced by 1/10th second, ranging from 0.1 to 1 second—intervals which are *more* than sufficiently close for the accuracy to which dosages can be prescribed, and which cover a greater range of times than is required in practice. The voltage steps were chosen with the same consideration. To imply that it is an advantage to be able to deliver a shock lasting, say, for 0.431 second is simply ludicrous, and merely leads one away from the all-important requirement of simplicity and fool-proof operation. The telephone dial was chosen because it *has* been proved to have an extremely high degree of reliability; it is in fact considerably more trustworthy than most relays and condensers.

Voltage regulation is criticized similarly (though without any detailed knowledge of the transformer used). The voltage drop on load is in fact only a few per cent., and does not detract in any way from the ability of the apparatus to supply the required shock at a reasonably closely prescribed voltage.

Earthing of the patient in such treatment is largely a matter of opinion. If the patient is treated on an insulating couch then earthing of the secondary winding gives protection against possible faults in the transformer or other parts of the circuit. If, however, there is a likelihood of the patient's touching an earthed conductor while being treated it is better to keep the secondary winding free. This can be readily achieved by disconnecting a lead in the apparatus; it is not in any way fundamental to the circuit.

The use of a 1 mA meter for the "test" circuit has been found quite satisfactory with the size of electrodes we use, and we see no grounds for replacing this by a much more costly instrument. The design has been chosen to meet the practical needs, not the theoretical ideals which so easily obscure the main issue.

We would, in conclusion, point out that we have not been unmindful of the many factors to which your correspondent has so kindly drawn our attention. There is no need for him to talk of "fatal complications," "convulsion trauma," and "accidental electrocution," and to imply that these dreadful results can be avoided only if one purchases a machine which is heavy, bulky, and probably expensive, due to the fact that many of these embody a number of refinements of no practical value whatever.—We are, etc.,

A. SPENCER PATERSON.
F. T. FARMER.

Belsen Camp

SIR,—In the recent literature published on what has been done in Belsen Camp reference has been made to the excellent work of medical students, research teams, civilian workers, and combatant units, but so far no mention has been made of the work of the Army nursing sisters. Nursing officers of 32 C.C.S. and 9 Br. General Hospital were in the hospital area from the earliest days, and some account may be given of the conditions under which they worked.

The hospital was divided into blocks holding 150 beds, and subdivided into rooms of 4 to 8 patients; one sister was in charge of each block, helped by one British orderly and an inadequate number of internees later replaced by Germans. Patients were admitted at the rate of about 500 a day, beds consisting mainly of palliasses on the floor. It was estimated that about 80% had diarrhoea, most were confined to their palliasses, and there were 2 bed-pans to each block. The results can be imagined!

Food distribution was a major problem; all the patients had an insatiable hunger and were invariably dissatisfied with the amount they got; free fights between the different races were a common occurrence at meal-times. Hoarding was almost universal, and nearly every bed had mangled scraps of bread, butter, etc., hidden under the mattress or blankets. Deaths to begin with were numerous, and it was a common occurrence to find several dead in bed on the morning round. The patients themselves were miserable and emaciated to an almost unbelievable degree; they were entirely lacking in any form of self-respect and uninterested in anything except food. The language difficulty precluded conversation even with the workers, who had to be instructed in their duties by means of signs and demonstrations.

Working under these conditions in close and constant contact with the patients the Army sisters showed a willingness and initiative that deserve the highest praise, and the skill and cheerfulness with which they dealt with the patients, obstinately refusing to be put off by sights and smells, must be reckoned as a major factor in the rapid recovery, both mental and physical, of the patients under their care. It is to be noted that many of the sisters came to Belsen immediately following a hectic and gruelling time dealing with the casualties of the Rhine crossing, and at the end of nearly a year's service with the B.L.A.—We are, etc.,

HILDA ROBERTS,
Major, R.A.M.C.
PETRONELLA POTTER,
B.L.A. Capt., R.A.M.C.

Tuberculous Persons in Prisons

SIR,—I am horrified to read in the *Journal* of July 7 (p. 32) Sir Donald Somervell's statement in Parliament concerning tuberculous prisoners. He states that *where possible* the prisoners are employed in light gardening work. Does this mean, therefore, that if light work is not available then they are put to heavier manual labour? The statement, if I understand it rightly, does not lend itself to the interpretation that if "suitable" work is not found for them then the prisoners are excused from working altogether. The "special working parties" mentioned are arranged, he admits, with the purpose of segregating these cases of active tuberculosis from other prisoners who are free from infection, and not in order to relieve them of doing work which would accelerate the cours of the disease.

Surely every patient (even if he is a criminal) is entitled t all the medical and nursing care, which includes absolute rest so vitally necessary to cases of active phthisis. Or are we suc a degenerate nation that we can deliberately allow patients t suffer and die a premature death simply because they have bee guilty of some crime in the past, and consequently are considered no longer fit persons to receive adequate sanatoriun treatment?

Further, I am wondering in what degree (if at all) moder prison conditions could be accounted aetiological factors i tuberculosis in prisoners.—I am, etc.,

Aldershot. AUDREY ROBERTS.

Teaching of Physiology

SIR,—Dr. R. A. Gregory (July 7, p. 26) no doubt expect general commiseration on the fact that 30,000 cats were lost t his physiological abattoir in Liverpool last year. I, for one congratulate the R.S.P.C.A. on their vigilance, rank heres though it be to say so, and I can raise no enthusiasm over thos Continental physiologists with their revolting cruelties, thoug they were, it is true, only practised on small trussed-up animals

One cannot, of course, expect a professional physiologist t look at it in that way. After all, physiologists must live, an they have the common weakness of all specialists in having profound belief in the efficacy of their own nostrums; in thi case more, and ever more, physiology for the top-heav medical student. Will, we may ask with all respect to th professors, an increase in the kind of dilettante surgery whic goes on in a physiological laboratory improve the quality o the average doctor? One takes leave to doubt it. It used t require a "slaughter of the innocents" to prove that a muscl contracted when stimulated, whereas one has merely to dro a brick on to one's foot to make a whole host of muscles—facial, lingual, and skeletal—contract very smartly.

However, living perpetually in an atmosphere divorced fro human reality seems to make even simple facts difficult c perception. What is the objection to a competent demonstrat giving an exhibition of the main facts of experimental physic logy? This is far better than the maiming and mauling whic usually goes on in the average laboratory and the inconclusiv and unsatisfactory results which come from such bunglin How many of us have to leave hospital having left undon those things which ought to have been done, and having t make them good later on? If there are going to be any omissions in the welter of things required to be done by the medic student, then let it be in the sphere of physiology rather tha of clinical medicine, and our long-suffering patients may hav cause to be grateful for an increased knowledge in the doctors of what really matters.—I am, etc.,

Hove. G. L. DAVIES.

A Token of Thanksgiving

SIR,—As Honorary Treasurer of the Royal Medical Benevolent Fund, I recently received a letter from which I venture t quote the following words:

> "For many weeks I have been intending to send the enclos cheque for 50 guineas as a token of thanksgiving for the end the bombardment of London, the preservation of my wife and myse and our home, and the cessation of the fighting in Europe."

If it was more widely realized how heavy and burdenso have been the lives of the beneficiaries of the Fund during t years of the European War, there would be many who, havin a feeling of great thankfulness, would like by a "token to t Fund" to bring greater comfort and happiness into the liv of these old people now that peace is again in our own lan I should be so thankful to acknowledge, on behalf of t committee, any special donations that may be sent to me fro any who have the same feeling as our medical colleague wh has forwarded the first token of thanksgiving.—I am, etc.,

C. LUTHER BATTESON,
Honorary Treasurer, R.M.B.F.

1, Balliol House,
Manor Fields, Putney, S.W.15.

Identification of Epidemics

SIR,—The identification of epidemics described by our predecessors must always be speculative, but, in justice to the memory of a great epidemiologist, it is right to mention that most of the evidence quoted by Sir Henry Tidy (July 14, p. 63)—and a great deal more—is fully discussed in Hamer's *Milroy Lectures,* and it may be of interest to remind readers of the train of reasoning (*The Milroy Lectures on Epidemic Disease, etc.,* by W. H. Hamer, London, 1906, pp. 72, Bedford Press).

Both the symptoms reported and the physical signs observed in cases of illness during an epidemic or pandemic of influenza vary much (profuse sweating, for instance, is mentioned as a prominent feature in many famous epidemics—e.g., by Baker in the great influenza of 1762); but there is one criterion—whether one should call it statistical, epidemiological, or clinical, I am not quite sure—which applies to all great epidemics—namely, the dissociation of symptoms and physical signs at an early stage; the patients are much more ill than the physical signs would lead one to expect. A very good practitioner has said that if he were called to a number of patients taken suddenly ill with "colds" who were very much worse than anything he could find in the chest justified, he would know that influenza was epidemic. Now, apart from sweating sickness, there have been and continue to be odd outbursts of epidemic disease, Haffkrankheit, Bornholm disease, epidemic myalgia, etc., in which one has the features of sudden onset, very great severity, and variable symptomatology; also, of course, the agues, obscure nervous illnesses, and so on, to which Creighton, Crookshank, and others called attention.

Now Hamer, an enthusiastic admirer of Sydenham, wished to rationalize Sydenham's mysterious doctrine of epidemic constitutions, and suggested that these odd epidemics belonged to what he called the "setting" of a pandemic—they led up to, or followed after, a great explosion. How far he was successful is a matter of opinion. Personally I agree with Freind, who thought Sydenham's doctrine mythological, but it is quite certain that Hamer and Crookshank *did* make out a curious association in time between these odd epidemiological happenings and the emergence of a great epidemic of influenza. Vague as all this may be, it is valuable, because one of the wholly unsolved problems of pandemic influenza is what prepares the way. If there are indeed forerunners, perhaps with our present knowledge of virus we may reach an explanation.—I am, etc.,

MAJOR GREENWOOD.

The Services

Surg. Lieut. R. St. C. Mooney, R.N.V.R., has been awarded the D.S.C. for outstanding courage, tenacity, and devotion to duty when H.M.S. *Bedouin* was sunk in defence of a convoy to Malta.

Temp. Surg. Lieut. M. C. Connell, R.N.V.R., has been mentioned in dispatches for bravery, great endurance, and devotion to duty.

Temp. Surg. Lieut. George Smith, R.N.V.R., has been appointed M.B.E. (Military Division) for bravery and great devotion to duty, while serving in H.M.S. *Daffodil,* in refusing to leave his ship though seriously wounded himself in order that he might attend casualties.

Lieut. N. St. J. Hennessy, R.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in Burma.

The following appointments and awards have been announced in recognition of gallant and distinguished services in North-West Europe:

O.B.E. (Military Division).—Cols. W. A. Fraser and S. G. U. Shier; Lieut.-Cols. D. L. Maclean and E. F. Ross, R.C.A.M.C.

M.B.E. (Military Division).—Majors D. R. McCrimmon and E. I. Ostrey, R.C.A.M.C.

Bar to the M.C.—Capt. E. L. Moore, M.C., R.A.M.C.

M.C.—Major (Temp.) D. I. McCallum; Capts. W. Blair, J. Clark, P. Esmonde, A. I. D. Prentice, and T. McS. Wilson; Lieut. E. C. B. S. Keat, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died.—Lieut.-Col. Gilbert Cleary Babington, R.A.M.C., W/Capt. Alexander Prentice Thomson, R.A.M.C.

Obituary

A. R. LAURIE, C.B.E., M.B.

Dr. Alan R. Laurie, C.B.E., T.D., M.B., Ch.B., D.M.R.E., who died at his home in Derby on June 27, was a man of wide enthusiasms and many interests. His main professional work lay in radiology, and at the Derbyshire Royal Infirmary he and his friend, G. L. Stiles, formed a powerful team of clinical experience and wise interpretation.

A. L. S. writes:

Dr. Laurie's previous work as a general practitioner gave him an appreciation of and sympathy with the problems of radiology from the family doctor's side. He had a wide private consulting practice in radiology throughout Derby and Derbyshire, and apart from the hospitals in Derby to which he was radiologist he acted in a similar capacity to many smaller institutions throughout the county. He was also in charge of the Skin Department at the Derbyshire Royal Infirmary, and to attend his out-patients was an experience to remember—his unfailing good humour and wit, his courtesy and tenderness to the tiresome old "chronics," and the absence of bustle and boredom, produced a happy atmosphere not always obtained at out-patients.

Apart from his purely professional work I would say that his great interest lay in his Army associations. I was with him in the last war, when he was in turn adjutant to an R.A.M.C. training centre, medical officer to the 6th Yorks in France, and a vital and active member of the 34th Field Ambulance. In 1936 he became A.D.M.S. to the 46th (North Midland) Anti-Aircraft Division, following a highly successful period as O.C. 137th Field Ambulance, which he brought up to wartime strength and a high efficiency. Probably no man knew more of the medical service of the A.A. Forces generally than Dr. Laurie, and a C.B.E. was some recognition of the enormous amount of hard work, imagination, and detailed care that he put into this work.

As a sportsman he was versatile and keen: a cricketer of skill, a forceful batsman, and a brilliant fieldsman, he could have played for his county had he had the time. He obtained his blue at Edinburgh University for cricket and soccer, and he played soccer for a time with the Derbyshire Amateurs. He loved the country and his fishing and an hour at the local inn with men who always welcomed and respected him. The stage lost a fine actor in Dr. Laurie; he stage-managed and took parts in many performances of the Derby Branch of the British Shakespeare Society; and, in lighter vein, he produced shows for the nurses at the Derbyshire Royal Infirmary. Only a few of his friends knew the difficulties that he had been working under for a year or more. He was too vital and conscientious to take the rest that was necessary, and he had—perhaps happily—only a short period of invalidism before he died. "Peter" Laurie was a man of courage and vision, incapable of any meanness and generous in thought and deed, and friends from many walks of life mourn his loss. He leaves a widow and four daughters.

G. GREGORY KAYNE, M.D., M.R.C.P.

The premature death of Dr. G. Gregory Kayne at the age of 44 deprives workers in the field of tuberculosis of one of their most valued colleagues. Born on the Continent, he came in boyhood to this country, and subsequently entered St. Bartholomew's Hospital, qualifying in 1923. He gained the prize for the B.M.A. essay, proceeded to the degree of M.D.Lond., and became M.R.C.P. in 1927 and D.P.H. in 1936. After filling posts in general medicine and surgery he turned to the problems associated with tuberculosis, and these remained his absorbing interest for the rest of his life. After serving a period as assistant medical officer at the North Wales Sanatorium, he was appointed Dorothy Temple Cross Research Fellow in Tuberculosis by the Medical Research Council. This scholarship took him to most of the important centres of tuberculosis work in

Europe, and he became a colleague and friend of Savé, Hazemann, Armand-Delille, Wallgren, and other leading workers. He studied particularly preventive work, notably the B.C.G. vaccine and the "Grancher system," and wrote papers on both these subjects. His interests in the field were wide and his knowledge of the literature remarkably extensive. The last ten years of his life were spent in the service of the Middlesex County Council, first as deputy medical superintendent at Clare Hall, and then as tuberculosis medical officer at Hounslow.

Perhaps Kayne's greatest activity was shown as a writer. For some time he edited *Tubercle*, but his chief work was the book *Pulmonary Tuberculosis*, which he wrote with Pagel (for pathology) and O'Shaughnessy (for surgery), and edited. This important volume remains a sound guide for tuberculosis workers.

In council and committee his views were clearly and vigorously expounded; his wide knowledge, especially of foreign literature, was invaluable and was often put at the disposal of this *Journal*. He served on the Tuberculosis Committee of the M.R.C., and was a member of the Council of the Tuberculosis Association. Unsparing of himself, he often worked far into the night; at times his keenness perhaps made him forget that others might not keep pace with him. He overcame many hardships of early life, and battled with great personal difficulties in achieving a position where he did work of lasting value, which was honoured not only by his colleagues in this country but by the official recognition of the French Government.

A colleague writes:

In the death of Gregory Kayne phthisiology loses one of its most lively, industrious, and progressive promoters. His main interest and gift lay in the clear presentation of controversial problems. He was not the man to be satisfied with a superficial sifting of pros and cons, and he would never evade difficulties which could be covered up by brilliant diction, but would work on, after a day overflowing with professional duties, until he had found his way through the literature, whatever its magnitude. A thorough command of modern languages, an unusual capacity for logical thinking, and a critical understanding of the most urgent problems of tuberculosis enabled him to give masterly reviews of the B.C.G. question, of heredity and immunity in relation to tuberculosis, and of the control of tuberculosis in England. But it was on a multitude of personal observations collected in many countries that he could base his work on tuberculosis in home contacts, children and adults, which formed the nucleus of a comprehensive report on the prevention of tuberculosis in childhood with special reference to methods of separation—the main result of his work under a Dorothy Temple Cross scholarship awarded to him by the Medical Research Council. The same original material and technique of investigation are recognizable in Kayne's pioneer work on tuberculin—a series of papers starting with a comparison of old tuberculin with a preparation from a synthetic protein-free medium, which led up to the elaboration of the modern technique of the Pirquet-Mantoux test.

In the book on pulmonary tuberculosis jointly written with W. Pagel and L. O'Shaughnessy, Kayne visualized the work as an organic whole in which the various aspects should influence and penetrate each other, rather than an encyclopaedia in which they form independent and uncorrelated articles. If anything of this nature has been achieved, the credit goes to Kayne's able editorship and tireless co-ordinating, often restricting, but always stimulating energy. For a life so full of fruitful labour as that of Gregory Kayne there is no more fitting motto than the word of the sages: "The day is short, and the work is great; the labourers are sluggish and the reward is much, and the master of the house is urgent."

The sudden death of Dr. A. W. Matthew on May 27, just as he was taking leave of some friends, has filled many at St. Mary's Hospital and elsewhere with regret at the loss of one so staunch and loyal, while still in full activity at the age of 54. Matthew was a student at the London Hospital, and not long after qualification was swept into the war of 1914-18, in which he achieved the curious distinction of being the last man to be evacuated from Gallipoli at Suvla, where he had to stay with a party of sick and wounded. Afterwards he was severely wounded on the Somme and narrowly escaped the loss of an arm. On demobilization in 1919 he obtained the appointment of anaesthetist at the Throat and Ear Hospital in Golden Square, and also to the Queen's Hospital for Plastic Surgery at Sidcup. Then in 1922 he was appointed anaesthetist to St. Mary's, where for some years he had a close association with the late Mr. Clayton Greene—a sufficient testimony to the trust and esteem in which his professional capacity was held. Another was his election to the office of president of the Section of Anaesthetics at the Royal Society of Medicine during this war. Although he had command of the newer appliances and used them with skill, he never forgot the obligation he owed to the students whom he had to teach and that often they would have to rely upon simple methods, for elaborate apparatus would not always be available in practice. He insisted, therefore, upon simplicity in anaesthesia when it was possible without sacrificing other advantages, and his point of view was appreciated alike by surgeons and students. This simplicity was truly part of his character, and with unfailing kindness endeared him to the many with whom he worked for so long.

Major C. E. S. Phillips, whose death occurred on June 17, was born in February, 1871. Charles Phillips was a gifted man; he played the violin, painted in oils, and was otherwise dexterous of hand. Easy financial circumstances all his life allowed him to put his time at the service of science in many ways. Perhaps his most important piece of applied science was done on the War Office *X*-ray Committee during the last war. The question of portable *x*-ray equipment for work in casualty clearing stations on a big scale had certainly not been solved in 1914, and the committee tackled the problem under the joint leadership of Prof. Callendar and Sir Archibald Reid, the organization of the laboratory work being in the hands of Dr. J. H. Brinkworth. Phillips also prepared a kind of non-transparent glass which had unusual electrical conducting power, and physicists in the early years of radio-activity struggling with electroscopes which had to be frequently charged were grateful to him for a very ingenious electrical charger. Phillips gave freely of his time in the service of scientific societies, at whose meetings his genial ways won him many friends. He was at one time president of the Röntgen Society and acted as honorary treasurer over a period of many years for that society, the Institute of Physics, and the Royal Institution. He acted for some years as honorary physicist to the Cancer Hospital.

Dr. Arthur George Troup, D.P.H., who had been medical superintendent of the Willesden Municipal Hospital for nearly 20 years, died suddenly at Stonebridge, N.W.10, on July 6. He was born in Aberdeen on Oct. 24, 1884, and was educated at the Robert Gordon College and the University of Aberdeen, where he graduated M.B., Ch.B. in 1906 and proceeded M.D. in 1914. Before his appointment to Willesden in 1925 Dr. Troup had been assistant M.O.H. for Essex and Hampshire, and house-physician and later resident pathologist at the Stephen Ralli Memorial Laboratory, Royal Sussex County Hospital, Brighton. During the last war he served with the R.A.M.C. over-seas as M.O. to the 1/11 London Regiment, to No. 77 Casualty Clearing Station, and to No. 11 Egyptian Stationary Hospital, reaching the rank of acting major. Dr. Troup had received a B.M.A. scientific grant in 1908, was chairman of the Willesden Division in 1931–2, and clinical secretary 1933–4. He was a Fellow of the Society of Medical Officers of Health, had been assistant examiner for the D.P.H. of the English Conjoint Board, and for some years lectured on infectious diseases at the Middlesex Hospital Medical School. He had contributed to the *Journal of State Medicine* and the *Lancet*, and was joint author with Dr. R. Adam and Prof. S. P. Bedson of the report of an outbreak of psittacosis at the London Zoological Gardens published in this *Journal* in January, 1939.

Dr. Francis Darlow, who had been in practice at Horsforth, near Leeds, for 47 years, died on July 8. He was born on March 15, 1872, at Bradford, and from Bingley Grammar School went to the Leeds Medical School. He graduated M.B., Ch.B. of the Victoria University in 1897 and took the same degree *ad eundem* at Leeds University in 1905. Starting as junior officer in the 1st West Riding Field Ambulance (T.F.) on its formation in 1908 he was transferred to the unit then known as the 49th Division Casualty Clearing Station, with which he went over-seas in 1914. He served with the rank of lieut.-colonel as officer commanding No. 7 C.C.S., and afterwards commanded the 49th (2nd Northern) C.C.S.; he was awarded the Territorial Decoration and retired as colonel. Dr. Darlow had been a member of the B.M.A. since graduation. He was an associate of the Yorkshire College and a member of the Leeds and West Riding Medico-Chirurgical Society. He took a keen interest in the British Legion, and for a number of years was a member of the Horsforth Urban District Council.

The death is announced of Mr. W. J. Allkins, who was on the editorial staff of the *Medical Directory* for 46 years. Joining the firm of J. and A. Churchill at the age of 17, he retired in 1933. Owing to the absence of the editor and subeditor on active service, he took up his duties again in 1941 and was acting editor during the centenary year of 1944. His quiet efficiency and strict attention to detail contributed much to the accuracy and usefulness of this well-known work of reference.

Universities and Colleges

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—G. Caplan, F. S. Hawkins, J. A. Herd.

FINAL M.B., CH.B.—*†H. Jackson, *‡ M. H. Oelbaum, *‡ N. J. Roussak, Constance Atkinson, N. J. Blockey, J. L. Braithwaite, M. Brookes, R. B. Broughton, Dorothy B. Charlton, N. K. Crooke, ‡J. F. Dark, B. H. Dawson, A. Dowling, J. E. Drabble, C. L. Dubberley, Lucy M. Dunkerley, Mary E. Eagles, R. B. Fitzgerald, G. C. Fletcher, L. Freedman, R. L. Gadd, Margaret Hedley, F. Howarth, E. C. Hutchinson, F. B. Jackson, N. A. Law, Kathleen V. Lodge, K. Lowe, E. V. Mellor, T. Mooney, Kathleen, P. E. Mumford, †‡Sylvia N. Nabarro, H. Nussbaum, A. O. Osbaldeston, M. C. Pennington, ‡ A. H. C. Ratcliff, A. H. Rowson, M. H. Russell, E. P. Samuel, J. P. Smith, Margaret E. Tate, H. S. Trafford, J. G. Vause, A. G. Walker, Marie R. West, Alice R. E. Widdows, J. D. Willins, J. Wiseman, E. Wood. *Part I.—Forensic Medicine and Hygiene and Preventive Medicine:* Margaret E. Bailey, J. I. Bentley, P. Brooks, R. H. Broughton, W. B. Browne, B. N. Catchpole, D. A. Chadwick, C. P. Chivers, J. F. Cogan, H. S. Coulsting, J. K. Craig, Annie Cross, K. S. Daber, Elsie M. Dakin, A. M. Davies, Vera A. Dearden, O. G. Dodge, Jean B. Fletcher, C. J. Glancy, I. M. Gow, P. W. Harvey, A. B. Haward, H. G. Herrman, H. P. Hilditch, C. B. Hindley, D. A. N. Hoyte, E. V. Hulse, J. A. Jamieson, Elizabeth Jenkins. P. D. Kelsall, P. B. Lacy, B. H. Lees, T. K. J. Leese, E. Levy, E. S. Lomas, D. Longson, J. D. Lumsden, S. T. Lunt, Winifred M. McIlwrick, D. A. MacLeod, J. Marshall, Jessie Million, N. S. Moores, J. Needoff, M. Panikkar, I. W. Payne, N. W. Preston, E. Priestley, D. W. Purser, Aune R. Quinn, Kathleen Rampling, Margaret Rhodes, R. G. Rooney, K. A. Rowley, V. E. Sherburn, K. D. Stewart, Roberta A. Stewart, J. B. L. Taylor, Hilary M. Thompson, H. S. Trafford, F. N. Valdez, J. G. Vause, Lorinda Wallace.

* Awarded second-class honours. † Distinction in Medicine. ‡ Distinction in Surgery.

UNIVERSITY OF DURHAM

The honorary degree of D.Sc. of Durham University was conferred on July 11, at King's College, Newcastle, upon Sir Alexander Fleming, F.R.S., F.R.C.P., F.R.C.S., professor of bacteriology in the University of London, and director of the department of systematic bacteriology at St. Mary's Hospital Medical School.

UNIVERSITY OF EDINBURGH

At a graduation ceremony held on July 11 the following degrees were conferred:

M.D.—[1]J. F. Curr, [1] [2]Major R. B. Lucas, R.A.M.C., [2]Major A. Roberts R.A.M.C., R. V. Thomas, Surg.-Cmdr. D. C. Wilson, R.N.V.R.

D.PHIL.—[2]S. K. Basu, M.B.

M.B., CH.B.—J. D. Abbatt, Barbara M. Adams, R. N. Andrew, T. B. Anthony, A. D. Bain, W. L. Barton, A. D. R. Batchelor, S. H. B. Blaikie, Margaret H. G. Borrowman, M. Brown, A. D. Caird, Margaret A. Calder, Elspeth, S. K. Campbell, Mercédès D. Carvel, A. F. Catto, Gwen S. Clark, Lorna H. Cortis-Stanford, L. F. G. Cruickshank, A. Davies, Anne D. G. Davies, E. C. K. Douglas, G. K. Douglas, K. M. Douglas, Marie-Hélène D. Douglas, Helen N. Duke, D. Durie, Frances B. Early, D. J. Ellison, [3]Constance C. Forsyth, A. H. Fraser, F. C. Fraser, Doreen C. Gardner, D. F. Gibbs, E. Gilderdale, W. J. Gillies, J. C. Gould, J. T. Gray, Agnes I. Greig, N. D. Gunasekara, A. I. Gunn-Russell, [3]Hilary F. H. Hamilton, I. R. Henderson, E. B. Hendry, L. W. Hereward, C. Hyman, H. Innes, A. W. Irons, J. W. Jackson, W. C. Jamieson, Evelyn I. C. Jardine, G. P. Jeffrey, T. Joyce, J. Kirk, A. B. G. Laing, I. Lindsay, R. Ll. Lyon, Mary M'Donald, A. MacFarlane, Mary L. Macfarlane, G. M'L. M'Gillivray, J. M'Inally, A. B. M'Intosh, W. G. M'Intosh, D. G. Mackay, G. L. Mackay, J. R. G. Mackessack, Janet L. M'Laren, Margaret E. Macnair (*née* Cameron), R. S. M'William, A. Mather, Alison M. Matheson, J. D. Matthews, Nina A. Mellon, W. G. Merriman, Mary Y. I. Millar, Isobel L. Morrison, Margaret Munro, Isobel J. Murray, A. B. Ostrovsky, Katherine S. H. Pattullo (*née* M'Connell), J. M. U. Philip, [3]T. P. S. Powell, W. D. Rider, Jean A. Ritchie (*née* Wilson), W. A. T. Robb, M. Segal, D. Simpson, H. M. Sinclair, [3]I. S. R. Sinclair, Elizabeth B. Smith, A. R. Souyave, R. F. H. Spencer, W. J. Stedman, D. D. Stein, N. L. Stokoe, A. A. B. Swan, G. S. Taylor, Margaret H. F. Turnbull, I. A. Waldie, J. R. Walls, H. Watson, Josephine A. C. Weatherall (*née* Ogston), G. G. Wells, Beatrice M. Wilson.

[1]Commended for thesis. [2]*In absentia.* [3]With honours.

Degrees were also conferred by the Polish School of Medicine at Edinburgh.

The following prizes, etc., were presented:

Cameron Prizes in Practical Therapeutics: Sir Alexander Fleming, F.R.S., and Sir Howard W. Florey, F.R.S. *Ettles Scholarship and Leslie Medal, Buchanan Scholarship in Midwifery and Gynaecology, Royal Victoria Hospital Tuberculosis Trust Medal:* R. F. Robertson. *Scottish Association for Medical Education of Women Prize, Dorothy Gilfillan Memorial Prize, Keith Memorial Prize in Systematic Surgery, Murchison Memorial Scholarship in Clinical Medicine, Pattison Prize in Clinical Surgery:* Hilary F. H. Hamilton. *Mouat Scholarship in the Practice of Physics:* J. S. Robson. *James Scott Scholarship in Midwifery and Gynaecology:* A. D. Bethune. *Beaney Prize in Anatomy and Surgery:* I. S. R. Sinclair. *Annandale Medal in Clinical Surgery:* G. L. Mackay. *Murdoch Brown Medal in Clinical Medicine:* T. P. S. Powell. *Wightman Prize in Clinical Medicine:* W. A. T. Robb. *Lewis Cameron Postgraduate Prize:* G. Dempster. *Lewis Cameron Undergraduate Prize in Bacteriology:* H. A. F. Dudley. *Colonel Thomas Biggam Memorial Medal and Prize in Pathology:* Eileen V. M'William. *Maclagan Prize in Forensic Medicine:* J. Brown (Faculty of Medicine) and D. F. Macdonald (Faculty of Law). *Anderson Henry Prize in Botany:* S. F. Hayes and N. R. W. Taylor (equal). *Cunningham Memorial Medal and Prize in Anatomy:* J. Richmond; *prox. acc.*, J. L. Rennie. *Whiteside Bruce Bursary and Vans Dunlop Prize in Physics and Chemistry:* W. F. Coulson. *Vans Dunlop Prize in Botany and Zoology:* P. G. Aungle; *prox. acc.*, Constance M. Whitfield.

UNIVERSITY OF GLASGOW

At a ceremony of graduation, held on July 11, the following medical and surgical degrees were conferred:

M.D.—*A. Brown, †T. Semple.

CH.M.—*W. M. Borthwick.

M.B., CH.B.—‡Agnes W. Brown, †R. Fife, †J. T. Naismith, †Agnes S. Conway, †W. F. M. Fulton, †H. B. W. Greig, †A. C. Kennedy, †J. Stewart, Muriel S. Alexander, C. K. Allan, G. C. Arneil, K. W. Medical News

The annual general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., on Saturday, July 28, at 2.30 p.m., when there will be a discussion on "The Optimum Methods of Treatment of Venereal Diseases by Penicillin," to be opened by Col. D. M. Pillsbury, U.S. Army, and Major J. Marshall, R.A.M.C.

Col. Walter Elliot, Miss Florence Horsbrugh, and Sir John Boyd Orr are among the visiting speakers who will address students attending the residential summer school which is to be run at St. Andrews University by the Scottish Council for Health Education from Aug. 18 to Sept. 1, with the general theme of "Teaching the Young How to Live." Courses in physiology, psychology, and social medicine have been prepared. This summer school in health education is the first full-scale venture of its kind to be held in Scotland. Full particulars may be had from the secretary, Scottish Council for Health Education, 3, Castle Street, Edinburgh, 2.

The annual luncheon of the Society of Medical Officers of Health will be held at the Holborn Restaurant on Friday, Sept. 21, at 12.30 for 1 p.m. The President (Prof. R. M. F. Picken) will take the chair, and he will be supported by a number of distinguished guests. As the attendance must be limited to 150, members of the society are asked to make early application for tickets, which will be allotted according to priority. Those who wish to bring private guests will receive notice later if seats will be available. The tickets (10s. 6d. including gratuities, but not wine) are obtainable from the acting executive secretary, Society of Medical Officers of Health, Tavistock House South, Tavistock Square, London, W.C.1. A meeting of the society's Council will be held before the luncheon on Sept. 21.

The Council of the Association of Anaesthetists of Great Britain and Ireland entertained Capt. and the Hon. Mrs. Leslie Gamage to lunch on July 5, when the president thanked them warmly for their gift of a Grant of Arms for the Association.

At a meeting of the court of governors of the Middlesex Hospital on July 11, the chairman, Col. J. J. Astor, announced that it was hoped that bicentenary celebrations might be held in July, 1946. The occasion should have been celebrated this year, but when arrangements were being discussed the flying bombs and rockets began to fall and the matter had to be deferred.

The Middlesex County Council has decided that the Staines County Hospital shall be known in future as the Ashford County Hospital, Middlesex, to avoid confusion with the neighbouring Staines Hospital.

In the recent Northern Ireland General Election Dr. G. Dougan (U.) was re-elected to the Northern Ireland House of Commons as the member for Central Armagh, and Dr. F. McSorley (Ind.) was elected as one of the representatives of Queen's University, Belfast.

Dr. David Adler, a well-known Brazilian plastic surgeon, has arrived in this country for a six-months visit, arranged by the British Council. Dr. Adler, who graduated in 1933 from the Faculty of Medicine, University of Rio de Janeiro, is the consulting plastic surgeon to the Air Force Hospital at Rio de Janeiro. During his visit here he will meet, and work with, British plastic surgeons—among them Sir Harold Gillies.

A meeting of the Medical Society of the L.C.C. Service will be held at Southern Hospital, Dartford, on Thursday, Aug. 2, at 2.30 p.m., and will be devoted to rehabilitation and clinical demonstrations.

Two inevitably belated reports on the health of the island in 1940 and 1941 from Dr. Rowan W. Revell, M.O.H., Guernsey, have reached this office. The sanitation in the island is regarded as being most unsatisfactory, with gross overcrowding taxing the sanitary accommodation far beyond its capacity. A general lowering of health was noted, also the widespread occurrence of certain deficiency diseases. Furunculosis and other septic infections were prevalent, probably due to vitamin A deficiency. Neuritis and degenerative changes in the nails were common and were often cured by vitamin B. The population of 23,901 had a death rate of 14.6 per 1,000 in 1940 and 16 per 1,000 the following year. There was little infectious disease in Guernsey.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* measles notifications fell by 622, and those for whooping-cough and acute pneumonia rose by 77 and 48 respectively.

The rise in whooping-cough was general throughout the country except in the east and south-west. The increase in acute pneumonia occurred mainly in Yorkshire and the south-west. The largest local variations in notifications of diphtheria were increases of 10 in Essex and in Yorks West Riding, and a fall of 18 in Durham. Measles was less prevalent almost everywhere. Southampton had 149 fewer cases, and Kent 128.

Dysentery notifications went up by 5. The largest returns were Lancashire 60, London 33, Nottinghamshire 27, Kent 17, Northumberland 15, Yorks West Riding 14, Somerset 13.

In *Scotland* falls were recorded in the notifications of infectious diseases as follows: measles 244, dysentery 39, scarlet fever 21, diphtheria 17. The totals for dysentery and diphtheria were the lowest in recent months.

In *Eire* the total of 55 for diarrhoea anad enteritis was the largest since the beginning of last year: 47 of the cases were notified in Dublin C.B.

Northern Ireland reported an increase of 11 in the notifications of whooping-cough.

Food-poisoning

One fatal case of food-poisoning from meat has been reported from Blackpool, and 3 fatal cases from Stoke-on-Trent. The latter outbreak, which has caused the serious illness of other persons, was traced to a cooked-meat shop at Longton. The food had been contaminated by mice and snails.

Vital Statistics for the First Six Months of 1945

The notifications of diphtheria in England and Wales during the first twenty-six weeks were the lowest yet recorded, but the notifications of dysentery were very high. The total for measles was the largest since notification began. The figures for the first half-year are:

	1940	1941	1942	1943	1944	1945
Scarlet fever	25,224	29,517	29,527	50,544	48,654	36,302
Whooping-cough ..	15,642	99,748	36,616	50,302	56,488	33,587
Diphtheria	18,221	26,147	20,569	19,154	15,978	12,032
Measles	137,718	363,307	100,497	347,687	52,622	412,823
Acute pneumonia ..	32,676	32,899	27,369	28,442	24,499	21,472
Cerebrospinal fever ..	9,193	7,767	4,271	2,203	1,851	1,691
Dysentery	1,085	3,167	3,400	3,002	5,669	10,006
Paratyphoid and typhoid	998	1,169	442	358	247	259

The returns for the great towns suggest that the death rate and infant mortality will exceed the rates for 1944, when infant mortality was the lowest ever recorded. There have been fewer live births. The returns are:

	Great Towns, first 26 weeks			
	1942	1943	1944	1945
Deaths	129,230	124,090	128,656	132,693
Live births	150,858	169,956	186,651	174,276
Infant mortality ..	62·6	59·5	54·0	58·5.

Week Ending July 7

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,312, whooping-cough 1,050, diphtheria 458, measles, 4,544, acute pneumonia 352, cerebrospinal fever 51, dysentery 210, paratyphoid 6, typhoid 11, poliomyelitis 15.

No. 26

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 30.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

Rate per 1,000 total births (including stillborn)			24					32		

---

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

X Rays and Prostatic Hypertrophy

Q.—*Is there any evidence that the treatment of commencing prostatic hypertrophy by deep x rays, before total obstruction has occurred, has given either temporary or permanent benefit?*

A.—There is no evidence that either the symptoms or the gross pathological anatomy associated with benign prostatic hypertrophy is influenced by deep *x*-ray treatment.

Prolapsus Ani in a Child

Q.—*A child of 3 years has prolapsus ani. The prolapse, which does not occur every time the child has a stool, is, of course, of mucous membrane only, and is quite easily replaced. It is not increasing in size. There is no phimosis or anything to cause straining at stool. (1) What is the best treatment? (2) Up to what age can a natural cure be expected? (3) In what percentage of cases does a natural cure fail to occur?*

A.—There are certain points to realize about this condition.

1. It is not dangerous to life. I can find no case of a death due to it occurring at the Hospital for Sick Children, Great Ormond Street, in the last quarter of a century.

2. It is not painful. This is obvious to anyone who watches a child while the bowel is down.

3. It is, in the great majority of cases, an accomplishment rather than a disability. Anyone who has endeavoured to study the condition finds that when a child is admitted to hospital the prolapse almost invariably fails to occur, in spite of active exercise being permitted. When, however, the child finds the disciplinary gaze of the ward sister has changed to a worried and expectant home circle he once more takes the opportunity to become the centre of attention.

4. There is a strong tendency to spontaneous cure if the condition is treated with the minimum of notice.

5. It is often made worse by injudicious treatment.

6. It is associated much more with frequency of the bowels than with constipation.

No treatment of the efficiency of, for instance, Hamilton Russell's operation for inguinal hernia, is known. Below are listed most of the usual methods with comments.

1. *Administration of Paraffin, Other Purgatives, and Enemas.*—This common line of treatment comes from the idea that the prolapse is due to straining to pass a hard stool. This is not so; it is much more due to straining with an empty rectum; and such treatment only makes it worse

2. *Strapping the Buttocks Together.*—As a motion cannot be passed when the buttocks are strapped, and as the prolapse occurs only after the passage of a motion, I have never understood the reasoning behind this treatment. It is quite futile.

3. *Passing the Motions Lying Down.*—When the child can be persuaded to do this it is the best treatment of all, and almost invariably stops the prolapse occurring and allows the sphincter to recover normal tone. It is best done by placing the child on a piece of waterproof sheeting arranged at a slight slope. Usually, however, the relations between mother and child are not such as to permit of this.

4. *Linear Cauterization of the Mucosa.*—I have no experience of this, and the risks of disaster in going too deep in the thin bowel of a child are obvious.

5. *Peri-rectal Injections of Various Substances.*—These are given with the idea of promoting adhesions between the bowel-wall and the walls of the pelvis. Absolute alcohol is used, but 5% carbolic in olive oil is probably better, about 3 c.cm. being injected just outside the bowel wall laterally and posteriorly, the position of the needle being controlled by a finger in the rectum.

6. *Peri-anal Suture.*—This is probably the most reliable surgical treatment. A ring of No. 1 catgut (Ombrédanne, in the French fashion, used silver wire) is run round the anus in the external sphincter and tied round an assistant's finger, which gives a suitable diameter.

(It should be noted that in all these last three methods of treatment it is not easy to dissociate mechanical effects from those produced by making the process of prolapse moderately painful. An instructive experience was when, in a most obstinate case, a peri-anal suture was half inserted and then removed because of fouling of the area during operation. The result was a prompt and permanent cure.)

7. *Resection of the Prolapsed Bowel.*—I mention this as a curiosity of treatment which could occur only in the present stage of surgical practice. The result of the single case in which I have known it performed in a child was an intractable stenosis and a colostomy.

Bronzing under Sun-lamps

Q.—*Why is it that natural sunshine causes bronzing of the skin, while exposure to an ultra-violet lamp at home causes redness, peeling, and no bronzing?*

A.—It would not be correct to say that artificially produced ultra-violet rays cause redness and peeling but no bronzing. For ultra-violet radiations from the carbon-arc lamp are very similar in wave-length to those from the solar spectrum and can produce deep pigmentation of the skin. The question probably arises from the use of a quartz mercury-vapour burner, which produces more of the shorter ultra-violet rays. These readily cause erythema and peeling but do not cause deposition of pigment in the skin to the same extent as the longer rays. But repeated exposure to the rays from a mercury-vapour lamp can, nevertheless, produce pigmentation, though not to the same extent as exposure to the solar rays.

"Talbot's Iodine"

Q.—*What is the formula of a prescription used in the treatment of pyorrhoeic gums and called "Talbot's iodine"?*

A.—The formula for "Talbot's iodine" is: zinc iodide 15, water 10, iodine 25, and glycerin 50 parts.

Continued Frequency after Gonorrhoea

Q.—*Twenty years ago a patient had treatment for gonorrhoea, and after having been pronounced cured he married and produced 4 children. Three things he has never been free of since his cure are: (1) frequency and urgency of micturition, (2) nocturnal erections, relieved by passing water, and (3) soreness of the glans unless he washes it at least once a day; these are now no better and no worse than they were 20 years ago. For an almost microscopic amount of non-specific urethral discharge diuretics, sulphapyridine, and sulphathiazole have been tried without avail; would penicillin help? What this man complains of most is frequency ("Must my life be punctuated by urinals?"). Can anything be done for him?*

A.—One thing seems to be reasonably clear—that the patient was cured of his gonorrhoea. The frequency and urgency of micturition and the nocturnal erections quite possibly may be due to a residual non-gonococcal prostato-vesiculitis or to an enlarged prostate. A digital examination of the prostate and seminal vesicles and microscopical and cultural examinations of the expressed secretions are indicated. The soreness of the glans penis would not appear to be due to the same cause; in any case it is customary to wash the glans daily as a simple hygienic measure. Infestation with *Trichomonas vaginalis* should not be forgotten, and might account for all the symptoms; there is reason to believe that this condition is commoner than has been supposed hitherto. Another possible explanation is oxaluria. The diagnosis and exclusion of these are obvious.

Treatment will depend on diagnosis; the blind use of penicillin would be most unscientific; this antibiotic is indicated only when infection with a penicillin-sensitive organism is proved.

Pregnancy after Subtotal Hysterectomy

Q.—*A patient, aged about 37, had a subtotal hysterectomy for excessive menstrual bleeding which did not respond to hormone therapy or dilatation and curettage. Since then she has been well, and is now getting married. Is there any risk of pregnancy? The question may look foolish, but I presume it is possible that the proximal end of one or both tubes may canalize, and, supposing they were anywhere near the cervical stump, an ovum might escape. I seem to remember reading of a cervical pregnancy after a subtotal hysterectomy, though this must be a freak occurrence.*

A.—Pregnancy can occur after subtotal hysterectomy and may develop in the cervix, tube, or adjacent tissues. It is, however, extremely rare, and according to D. A. Connors and others (*Amer. J. Obstet. Gynec.*, 1943, **45**, 309) only six cases had been reported up to 1943. A seventh was described in November, 1944, by Margaret Stanley-Brown and Frances E. Shields (*Amer. J. Obstet. Gynec.*, 1944, **48**, 714), and there have also been a few reports of cases of doubtful authenticity. In Connors' case the cervix dilated and a premature baby weighing 896 grammes was delivered through the vagina and lived 33 hours. The pregnancy was said to have been tubal in site, but W. E. Studdiford (*Amer. J. Obstet. Gynec.*. 1945, **49**, 169), in reviewing this case, suggests that it was more likely to have been a cervical pregnancy.

In nearly every case described the divided ends of one or both tubes had been sutured to the cervical stump, so communication between the cervix and tube was the more easily established. In one case, however, both tubes and one ovary, in addition to the uterus, were removed, and the pregnancy occurred as a result of direct contact between the remaining ovary and the cervix. These rare instances, although of academic interest, should certainly be regarded as freaks, and the chances of any woman's becoming pregnant after subtotal hysterectomy are so remote as to be outside practical consideration.

Sodium Bismuthyl Tartrate for Arthritis

Q.—*Would any toxic effects be noted after the treatment of arthritis of many joints of two years' duration in a woman of 62, by injections of sodium bismuthyl tartrate?*

A.—In the writer's experience no toxic effects have followed the treatment of arthritis by injections of sodium bismuthyl tartrate, beyond a slight sense of fatigue and temporary increase of stiffness. A slight local reaction in the shape of tenderness round the site of the injection is often felt, but soon clears up. The initial dose should not exceed one grain, and in a patient of the age mentioned any further increase might be undesirable and the interval between doses should not be less than a fortnight and may be gradually increased to a month or six weeks.

Bleaching for Hirsutism

Q.—*Can you describe the best method of bleaching for a case of mild hirsutism? Peroxide and ammonia do not seem to be effective, but the method employed may be at fault.*

A.—The method described is usually an effective bleaching procedure; it is assumed that the solution has not been allowed to deteriorate by being kept too long before it is used.

"Trigger Finger" and "Snap Finger"

Q.—*What are the cause, pathology, and treatment of "trigger finger" and "snap finger"?*

A.—"Trigger finger," "snap finger," and "spring finger" are names given to that condition in which one of the fingers, commonly the right middle finger, cannot be fully extended until by special exertion or by external aid full extension is produced with a jerk which is sometimes accompanied by an audible snap or click. It is more often found in women. The condition results from a slight swelling of one of the flexor tendons which finds difficulty in passing through a relative narrowing of the fibrous tendon sheath. Rarely the condition is congenital. The acquired form may follow healing of a punctured wound of the tendon sheath; or it may result from subacute inflammation stated in some cases to be due to repeated external pressure over the affected site occurring in the course of the patient's occupation. Occasionally it may occur as the result of a small tumour of the tendon or tendon sheath. I cannot confirm the statement that rheumatism may be a causative factor.

A few cases are said to right themselves after a time. Mild cases due to indirect trauma may sometimes be cured by complete rest of the tendon, which can be procured only by adequate splinting for some weeks. In those cases in which palliative treatment does not cure and the patient experiences serious disability one must advise exploration of the tendon sheath. This operation must be carried out only by a competent surgeon with rigidly aseptic technique. The lesion is generally at the level of the metacarpo-phalangeal joint. Any small and localized lesion of the tendon should be removed; if there be a spindle-shaped enlargement of the tendon, it may be possible to reduce it to normal size by excising a narrow longitudinal strip. If this is considered inadvisable it may be sufficient to provide more room by omitting to suture the incision made into the fibrous sheath at the narrowed site; this will allow sufficient play for the tendon to move easily.

Nocturnal Cramp in the Elderly

Q.—*Can you suggest treatment for nocturnal cramp in a female patient aged 77? The attacks come on fairly regularly in the calves of both legs at about 3 a.m. General health and condition is excellent. Urine, blood pressure, arterial wall, etc., seem normal. Diet makes no difference.*

A.—Nocturnal cramp in the elderly is a mysterious phenomenon and the mechanism appears to be unexplained. It is obviously different from intermittent claudication, though similar treatments are often recommended. There is need for a controlled trial of remedies, as it is hardly credible that all those suggested are effective. In answers to similar questions on March 13 and 27, 1943, warm leg baths twice daily, particularly before retiring at night, nicotinic acid 50 mg. daily, and resting with the feet up were recommended. Dr. Lionel Picton suggested that calomel gr. 1/10 at night was a sovereign remedy, while others have praised copper sulphate gr. 1/10 to 1/6. Another line of treatment is to increase the fluid intake, giving a tumblerful of water half an hour before each meal and again before going to bed. Short courses of iodide of potassium have been recommended on theoretical grounds. Quinine and alcohol might be expected to be effective, but the former is now reserved for malaria, and the latter is almost as difficult to obtain.

D.D.T. for Pediculosis

Q.—*Can D.D.T. powder be applied neat in the treatment of human pediculosis? If not, what is the best easily available solvent?*

A.—D.D.T. is most easily used for pediculosis corporis in the form of a powder diluted to 10% in any inert dust. It should *not* be applied to the body in the form of a solution, as it is considerably more toxic to mammals in solution than when in crystal form. (See the annotation on toxicology of D.D.T. in this *Journal*, March 10, 1945, p. 338.)

Pregnancy after Amoebic Liver Abscess

Q.—*A woman aged 25 and two months pregnant was in July, 1944, severely ill with a liver abscess, which was opened and drained. About a gallon of pus was removed and was found to be due to the Entamoeba histolytica. She now appears to be in fairly good health. Is there any indication that the pregnancy should be terminated? She has had one normal confinement 5½ years ago, and while incubating her amoebic dysentery gave birth to a six-months anencephalic foetus.*

A.—Pregnancy in itself, after an amoebic liver abscess, cannot be regarded as inimical to the health of the individual. In this particular case, however, the liver abscess appears to have been very large, and the patient became severely debilitated during its course. The assessment of her condition and her fitness to continue pregnancy can be made only on general grounds; the mere previous existence of an amoebic liver abscess is not in itself a contraindication to pregnancy.

Injury from Mine Explosion

Q.—*A naval officer, in a ship blown up by a mine, was thrown into the air and landed back on his feet, sustaining severe impacted, comminuted fractures of the upper ends of both tibiae. The lower ends of the femora were undamaged. The question arose whether the damage to his tibiae was done by the explosion acting upwards through his legs, or from his body weight acting downwards when he landed. I believe the naval conception is that it is the upward thrust of the explosion which causes the damage, but to me this is strange, as, in spite of the upper end of the tibia being weaker, it would be the moving bone, and I would expect to see at least some damage to the lower end of the femur on the x-ray films.*

A.—The questioner seems to attach considerable importance to the undamaged condition of the lower ends of the femora. Presumably they were not inspected, and the absence of any evidence of damage in the *x*-ray film is evidence only of damage *re* the bone. One might cite a comparable injury—namely, fracture of the upper end of the radius. These are much more frequently treated by open operation within ten days of the injury, and I should have said that there is always some damage to the capitellum of the humerus when inspected, although the *x*-ray picture shows often no injury to the bone. The cartilage of the capitellum may be extensively compressed and injured severely.

On statistics, this officer should have fractured his os calcis rather than the upper ends of the tibiae. We must have seen dozens of fractured os calces from mine explosions under the ship or explosions between decks, when the deck comes up and strikes the patient above. The force of the explosion is terrific, and may easily be enough to throw a man some feet into the air. Several men have come down in the water with their fractured os calces, but an hour or two in the water, even swimming, does not seem to do any harm to the fractures. The force of the deck coming up against the patient must be very much greater, when measured in pounds to the square inch, than any force exerted by a patient falling from a height.

It is unusual for the upper end of the tibiae to give way in preference to the os calcis, but here one would point out that the os calcis is the moving bone, as the questioner puts it, but it is the bone that gives way. It might be that this officer was standing with his knees a bit flexed, so that the force of the tibia being driven upward drove the tuberosity against a more convex portion of the femoral condyle. This patient might have dislocated his hip or fractured his spine if these two latter had been in flexed positions

I can recall one bar-tender, who was standing on the floor with her elbows on the bar when a bomb exploded in the basement Both her os calces and her elbows were fractured. But I am supposed to deal with this problem from the point of view of a Nava surgeon.

INCOME TAX

Return to United Kingdom

J. B. resigned his appointment with a foreign Government and returned to the United Kingdom on April 25, 1945. His salary continued until the end of June when his appointment terminated. During his service abroad he paid 5% of his salary into an "Indemnity Fund," to which his employers paid equal amounts and the total amount accumulated will now be paid to him.

⁂ (*a*) J. B. is a British resident from 1945–6, and that portion of his salary which is paid to him in this country is liable to income tax—including, we think, the 5% deduction which reaches him through the Indemnity Fund. (*b*) The lump sum paid to him out of the Indemnity Fund does not appear to rank as "income" liable to assessment.

Preparation of Balance Sheets

J. M. has for many years had a complete balance sheet prepared for the Inland Revenue by his accountant—including the value of his furniture, etc. Ought his wife's furniture and jewellery to be included also?

⁂ A balance sheet prepared in connexion with a trade or profession does not ordinarily include assets which are not owned by the proprietor and used in the trade, etc. We see no reason why furniture, etc., belonging to J. M.'s wife should be included in a balance sheet prepared in connexion with his professional practice.

Cost of Maid's Board and Lodging

J. K. has for the past fifteen years been allowed a deduction of 1/3rd of £52 a year as representing the appropriate part of the cost of the domestic service employed on the professional part of the premises. His accountant has claimed an increase of the deduction to 1/3rd of £104, but the inspector of taxes has refused to admit that claim.

⁂ In this kind of claim so much depends on the actual facts of the case—wages paid, and cost of food, rent, etc.—that any general guidance is apt to prove dangerous. But a total charge of 6s. 8d. a week certainly appears to be very low nowadays. We suggest that in the first place careful estimates be made (*a*) of the total cost of the maid, including a proportion of rent, rates, and general expenses as well as of food and wages, and (*b*) of the proportion of her time spent on the professional side of the work. If, as seems likely, the figures point to an allowance materially in excess of 6s. 8d. per week, the claim should be pressed, and taken to general appeal if further discussion with the inspector proves fruitless.

Division of Partnership Liability

"E.M.S."—A and B. are in partnership. "B. is serving in the E.M.S. and his salary is included in the partnership assessment. Since April, 1944, tax has been deducted from his salary under P.A.Y.E." How should the liability be adjusted between the partners?

⁂ We suggest that in the first place the assessment on the partnership under Schedule D be reduced by excluding the E.M.S. salary—i.e., by the amount which has been included in the gross receipts. The firm's total liability will then be £x (assessed under Schedule D) plus £y (assessed on B. on the amount of his earnings for the current year). The aggregate sum (£x+ £y) should then be divided according to the partnership shares and each partner's share of the tax calculated on that basis. No doubt the inspector of taxes will assist if requested.

Change from Civilian Earnings to Army Pay

F. H. joined the Army in September, 1942. In 1941–2 he was a student and his earnings for that year were small. Can he claim to be assessed for his first year in the Army on the previous year's basis?

⁂ No. Where a radical change in employment occurs the subsequent earnings must be assessed on the basis that they are derived from a new source, and in such cases the first subsequent year's earnings are assessable on the basis of the actual year.

War Damage Contributions

J. R. inquires whether these payments are deductible for income-tax purposes, and if not, why not?

⁂ The deduction is forbidden by Section 113 of the War Damage Act, 1943. The reason is understood to be that the Government is pledged to contribute to the fund up to a maximum of the total amount of the contributions, and is not prepared in addition to face the additional financial loss which would result from the income-tax allowance of the individual's contributions. Premiums on policies to provide further insurance cover are allowable.

LETTERS, NOTES, ETC.

"Another Melancholy Example"

Dr. Esther Carling writes: In the small print of "Letters and Answers" in the *Journal* of July 14 (p. 74) is an Editorial comment which deserves the prominence of a general article. It deals with the Government's attitude to the safety of infant lives, describing it in the words at the head of this letter. That American troops in this country should receive a protection from unsafe milk which we do not accord to our own young children is surely a scandal that should be cried aloud.

Vulval and Pubic Boils

Dr. C. McCluskey (Dungannon) writes: Concerning the answer to the question about vulval and pubic boils (July 7, p. 34), surely in such a potentially moist flexural area one could not begin treatment without excluding the auto-inoculation of bacteria by scratching when a yeast is present. The isolation of this, and, if it is present, a benzoic salicylic acid ointment, will quickly resolve the condition.

Physiology and Psychology of Craving

Mr. Eric C. Wood (Chief Chemist, Virol Limited, Ealing, W.5) writes: Dr. H. C. Broadhurst states (July 7, p. 36) that "we have not in fact an instinctive liking for the right *kind* of food," and that "rats deprived of vitamin B possess no instinct which prompts them to select food containing this vitamin when a variety of foods is offered to them." His remarks are doubtless based on the work of L. J. Harris (*Vitamins in Theory and Practice*, 1938, pp. 199–206). But this is not the whole story. Dr. Magnus Pyke in a most interesting and suggestive article (*Nature*, 1944, **154**, 229) quotes the work of Prof. Richter at the Johns Hopkins University School of Medicine, in which rats provided with purified carbohydrate, fat, and protein, together with up to 20 tubes containing the essential mineral salts and vitamins each in a separate solution, chose for themselves a perfect diet, even though most of the solutions had neither taste nor smell. Moreover, when the pancreas, adrenals, or parathyroids were removed from certain animals, they adjusted their diets so as to compensate so far as possible for the consequent alterations in their metabolism. Pyke also quotes (from Richter) two experiments with human subjects. "The first concerns a three and a half year old boy with undiagnosed destruction of the adrenal cortex. This child kept himself alive for more than two years by eating handfuls of salt. When he was taken under control and fed a 'proper' hospital diet he died. The second experiment is of more general application. A graph was made of the percentage of children between the ages of 5 and 14 years who liked a test sample of cod-liver oil. In general the frequency decreased as the age increased and as the known physiological needs diminished." It would seem, therefore, that we cannot afford to be dogmatic on the question under discussion, and there is much need for further research.

Ascaris lumbricoides

Major F. H. Stewart writes: In the *Synopsis of Medicine* by Sir Henry Tidy, under the heading *Ascaris lumbricoides*, the life history of this worm is described and the authority quoted as Low. The work is, of course, mine, published in the *British Medical Journal* and *Parasitology* between the years 1916 and 1921, and confirmed by Ransom and others. Although Dr. George C. Low published several notes of helpful comment on my work in the *Journal* there is no record of research on *Ascaris* by anyone of this name. When this mistake in the 7th edition of the *Synopsis of Medicine* came to my notice I wrote to the author pointing it out and received the following answer: "I am much obliged for your note with regard to the life history of *Ascaris lumbricoides*. I will certainly take it into consideration if I am called upon for another edition." Another edition has been published this year, but the above erroneous statement remains uncorrected.

Sir Henry Tidy writes: Major Stewart is of course quite correct that the credit for this work is due to him. On looking through my correspondence I have found his letter dated Sept. 16, 1939. Matters were somewhat hectic at that time and the letter was placed by mistake in an old folder and was consequently overlooked when the seventh edition was revised. If a further edition is called for the correction will certainly be made. In the meantime I trust that Major Stewart will accept my apologies for the oversight.

Lead Palsy

Dr. W. W. Anderson (London, N.W.11) writes: In your answer in the *Journal* of May 26 on the subject of lead palsy, you say that the extensors of the wrist are affected in painters because those are the muscles "most used." How about my own father, a clergyman, who had a complete palsy the result of chronic lead poisoning caused by drinking water that had been stored in a lead-lined cistern. In his case, at any rate, the cause was not "fatigued muscles."

Hallux Valgus

Mr. W. **Sayle Creer** (Manchester) writes: Your consultant's reply in "Any Questions?" on the prognosis of arthroplasty for hallux valgus in a female aged 65 (June 2, p. 792) is so far from the common experience of a number of orthopaedic surgeons that it ought not to be allowed to pass without comment. Hallux valgus is not "*likely* to be but a part of a widespread foot disturbance" but is *certain* to be. Neither in palliative treatment, such as padding and strapping, nor in surgical treatment, such as an arthroplasty, does the experienced chiropodist or surgeon attempt to correct the disturbance. He sets out to relieve the symptoms which are present. In hallux valgus the symptoms are either pain or inflammation. Pain may be due to pressure of the metatarsal exostosis or an osteophyte which squeezes the skin and other soft tissues against the shoe; to arthritis of the metatarso-phalangeal joint; to incipient or actual ingrown toe-nail caused by the rotation of the hallux; to a callosity under one or more metatarsals; to the overlapping of the first by the second, or vice versa; or to dislocation of the second (rarely another) metatarso-phalangeal joint. Inflammation is due, commonly, to the squeezing of the bursa (bunion) between the metatarsal exostosis and the shoe.

It is quite true that efficiently and regularly applied pads will often relieve the pain due to pressure. But they won't relieve dislocated joints. And corrective strapping corrects for only a few minutes, because poorly shaped shoes quickly nullify its effects. It is a fact beyond dispute that a phalangeal arthroplasty plus an excision of the metatarsal exostosis and trimming of any osteophytes—i.e., reshaping of the metatarsal head—is the quickest and most certain way of relieving the majority of our patients. It is important not to overlook the necessary operation for an established ingrown toe-nail or the dislocation of any other metatarso-phalangeal joint. But it does improve the shape of the foot to an astonishing degree.

If careful tracings of skiagrams taken before and after such an operation are superimposed on one of the theoretical shape which correction of the varus first metatarsal would give, it will be found that the difference is almost negligible. (I would have omitted "almost" if I did not know that as a profession we dislike admitting that we are capable of obtaining excellent results.) In other words, a theoretically unsound operation will generally give a better result than it ought to do. And a theoretically more satisfactory operation is often disastrous. Of course, no patient can start hopping about in a few days. They ought not to be allowed to attempt to walk under three weeks. After another three weeks they will be walking well. After six months they will be singing their surgeon's praises far and wide, and the older ones recover more rapidly than the younger. Naturally—they have had pain for so long.

Local gangrene and delayed healing are not the result of operating on the elderly. They are the result of operating inexpertly. A tourniquet if a general anaesthetic; a small concentration of adrenaline if a local anaesthetic; cutting and not tearing of the tissues; keeping the fingers out of the wound; avoidance of "permanent" deep sutures; not longer than ten minutes per foot; the removal of plenty (almost of excessive amounts) of bone; post-operative rest in plaster-of-Paris for three weeks—there are the secrets of success. Age is of no importance, except that, as already stated, the elderly usually do better than the young. Three weeks in bed and three getting over it are, in the opinion of most patients, much less troublesome than the bother of months of regular visits to the chiropodist. It's over and done with at one go. Lastly, "psychological" treatment is important. Tell the patient the facts of the time it will involve; remember that convalescence is irksome because she is not "sick"; cheer her up; jolly her along; warn her of swelling and aches *before* she complains of them. The pessimistic surgeon commonly gets a bad result.

Ptyalism of Pregnancy

Dr. A. W. **Bauer** (Cambridge) writes: With reference to the question dealing with ptyalism in pregnancy in your issue of April 14 (p. 543) I should like to recommend another remedy: Put repeatedly very thin slices of lemon between the cheeks and the teeth of the patient. This application is not only simple but sensible, inasmuch as it combats the acidosis which in every pregnancy is easily apt to occur unless the diet is kept on basic lines providing the internal metabolism with sufficient indirect alkalis. For those who do not object on grounds of principles to employ homoeopathic remedies, I can suggest two other remedies: Mercurius D4 tablets, one tablet five times a day, or Jaborandi D6 tablets, one tablet three times a day, by mouth. These tablets can be obtained from any homoeopathic pharmacy. I have never refused to employ remedies the efficiency of which has been known to me by experience.

Pregnancy after Perineal Operations

Dr. T. G. **Robinson** (East Boldon, Co. Durham) writes: In the *Journal* of May 5 (p. 652) appears the following question: "A woman of 30, healthy and strong, who was confined a year ago, has just been operated on for cystocele, rectocele, and perineorrhaphy. What advice does one give on future confinements? How soon may she safely conceive, and are there any special precautions? Her only confinement, which took place a year ago, as above mentioned, was a non-instrumental delivery, but she had seven stitches. Before the operation she was fitted with a ring, but even a No. 12 dropped out when she stood up." The answer states, "She should wait at least six months, and preferably one year, from the time of the operation before embarking on another pregnancy." In my view such advice is unduly cautious, and I should be interested to hear the views of others. A properly carried out plastic repair which restores the parts as nearly as possible to normal should stand the stress of labour within a year provided an adequate episiotomy is performed as soon as the head begins to distend the perineum. Last year I operated on a patient whose last period had ended fourteen days previously; she was pregnant, but neither I nor she knew it. In the post-operative period it was noted that the wounds healed unusually rapidly, due, no doubt, to hyperaemia of the parts. The subsequent pregnancy and labour (episiotomy) were without incident. She went home on the sixteenth day of the puerperium and has not developed prolapse or stress incontinence subsequently. I feel that a rule of thumb should not be laid down in these cases. There may have been a few years of infertile marriage before the pregnancy which led to the injuries, and the baby may have been stillborn or died after birth. In such circumstances advice against embarking on another pregnancy may cause psychological upset, which will be accentuated if, after waiting for a year, a pregnancy does not materialize for another year or so. Conversely, if a pregnancy occurs before the "appointed day" distress may be caused to both husband and wife. Lastly I think the wording of the question is unfortunate. Perineorrhaphy is not a condition for which a patient can have an operation. Future advice would surely be given on future pregnancies, not confinements, and a description of the injuries sustained would be preferable to "she had seven stitches."

Sleep-walking

Dr. C. **Ismail** (Ceylon) writes: In the "Any Questions?" column on Jan. 27 last (p. 139) a question was asked as to what precaution could be taken to prevent a girl from sleep-walking. In my limited experience the best and simplest method is to keep a basin of cold water by the side of the bed at the spot where he or she is likely to put the foot down. The moment the bare foot touches the water she will wake up and thus prevent her from sleep-walking. Even if the foot touches the edge of the basin the water will be sprinkled and she will thus wake up.

Allergy to Fish in an Asthmatic

Dr. **Thomas Rees** (Warrington) writes: Mrs. L., aged 55, who is subject to asthmatic bronchitis, ate a portion of cod-fish for her tea. She was later seized with abdominal pains and vomited. A generalized urticaria developed and she vomited several times. Her lips began to swell and she experienced difficulty in breathing. At this point I was summoned, and on arrival found her lips oedematous and her tongue almost filling the oral cavity. She was an ashen colour with gasping respirations and stridor. I injected adrenaline hydrochloride 1–1000 slowly minim by minim, and after about 10 minutes the stridor subsided and her breathing became easier and her lips and tongue became less swollen. I continued the adrenaline until I had given her 15 minims. She then had a violent attack of vomiting. She said she felt cold and her pulse was of poor quality; I gave 1 c.cm. nikethamide and she was wrapped in warm blankets in front of the fire. Her condition then improved considerably. Her husband had also had some of the fish without evil effect, so it does not seem likely that it was infected. This is an unusually severe case of food allergy in a susceptible subject.

Toothbrushes and Good Teeth

Dr. G. **Arbour Stephens** (Swansea) writes: An *ex cathedra* statement such as appears on page 793 of your issue of June 2 needs to be considerably modified. My experience of a very large number of child examinations is that the teeth of children to-day are in a far finer condition than they were 20 years ago, but there is no evidence that the sale of toothbrushes has increased during that period. One knows, however, that the intake of milk by children has increased enormously during that period, and, speaking with some authority, I consider the good teeth of to-day to be due to that fact. The greater intake of milk means an increased consumption of lime salts in a very absorbable form.

Disclaimer

Dr. **Gertrude Jefferson** writes: I desire to disclaim any authority for the publication of my name as the authoress of some remarks on the ill effects on women of queueing, in the *Daily Express* of July 13. In it I am wrongly spoken of as neurologist to the Manchester Royal Infirmary. I am in fact acting psychiatrist.

LONDON SATURDAY JULY 28 1945

SCRUB TYPHUS AS A WAR DISEASE

BY

Major-General Sir JOHN W. D. MEGAW, K.C.I.E., D.Sc., M.B.

When a request was received for a short article on certain aspects of scrub typhus it occurred to me that an outline sketch of some of the chief features of the disease might be useful to medical officers serving in the East. The following notes consist largely of impressions resulting from a study of reports of a considerable number of outbreaks that have occurred during the present war; no mention is made of the names of the authors, partly because several of the reports have not been published, and partly because detailed references would be out of place in an article of so limited a scope.

Relationship of Scrub Typhus to the other Typhus Fevers

A clear mental picture of scrub typhus can most easily be obtained by looking first of all at its relationship to the other typhus fevers, which it closely resembles in aetiology, pathology, symptomatology, and treatment. In these respects all the typhus fevers conform so closely to the same basic pattern that those who know any one of the diseases need pay attention only to the few points in which they differ from each other. But while in the above aspects the typhus fevers form a unitary group, scrub typhus and flea-borne and tick-borne typhus differ so sharply from classical louse-borne typhus in the epidemiological conditions in which they are transmitted to man that they must be placed in a separate subgroup. Louse-borne typhus, being transmitted from man to man by human lice, is a purely human or "demic" disease, so that, in prevention, infected persons and the lice by which they are infested are the chief concern. Scrub typhus—better named "mite-borne typhus"—together with flea-borne and tick-borne typhus, is primarily a disease of lower animals, or a "zootic" disease, and infection is transmitted to man as a secondary incident, so that measures of control are directed against the infected animals and the arthropod vectors which habitually feed on them. For all practical purposes the possibility of transmission of the zootic typhus fevers from an infected person to a contact can be left out of account.

In its epidemiology scrub typhus is more closely related to tick-borne than to flea-borne typhus, whose animal reservoirs live in association with human habitations, whereas the reservoirs of the other two diseases exist chiefly in rural and sylvan areas away from human dwellings. The resemblances between the fevers of the group are suggested by the name "typhus"; so, also, the differences are associated with the arthropod vectors and can most suitably be suggested by a nomenclature based on the names of the vectors. Mite typhus would be a more suitable name than scrub typhus, which implies that the disease is restricted to scrub country and which might even suggest that mite-borne typhus is the only typhus fever likely to be encountered in scrub areas.

Some Special Features of Scrub Typhus

Synonyms and History.—Although the name scrub typhus is of recent origin the disease was described in the third century by a Chinese writer, who attributed it to the bite of a "small red insect," presumably a mite. The classical form of the disease—tsutsugamushi ("small insect") disease—has been well known in Japan for many years, but the widespread distribution of the fever in the East was not realized till a few years ago because in outbreaks outside Japanese territory the local lesion called the "eschar" was seldom present, and as this was described as an essential feature of tsutsugamushi disease these outbreaks were regarded as being due to "new" fevers, to which many different names were applied. The eschar is now known to be a fortuitous feature, and all the mite-borne typhus fevers are the same as tsutsugamushi disease.

Definition.—Scrub typhus is the fever of the typhus group that is transmitted to man by a mite.

Geographical Distribution.—The disease is suspected of occurring sporadically in the north-eastern parts of Africa, but its definitely known range of distribution is confined to southern and eastern Asia, northern Australia, the islands adjoining these regions, and the Pacific islands. There is therefore a remarkably close association between the distribution of the disease and the areas in the East concerned with the operations of the war against Japan. In India, Ceylon, and the whole eastern theatre of war the disease can be expected to occur; the most dangerous areas are in South-East Asia and the South-West Pacific, where epidemiological conditions are specially favourable for the existence of infection.

Importance of the Disease.—Up to the outbreak of the Japanese War scrub typhus was not of great importance except to labour forces in certain localities. Most of the affected areas were sparsely inhabited and the indigenous populations were largely immune owing to attacks in childhood, so that nearly all the observed cases in these places occurred among the few persons who entered them from outside. Military preparations and operations introduced new conditions: large bodies of troops began to enter the infected areas, and outbreaks, sometimes reaching epidemic proportions, began to occur. Scrub typhus is now regarded as one of the major risks to life and military efficiency in the greater part of the war zone, and it has been found necessary to take drastic steps for its control. In one case hundreds of troops became infected after military exercises lasting a few days in an area where the very existence of the disease had hardly been suspected; in another a large proportion of the staff of a freshly established military hospital were attacked within a short time. Apart from the fatality rate, which may be anything from 1 to 20%, the average period of invalidity is more than three months, so it is not surprising that the disease is being attacked with great energy.

The Cause.—This is *Rickettsia tsutsugamushi,* also called *R. orientalis,* which is closely related to the other typhus rickettsiae in its morphological and cultural characters as well as in the pathological effects produced in the body; the chief difference between the organism and the related rickettsiae consists in the absence of a high degree of cross-immunity after infection.

Transmission of Infection.—The vector is a microscopic larval trombiculid mite; *Trombicula akamushi, Tr. deliensis,* and several other species are known or believed to be capable of transmitting infection from animal to animal and from animal to man. These mites bite only once during their lifetime, in the larval stage, so that the same mite cannot both acquire and transmit infection. What happens is that a mite infected by a blood meal can transmit infection through the egg to its off-

4412

spring, which can introduce the rickettsiae into any animal or human being on which they feed. This peculiarity in the life history of the mites has an important bearing on the methods of controlling the disease. The destruction of rats or other reservoirs of infection cannot have much immediate influence in stamping out infection ; it may even increase the risk to human beings by depriving the larvae of access to their usual hosts. The mites and the animals from which they derive their infection are most plentiful in places where the ground is damp and covered with grass and other vegetation. Grass, which grows to a great height in the Tropics, is specially liable to infestation ; swampy ground, scrub land, and places in which palm trees grow often swarm with the mites. Such places are usually situated near the sea, rivers, streams, or lakes. In dry places and during dry periods of the year the mites are not so active. Infection is often restricted to well-defined areas, but unfortunately it is seldom possible to judge by inspection which places are safe and which are dangerous. Persons who enter mite-infested areas are not likely to be bitten so long as they keep on the move, but the moment they sit or lie down, or even stand still, the mites are attracted and seek out a suitable part of the skin on which to feed. Any part of the body may be bitten, but the favoured sites are those bathed in perspiration and protected from disturbance by friction caused by the clothing. Such parts as the groins, scrotum, axillae, and neck are especially liable to be bitten. The mites when undisturbed remain attached for about two days ; they seldom cause pain or irritation, and often the victim does not know that he has been attacked.

Reservoirs of Infection.—Rats and mice are the animals chiefly concerned in maintaining infection among the mites. The complete chain of transmission has only once been clearly demonstrated, but there is convincing circumstantial evidence to support the accepted view on this subject. Analogy with the closely related disease, tick-borne typhus, suggests that infection can persist among the mites for long periods with very occasional refreshing by biting infected animals.

Pathology.—The essential features of the pathology of all the typhus fevers are remarkably similar. Apart from the effects of circulating toxins, special damage is caused to the organs and tissues of the body by interference with their blood supply. The rickettsiae multiply chiefly in the vascular endothelial cells, which become swollen or even proliferated. The walls of the capillaries and small arteries become infiltrated by mononuclear cells, chiefly lymphocytes, and in the tissues immediately adjoining these vessels there are often collections of similar cells. The special nervous and circulatory manifestations that occur in the typhus fevers are believed to be caused chiefly by damage to the central nervous system resulting from obstruction to the blood supply. The heart and other organs doubtless suffer to some degree from similar damage, but the modern view is that the circulatory failure is caused mainly by injury to the vasomotor centres, and to a minor degree by myocarditis. After defervescence a slow but complete return to normal occurs in the great majority of cases ; permanent damage to the brain or heart is quite exceptional.

Immunity.—There is complete immunity for a variable period after an attack, and, although this gradually diminishes, second attacks are likely to be less severe. Relapses have not been mentioned in any of the descriptions of the disease.

Clinical Features

The general resemblance between scrub typhus and the other typhus fevers is very striking. Apart from the eschar and lymphadenitis, which are often absent, there is no sign or symptom that can be relied on for the differentiation of a case of scrub typhus from one of classical typhus. The resemblance to tick-borne typhus is even closer, because the local lesion and lymphadenitis occur in some types of that disease.

In making a comparison between scrub typhus and the other fevers of the typhus group account must be taken of the great variations that occur in the virulence of the infection in each fever and also in the age and previous health of the groups of patients concerned. Just as louse-borne typhus may be a relatively mild or a highly fatal disease, so also scrub typhus shows a wide range of severity. The variability of scrub typhus is so important a feature of the disease that it deserves to be emphasized by giving a few examples based on descriptions of recent outbreaks among troops.

Analysis based on Recent Reports of Scrub Typhus

No. of Cases	Usual Type of Onset	Percentage Incidence of Eschar	Usual Range of Leucocyte Count	Fatality Rate (%)
50	Sudden	6	9,000–12,000	Nil
85	Gradual	80	4,000–6,000	3
626	Rapid	59	3,100–12,000	9·7
756	„	85	Relative lymphocytosis	·1
36	„	17	Moderate leucopenia	3

The rash was seen in most of the white-skinned patients, but in very few of the dark-skinned. In the outbreak in which the fatality rate was 9.7% there was only one death among the first 100 patients, but there were 37 in the next 150, who had been greatly debilitated by previous hardship and disease.

The general clinical picture must be viewed in the light of the above statements. Except when otherwise stated, the details can be filled in from any good description of classical typhus occurring among corresponding groups of persons ; the average type of the fever, the rash, the symptoms, the complete freedom from relapses, and the convalescence, conform to the same pattern in both diseases.

The incubation period ranges from 7 to 21 days. When the eschar occurs it usually makes its appearance before the onset of the fever ; it begins as a papule and soon becomes a round or oval sore, 2–3 mm. in diameter, surrounded by a red raised zone of about the same width. Soon a scab forms at the centre ; later this drops away, leaving a punched-out ulcer surrounded by a bright-red zone of skin. There is neither pain nor irritation, so that the patient is seldom aware of the existence of the eschar. Any part of the body may be affected, and the regional lymphatic glands are usually enlarged and tender.

The onset of the fever is as a rule rapid, sometimes with chill, and nearly always with headache of the post-orbital type ; pains in the loins and the limbs are common ; the conjunctivae are injected, the eyelids swollen, and the face looks bloated. A rapid step-like rise in the temperature follows, and the maximum is reached in two or three days. By the fourth or fifth day there is often a moderate degree of generalized lymphadenitis. The rash appears on the fourth to the seventh day, first as discrete macules on the trunk ; soon these become somewhat papular and the rash extends to the limbs. In most of the reported outbreaks the hands, feet, and face are said to have been seldom involved. In pigmented skins the rash can rarely be detected.

The patient's condition steadily becomes worse, and by the end of the first week the same types of mental symptoms as occur in classical typhus are usually observed ; there may be excitement or delirium with nocturnal insomnia, or the patient may be lethargic or stuporous. There often is a dry unproductive cough, associated with redness of the throat and bronchitis. The spleen is frequently palpable. The blood pressure falls, and during the second week the systolic reading is often below 100 mm. Temporary deafness, usually partial, is frequently observed, and there is increasing prostration. The leucocyte count may show little change, but a progressive leucopenia with a total or relative lymphocytosis is a common feature in many outbreaks. Leucocytosis, even up to 21,000 total count, has exceptionally been observed, but high counts are usually associated with secondary infections.

On the average the onset is rather less rapid than in louse-borne typhus, and there is a greater average tendency to daily remissions in the temperature curve. Leucopenia and lymphocytosis also are more frequent than in louse-borne typhus, but all these features are so variable that they cannot be relied on to differentiate the two diseases. Scrub typhus is said by some observers to differ from classical typhus in having few haemorrhagic, thrombotic, and septic complications, but these manifestations are equally infrequent in many outbreaks of classical typhus among young and previously healthy men.

The termination of scrub typhus is usually by lysis, which tends to be more gradual than that commonly occurring in classical typhus. The duration and severity of the attacks show the same wide range of variation as occurs in louse-borne and tick-borne typhus; there is also the same tendency to circulatory failure associated with a fall in the blood pressure. With recovery the circulation is gradually restored, and often there is sudden diuresis. Traces of albumin usually appear in the urine, but nephritis is exceptional.

The Weil-Felix Test

Strangely enough, the commonly used laboratory test for scrub typhus is based on the development of serum agglutinins, whose presence is indicated by the agglutination of a bacillus which has nothing to do with causing the disease. This is *Proteus OXK*, a bacillus derived by chance mutation from a strain of *Proteus OX 19*. In classical and flea-borne typhus *OX 19* is agglutinated in rising titre, and the reaction with *OXK* is negative or weakly positive. In scrub typhus these responses are reversed: *OXK* is strongly agglutinated and *OX 19* hardly or not at all. These bacilli thus serve as indicators of the types of the disease, perhaps in a manner analogous to the indications given by various sugars in differentiating the bacilli of dysentery and other diseases.

Carefully selected strains of *OXK* must be used; this organism, itself a mutation strain, is liable to undergo unexplained variations in its agglutination responses, but when standardized suspensions are used the test is as reliable for scrub typhus as the agglutination of *OX 19* is for louse-borne and flea-borne typhus. The rise in titre usually begins about the end of the first week of the fever and reaches its maximum about the end of the second week. The test should be carried out as early as possible and repeated at intervals, because the rising titre is of special significance; an initial negative reaction followed by a titre as low as 1:50 is stronger evidence than a single late reaction of 1:100 or even 1:200. Occasionally the reaction does not become positive till convalescence has set in. In patients who die before the 14th day the reaction often remains negative till death, otherwise it becomes positive in a very high proportion of the cases. False positives are rare when reliable suspensions are used.

As happens in other typhus fevers, the Widal reaction is often positive in scrub-typhus patients who have been inoculated with T.A.B. vaccine.

Complications; Prognosis; Convalescence

Bronchitis is a common complication, but is probably only a manifestation of the disease resulting from the multiplication of the rickettsiae in the respiratory mucous membrane. Bronchopneumonia also is probably a severe rickettsial reaction rather than a secondary infection. Secondary infections with pneumococci and septic organisms are infrequent except among patients who have been debilitated before the onset. Malaria is very prevalent in most of the places where scrub typhus occurs, and must constantly be borne in mind. In all cases of doubt a course of mepacrine should be given.

The average fatality rate in scrub typhus is about 5%. In outbreaks of low virulence among previously healthy young men it may be less than 1%, but in outbreaks of a virulent type in debilitated troops it may be as much as 20%, and in these circumstances elderly patients are more likely to die than to survive. In one outbreak there were six deaths among 13 officer patients, and four of these deaths were in persons over 35 years of age. Most of the deaths occur between the 7th and 21st days.

Convalescence is prolonged after severe attacks, but is usually complete in the long run. The average period of disability is about three months; during this time the circulatory response to exercise is poor, and a return to full duty may have to be delayed much longer. Final invaliding is likely to be necessary only in elderly patients who have had severe attacks.

Diagnosis

Few diseases are easier to diagnose when suspicion has been aroused, yet the all-important first cases in outbreaks have often been missed, with the result that preventive measures have been delayed. Now that the disease has become so notorious the most likely mistake is to make the diagnosis of scrub typhus in attacks of malaria or dengue, or to overlook the coexistence of malarial infection and scrub typhus.

If the eschar is present the diagnosis can be made at the very onset of the fever; otherwise a consideration of the exposure to risk and the early symptoms will often point strongly to scrub typhus, but a confident diagnosis may not be possible till the rash appears or the characteristic agglutination reaction becomes positive. Dengue may be closely simulated in the first few days, but its onset is usually more sudden and the epidemiological conditions in which it occurs are different. Flea-borne typhus may occur almost everywhere in the area of distribution of scrub typhus, but the chief risk of infection is in towns and villages, and outbreaks of considerable size are not likely to arise. The agglutination reaction in the flea-borne disease is of the *OX 19* type; the eschar and lymphadenitis are not present, otherwise the symptoms are very similar to those of scrub typhus. Tick-borne typhus also occurs in many places in the East, but no outbreaks have been reported from the theatre of military operations; the agglutination response is rarely of the *OXK* type, and if cases were mistaken for scrub typhus little harm would be done, as treatment and prevention are on almost identical lines. Louse-borne typhus is remarkably uncommon in the Tropics, even among louse-infested communities, but the disease can be expected to occur in subtropical China, increasing in frequency in the colder parts of the country. In northern China louse-borne and flea-borne typhus may appear simultaneously in one locality and so give rise to difficulties in differential diagnosis because the symptoms and agglutination reactions are the same in these diseases.

Although knotty problems in differential diagnosis may occasionally arise, few mistakes will be made if the epidemiological conditions are considered and serological tests are carried out.

Treatment

Treatment is on exactly the same lines as in louse-borne typhus except that no precautions are needed to prevent the spread of infection from the patient. No drug has yet been found to have a favourable influence on the course of the disease, though para-amidobenzoic acid may turn out to be of value in view of its successful use in some cases of classical typhus. Convalescent serum has had no obvious effect in the few cases in which it has been tried, and the attendant risks in malarious countries deserve consideration.

Careful nursing, preferably in the Fowler position, a generous varied diet rich in vitamins, and an adequate intake of fluid are generally agreed to be essential. At least four pints of liquid should be taken daily; given by the mouth, or if necessary by a nasal tube kept *in situ*, there is little risk of fluid retention such as may occur with the intravenous administration of salines and glucose. Supportive intravenous treatment should be undertaken only when expert laboratory help is available, but plasma may be needed in exceptional cases. The urinary output must be maintained; it should be measured every eight hours in serious cases. Digitalis and adrenaline seem likely to do more harm than good. Oxygen should be given if cyanosis develops. For intense and persistent headache lumbar puncture should be carried out.

The psychological factor in treatment is important. The patient is greatly helped by the maintenance of a cheerful atmosphere; he must not be allowed to receive the impression that his illness is of a mysterious and deadly kind; and care is specially needed to avoid any suggestion that his heart is likely to be permanently damaged. These patients are often fractious, so they must be managed with a judicious combination of firmness and kindness such as is suitable for mental cases. The diet should be varied; "something to chew" is helpful in maintaining the hygiene of the mouth, and when the patient's condition allows he should sit up in bed for his meals. Frequent changes in position and a careful watch for oedema and threatened bed-sores are needed for lethargic and comatose patients. Sulphonamides have not been effective for bronchopneumonia, presumably because this is caused by the rickettsiae rather than by secondary infections. Although penicillin has been disappointing, it is said to have been helpful in one case with bronchopneumonia.

Transfers of patients involving a tiring journey should never be permitted after the first few days. The pathology of scrub typhus should be borne in mind in planning treatment; the disease is essentially a rickettsial vasculitis. The patient must be warned against exertion till his response to exercise becomes satisfactory.

Prevention

Prevention has to be considered from two points of view—the protection of camp sites and of troops compelled to enter mite-infested areas. When a choice of camp sites is possible a dry area should be chosen. The site should be thoroughly cleared of all grass and vegetation by cutting, oiling if possible, and burning. Indigenous labour should be employed when available. For important camps a bulldozer would be invaluable; the ideal to be aimed at is to obtain a surface covered with earth or sand and completely free from vegetation. When this is impracticable an effort should be made to provide such a surface for occupied quarters and paths, and to prohibit all straying from the prepared ground. The work should, if possible, be carried out under the supervision of an expert entomologist. The protection of troops compelled to expose themselves to risk is a troublesome problem, complicated by the difficulty of designing mite-proof clothing which would be tolerable in tropical conditions. The detailed measures now adopted cannot, for security reasons, be completely divulged, but it is known that mite repellents, such as dimethyl phthalate, have been applied to the skin and clothing, and that intensive study of the whole subject has been carried out by competent experts.

The control of rats and other animal reservoirs of infection must be undertaken with great circumspection, and only under expert guidance, for the reasons already given. Rats should certainly be discouraged from infesting the camp by keeping every scrap of food out of their reach and by seeing that no suitable nesting-places are available for them. The camp should be kept free from animals of every kind; to ensure this a high standard of tidiness is needed, especially in cookhouses and food stores. Rat and mouse holes can safely be treated by cyanide gas; trapping and poisoning may be risky.

Prevention by egg-yolk or animal-lung rickettsial vaccines has been the subject of close investigation by experts, but many difficulties are likely to be encountered in work of this kind. The instruction of all who are exposed to risk must form an important part in the campaign against scrub typhus; success can be achieved only by the intelligent co-operation of everyone. There is plenty of evidence that the disease is being taken very seriously by the Allied Forces in the East, and there are good grounds for hoping that the energetic measures of control now being adopted will reduce the scrub-typhus menace to negligible proportions.

SCRUB TYPHUS: A CLINICAL STUDY

BY

M. C. MENON, M.B., B.S.Madras
Lieut.-Col., I.M.S./I.A.M.C.; Officer in Charge, Medical Division of an Indian General Hospital (C)

AND

COLIN IBBOTSON, M.B., Ch.B.
Capt., I.M.S./I.A.M.C.

During the period Nov., 1944, to Jan., 1945, 110 British patients suffering from scrub typhus were treated in a forward Indian general hospital. This paper is a summary of the clinical records of these cases and of impressions gained with regard to diagnosis, prognosis, and treatment. The patients were all drawn from units of a British formation which entered a small "typhus island" in N.E. Burma during the first week of November. The preventive measures now in force had not at that time been adopted, and the onset of symptoms in the first cases occurred on Nov. 17—that is, approximately two weeks after entry into the affected area.

The first group of patients were admitted to the general hospital on Nov. 27, and in the next three days the total number had reached 41 (1 officer and 40 B.O.R.s). In December there were 69 admissions (3 officers and 66 B.O.R.s), most of whom reached us during the first nine days of the month. After this date fresh cases were received only very occasionally, owing to more efficient prophylaxis and to the fact that the main body of the formation had driven beyond the endemic zone. At first, cases reached the general hospital on the fifth to tenth day of the illness. Later, as forward medical units became more "typhus conscious," the disease was recognized earlier, and patients were evacuated about the third or fourth day.

Clinical Features

The onset was usually sudden, with severe headache and fever, with or without a rigor. The *temperature* usually reached 103° within the first 48 hours, and was often slightly higher. Thereafter the fever was usually continuous, but a four-hourly chart sometimes showed an intermittent type, a sudden drop to normal or subnormal, accompanied by profuse sweating, taking place in the early hours of the morning. The average duration of fever was 15.7 days (extremes, 5 days and 29 days), the return to normal being by lysis. Twenty-five cases had fever of 10 days' duration or less. *Headache* was present in 100% of cases from the onset of the illness. It was often frontal or retro-orbital, and of such severity that it was not relieved by the usual analgesics. *Sore throat*, with injection of the fauces, was present in 54% of cases; it was so severe as to prevent swallowing in 4 cases (3.6%).

Primary Lesion or Eschar.—56% of cases showed typical eschars. The lesion was generally single, but 3 cases each had 2 eschars, and one case had 3. The eschar may be missed if the search is not thorough. In several cases the eschar was found on the scrotum, the perineum, or between the buttocks. The common sites, in order of frequency, were the axilla, the anterior aspect of the trunk, the forearm, the leg, and the back of the chest. The patients were rarely aware of the existence of the lesion, and in only two cases could the men recall having noticed it before the onset of general symptoms. These troops were so inured to jungle sores, however, that it is not surprising that they took little heed of an extra one.

Conjunctival injection and marked *flushing of the face* were common signs, being observed in 82% and 65% of cases respectively. They were of assistance in the early diagnosis of the disease, since they were present by about the third day.

Adenitis.—Of the cases 98% showed moderate enlargement of the lymph nodes in all areas. The glands were not visibly enlarged except in a small number, but were very readily palpable, discrete, rubbery, and sometimes tender in the first week or so. Enlargement was appreciable by the fourth day of the illness. Except in a few cases, the glands draining the eschar were not noticeably larger than those palpable elsewhere.

Rash.—In 64% of the cases there was a maculo-papular rash—more rarely purely macular—on the fifth or sixth day of the illness. It lasted three to four days and was distributed mainly on the trunk, the face, and the proximal portions of the limbs. One case presented unusual features, in that at the time of the maculo-papular rash, and healing as the latter faded, there were multiple superficial herpes-like erosions of the glans penis, similiar lesions of the buccal mucosa, and an oval sloughing ulcer of the lower lip. The Kahn reaction in this case was negative, which answered a suspicion that temporarily occurred to us, and the patient subsequently became the subject of typical typhus necropsy.

Mental State.—There was some definite alteration in 50% of the cases. This varied from a drowsy apathy with mental confusion, in average cases, to restlessness, delirium, and sometimes a "typhoid state" in grave cases. Mild cases showed no mental change other than that caused by the constant intense headache.

Respiratory Signs.—50% of cases had signs of a diffuse bronchitis, and they produced a variable amount of mucoid sputum which was occasionally blood-tinged or rusty. Unless the sputum became purulent or the total white cell count rose above 10,000 per c.mm., we regarded this as a rickettsial bronchitis or pneumonitis—part of the typhus syndrome, and not an indication for chemotherapy. Cyanosis and an increased respiratory rate were observed to be of grave prognostic significance. These signs did not often tally with the physical signs in the chest.

Hiccup was noted in 20% of cases, and was distressing to the medical and nursing staff as well as to the patients affected. It was a symptom of grave prognosis also. Six of our 9 fatal cases were thus affected. In some cases the symptom may be the result of enlarged mediastinal glands, though we considered it generally an indication of impending uraemia, the average blood urea in these cases being 80 mg. per 100 c.cm.

Chest Radiography.—A portable apparatus was not available; consequently cases were not *x*-rayed until the onset of convalescence. The first 8 cases at this stage showed completely normal chest films, after which the investigation was abandoned except when specially indicated.

Splenomegaly.—The spleen was palpable, sometimes easily so, in over 50% of cases. Since all patients were taking suppressive mepacrine, however, and 15 (13.6%) had demonstrable malaria parasites in the blood on admission, it was not possible to say to what extent typhus itself might have been the cause of the enlargement. We feel that, in an endemic malarious area, too much importance should not be attached to this sign.

Urinary System.—The urine, chemically and microscopically, was found to be normal. Neurological abnormalities—incontinence or retention—occurred in 15% of cases.

Cardiovascular Signs.—The pulse rate tended to be rather low in relation to the temperature in the first few days of the illness, but in the later stages of the acute phase it went up to 130 or more. Dilatation of the heart was not appreciable clinically. In downhill cases the blood pressure became progressively lower. The only positive sign, apart from tachycardia, occurred in 4 cases (3.6%) which manifested repeated extrasystoles. No bruits were heard. Tachycardia sometimes persisted well into convalescence.

Nerve Deafness.—This is probably a valuable sign, but one which we found difficult to assess owing to the profound apathy common in these patients and their slow cerebration. In general we found measured speech as well understood as a stentorian voice.

Neck rigidity and stiffness were noted in 6 cases (5.4%) in the early stages. The C.S.F. was clear and under normal pressure.

Blood Investigations.—The total red, total white, and differential white counts revealed no abnormality in the majority of cases. We attached significance to a total W.B.C. count exceeding 10,000 per c.mm. (see below).

Weil-Felix Reaction.—We took the agglutination of the Kinghbury strain of *B. proteus* (OXK) in dilutions of 1/125 or greater to be diagnostic. The average titre obtained on the 17th day of illness was 1/250, the greatest being 1/12,500 (19th day). We feel that the (OXK) titre is by no means indicative of the severity of the infection, and that a titre lower than 1/125 does not negative a clinical diagnosis. In our series 20 persistently gave positive results in titres lower than 1/125, but we have no doubt that they were cases of scrub typhus. In most instances the titre rose steadily during the first three weeks and then began to fall.

Complications

Lung Complications.—Bronchopneumonia (4 cases) and lobar pneumonia (3 cases) were observed. There were the usual clinical signs and a raised total white cell count, the increase being largely polymorphonuclear. Three of these cases developed empyema, two of them resolving after aspirations and local and parenteral penicillin, and one requiring rib resection. The pus aspirated revealed staphylococci and streptococci in one case and no growth in the second; in the third case, which failed to respond to penicillin, staphylococci were grown at first, but later *B. coli* (penicillin-resistant) was cultured.

Alimentary Complications.—Parotitis, 1 case; haematemesis, 1 case (fatal); diarrhoea, 3 cases.

Cardiovascular Complications.—Femoral thrombosis, 2 cases; unexpected myocardial failure during convalescence, 1 case.

Nervous Complications.—Transverse myelitis syndrome, 1 case; mild peripheral neuritis, 6 cases.

Bed-sores.—3 cases.

Concurrent Disease.—Malaria, M.T. or B.T., 15 cases (2 cerebral malaria); amoebic dysentery, 2 cases; dysentery, bacillary exudate, 2 cases.

Course and Prognosis; Morbid Anatomy

The fever usually lasted a little over two weeks. Recovery was rapid. Signs of ill omen were cyanosis, increased respiratory rate, hiccup, retention of urine, and gross mental changes. In our series 9 out of 110 patients died, giving a mortality rate of 8.2%.

One of our patients died unexpectedly four days after the temperature had reverted to normal. We found a flabby dilated heart with moderate fibrosis, and could point to no cause other than acute myocardial failure. One died after a haematemesis, and post-mortem examination revealed numerous submucous haemorrhages in the stomach and small intestine. The other seven deaths were attributable to toxaemia, and occurred between the 12th and 24th days of the illness. Enlargement of the mediastinal and mesenteric lymph glands was commonly found, with congestion of the liver, a soft enlarged spleen, and congestion of the lungs, sometimes with subpleural haemorrhages.

Diagnosis

Clinical diagnosis was easy owing to the presence of associated cases. A sudden onset with severe headache, followed by the combination of sustained pyrexia, enlarged rubbery lymph nodes, conjunctival injection, a maculo-papular rash, and an altered mental state—a combination which most cases presented by about the fourth or fifth day—will rarely be anything else even in the absence of an eschar. A typical eschar together with any of the above signs was considered diagnostic. The Weil-Felix reaction was of value as later confirmation, but reached significant levels too late to be of assistance in the early stages.

Differential diagnosis resolved itself into two phases—that before the lymph nodes enlarged, and that which pertained afterwards. In the first phase malaria and fevers of the dengue-sandfly group were likely to be confused. The onset in the case of enteric was usually not so abrupt. The cases which showed stiffness of the neck muscles gave rise to the suspicion of meningitis, which was excluded by lumbar puncture. Primary infections of the respiratory tract (streptococcal sore throat, acute bronchitis, bronchopneumonia, and lobar pneumonia) gave little trouble because of the correlation of other symptoms. In the second phase glandular fever, acute leukaemia, and agranulocytosis were excluded by a white cell count. In measles the first symptoms are coryzal, Koplik's spots will be present, and the temperature will fall before the rash appears. Secondary syphilis will very rarely be so severe, and the proportionate predominance of individual symptoms and signs will be different. Serum reactions will be positive.

Treatment

General.—In no disease is the physician less important except as a guiding force, and the nurse more essential. These particular patients were fortunate in having a ward sister who accepted this from the start and gave up practically all her "off-duty" time week after week. Nursing must be intensive and continuous, without which many patients who otherwise would live will inevitably die. An adequate diet was maintained—a minimum of 2,400 calories daily, including 100 g. of first-class proteins—and dehydration and salt depletion were combated. Most patients, with sufficient encouragement, took fluid and semi-solid nutriment by mouth. If not, the transnasal intragastric Ryle's tube was employed. Intravenous fluids tended to aggravate the respiratory symptoms, and in any case were of use only in a grave emergency. Vitamin concentrates of A, B, C, and D were available and were given to all patients as a routine. Since these patients came from a highly malarious area, a full course of mepacrine was given from the date of admission, followed by suppressive treatment. Pressure points and oral hygiene required constant attention. Rest in bed was enforced till the pulse rate settled to normal (usually 10 to 12 days after the temperature touched normal), and then patients were allowed to get up and move about gradually.

Symptomatic Treatment.—Insomnia, due usually to intense headache, was treated with potassium bromide, chloral hydrate, each 15 gr., and tr. opii. m. 15: or paraldehyde 6–8 c.cm. intramuscularly in severe cases. Paraldehyde by mouth was usually not tolerated. Hiccup was difficult to manage, and responded best, even though only temporarily, to inhalations of CO_2 and oxygen. Cyanosis and respiratory distress responded well to continuous oxygen administration, though this treatment had to be continued as long as three days in some cases. Patients with meningitic symptoms were lumbar-punctured, principally from the diagnostic point of view. Removal of cerebrospinal fluid did not appear to alleviate the symptoms.

Treatment of Complications and Concurrent Diseases

Lobar and lobular pneumonia due to secondary pyogenic infection were treated with sulphathiazole in the usual dosage. Of 7 cases so treated, 3 developed empyema. Treatment adopted for this was repeated aspiration followed by instillation of penicillin into the pleural cavity, combined with intramuscular penicillin in dosage of 100,000 Oxford units daily. This treatment led to resolution in two cases, but the third became contaminated with *B. coli,* and rib resection was necessary to complete the cure.

The case of parotitis cleared up without resort to surgery. The two cases of femoral thrombosis were treated along the usual lines, but recovery was marred by a residual oedema of the leg. Retention of urine called for twice-daily catheterization until bladder control was regained. Bacillary and amoebic dysentery were controlled with sulphaguanidine and emetine respectively.

Summary

A series of 110 cases of scrub typhus in British patients is described.

The disease generally presented a clear-cut symptomatology, and clinical diagnosis was not difficult.

The Weil-Felix reaction becomes positive in significant titre too late in the illness to be of much assistance in the early diagnosis.

The differential diagnosis and prognosis are discussed and the pathological findings in the fatal cases recorded.

We wish to thank Col. P. H. Addison, I.M.S., for permission to present this account.

THE EFFECTS OF MECHANICAL STRESSES ON MAN*

BY

B. H. C. MATTHEWS, C.B.E., Sc.D., F.R.S.

LECTURE II

In aircraft man moves at very high speeds, but high speed in itself does not produce any physiological effect if the pilot is protected from high wind-pressures in a closed cockpit. However, when motion changes rapidly, either in direction or in magnitude, the pilot is subjected to very great mechanical stresses not ordinarily met with on the ground. The practical effects of these may be separated into two classes of phenomena: (1) those associated with change of speed such as occurs in catapult-launching or in crash-landing, where high acceleration or deceleration acts for a short time; and (2) those associated with change of direction of motion, which may be of long duration but of less magnitude, as when an aircraft executes a tight spiral. The physiological effects produced depend on the value, duration, and line of action of the force acting on the body and also the area over which the force acts on the body. The magnitude of the force acting on a body, owing to its inertia during change of motion, depends on the rate of change of velocity and the mass of the body. The numerical factor to be related to physiological effects is the change of velocity in feet/second/second. The acceleration due to gravity giving a body its normal weight is 32.2 ft./sec./sec., abbreviated in the sign "g," and it is convenient in physiological work to consider the rate of change of motion in terms of multiples of "g." This makes it possible to give the forces acting a numerical value. It must be emphasized that the acceleration communicated to one part of the body, if it acts only for a very short time, may not produce so great an acceleration on other parts of the body owing to transmission of the forces via parts of the body which yield. For example, if the chair in which a man is seated is given an upward acceleration of 5 g for only one-fiftieth second, the acceleration at the head will have a much lower value and act for a longer time owing to transmission of the force through yielding parts of the body.

If large forces act on a small area the commonest result is a penetrating injury. It is forces acting over a small area in this way which produce all common accident injuries, and to prevent these it is important in aircraft design to avoid projections in the cockpit with which the pilot may come into violent contact if the aircraft is suddenly decelerated, as in crash-landing. Injuries of this type are greatly reduced by the use of properly designed harness to prevent motion of the body relative to the cockpit. Here will be considered only those cases where a large force acts on the body over a considerable area and penetrating injury does not occur.

Physiological Disturbances

Fig. 1 gives in diagrammatic form the tolerance of the seated body to acceleration when it is adequately supported to meet the force. This is drawn as two separate lines, to distinguish between short-acting forces, which may result in mechanical failure of parts of the body, and long-acting forces of lesser magnitude, which produce physiological disturbances, particularly of the circulation, without permanent structural damage. The upper part of the curve is only a rough indication, and requires further definition of the exact support of the body, which makes a very great difference to the tolerable acceleration. In other postures the tolerable acceleration varies widely. Thus in a standing man fracture of the lower leg is a possibility at 3 g, and is very likely to occur at 7 g. A seated man accelerated forward can tolerate very high acceleration, probably over 25 g. For acceleration in the reverse direction, such as the deceleration in crash-landing, the body must be restrained by a harness, and unless the head is restrained (which is not often practicable) neck injury may occur at less than 25 g. Above this, evisceration may occur. Very high acceleration can be tolerated if it acts on a man supported spread-eagle on his back—probably at least 250 g (de Haven, 1942).

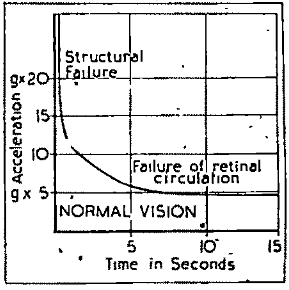

FIG. 1.—Acceleration tolerable to a seated man.

These figures must be regarded as a rough indication only, for unless conditions of support are exactly defined, wide variations may occur in practical cases. They are based on evidence from several sources—viz. (1) From experiment. Squad. Ldr. Stewart has carried out many catapult experiments with various postures, experiencing the accelerations which can be tolerated without injury. (2) From analysis of accidents, where it is often possible to reconstruct probable forces that have been in action. (3) From an analysis of unsuccessful suicide attempts which has been made by de Haven (1942).

The problem of concussion is too extensive to be considered here. The forces necessary to produce concussion, if penetrating injury does not take place, appear from de Haven's figures to be very high indeed, perhaps 300 to 400 g. Experiments by Denny-Brown and Russel (1941) also show that very high acceleration is required to produce unconsciousness in animals, though in practical rather than theoretical cases the work of Holbourn (1943) suggests that injury may result to the brain when the head receives a much lower acceleration if the force does not act through the centre of gravity of the head so that a sudden rotation is imparted to it. Damage to the brain may then result from its lagging behind the skull in rotation.

---

* The second of two Oliver-Sharpey Lectures before the Royal College of Physicians of London, March, 1945.

It is clear that these factors, and their proper application to aircraft construction and procedure, can do much to save life, especially in crash-landing, and much work has been carried out for the R.A.F., especially by Squad. Ldr. Pekarek, to give suitable protection to the body.

During prolonged acceleration physiological disturbances occur from the effects on the hydrostatic columns of blood in the body. Much physiological research has been carried out in the past on the effect of normal gravity on the circulation and the readjustments in the circulation which take place with change of posture. But in flight far greater forces, which easily produce unconsciousness, come into play.

"Blacking-out"

In the Schneider Trophy races pilots found that during turns at very high speed they suffered visual failure, which was given the name of "blacking-out." Experimental studies were carried out by R.A.F. medical officers Livingston (1939), Rook and Dawson (1938), Corner, and Wallace. Before the war intensive work on this subject was carried out in Germany, particularly by Ruff, by von Diringshofen (1934), and by Strughold. A centrifuge to reproduce the conditions of rapid turns was built in Berlin in 1935. By 1939 it was established that blacking-out was due to failure of the circulation above the heart owing to the great increase in effective weight of the blood while subjected to high acceleration. The subjective sensations under these conditions are those of a great increase in weight of all parts of the body. An increase to three times gravity makes it impossible to walk about, and at about four to five times gravity when seated it is impossible to raise the feet off the floor of the cockpit (Stewart, 1945). The pilot feels forced into his seat, and at 5 g, were his seat supported by a spring balance, it would indicate an apparent weight five times his own, so that a 200-lb. pilot would record about half a ton on the balance. This apparent increase in weight causes sagging of the soft tissues of the face, illustrated in the photographs (Fig. 2) of a subject in straight and level flight and during a tight turn. A number of R.A.F. aircraft have been equipped for research under these conditions, and a great deal of work has been carried out, particularly by Squad. Ldrs. Stewart, Davidson, and Watt.

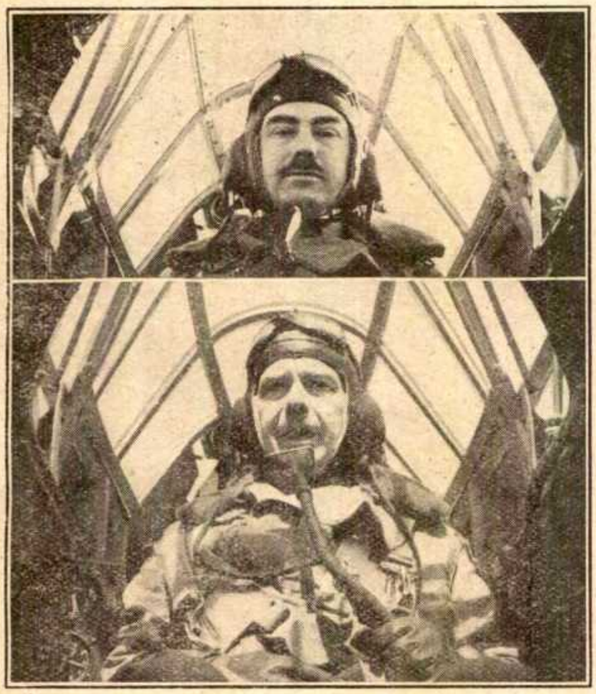

FIG. 2.—(i) Subject in straight and level flight. (ii) Subject at an acceleration of 4 g while turning. This illustrates the sagging of the soft tissues of the face owing to their virtual increase in weight.

A centrifuge operating on the ground can approximately reproduce these conditions without the added hazards of flight, although, owing to the rapid rotation necessary, other effects are brought into play. These are of secondary importance to the large centrifugal effects. Centrifuges to carry men have been built in Australia, Canada, and the U.S.A. The R.C.A.F. centrifuge (Franks *et al.*, 1945) at Toronto is shown in Fig. 3.

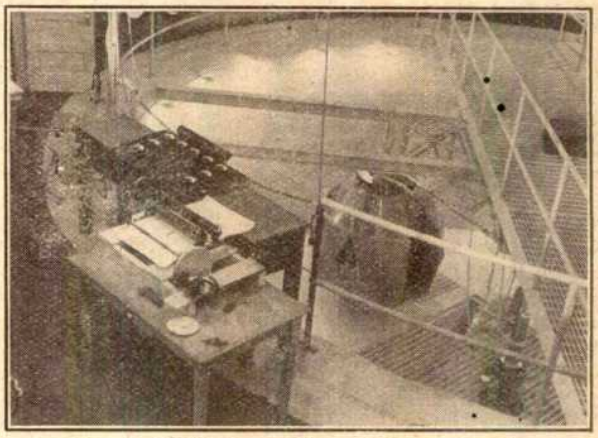

FIG. 3.—R.C.A.F. centrifuge, Toronto, Canada.

The effects of centrifugal force are primarily due to disturbance of the circulation. The blood virtually becomes the weight of iron at 7 g, and, if the circulation in the brain is to continue, a pressure of over 200 mm. must be maintained in the aorta to force it upwards against these forces. Moreover, the venous return from the lower half of the body falls and, unless inflow is maintained, clearly arterial pressure must also fall. In addition the normal circulatory reflexes are greatly disturbed when subjected to these conditions. The first symptom is loss of vision, and this is due to failure of the retinal circulation, which occurs before failure of cerebral circulation because the intraocular pressure is opposed to that circulation. This does not occur immediately the force is applied, but lags behind it some 5 to 8 seconds. This lag presumably represents the oxidative reserve available in the retinal cells themselves. Experiments by Craik and Stewart in 1941 showed that increasing the intraocular pressure by pressure applied to the eyeball produces blacking-out after about the same time interval as occurs while flying; and applying pressure to the eyeball while under acceleration in flight causes blacking-out to occur at values of "g" at which vision is unimpaired with normal intraocular pressure. With increasing acceleration when a pilot progressively tightens a turn, peripheral vision is lost and central vision becomes hazy before complete black-out. When just blacked-out, other cortical functions are less obviously impaired. Squad. Ldr. Stewart showed that hearing and smell are still functional; if the acceleration is still further increased unconsciousness results, with loss of muscular tone; as this occurs other neuro-muscular disturbances are seen. When the acceleration is removed consciousness returns rapidly, though after severe blacking-out convulsive movements of the limbs may be experienced, and the subject suffers retrograde amnesia and is disorientated (Franks *et al.*, 1945). The factors determining the severity of blacking-out are: (1) magnitude of the acceleration; (2) duration of the acceleration; (3) posture of the subject; (4) individual susceptibility.

So far a normal seated posture has been considered, and the average tolerance of acceleration under these conditions is roughly 5 to 6 g for five seconds.

Protection against Centrifugal Force

There are three practical methods of protecting the circulation against centrifugal force: (1) "Self"-protection: voluntarily increasing the tone by contracting muscles of the lower half of the body is found to increase by about 1 g the threshold at which blacking-out occurs. (2) Posture: by reducing the length of the columns of blood involved. This can enable a man to increase his tolerance of acceleration. Fig. 4 gives a diagrammatic summary of the effects of various postures on blacking-out thresholds. (3) Protection by the use of special garments.

In a normal sitting posture there are two processes leading to a failure of circulation in the head. The increasing weight of the blood requires increasing pressure in the aorta to maintain the circulation, and the venous side of the heart may be starved by pooling of the blood in vessels below that organ. This venous drainage may be reduced by surrounding the lower half of the body by a garment which applies equal pressure to the outside of the abdomen and lower limbs, to counter the outward pressure in the blood vessels while under acceleration.

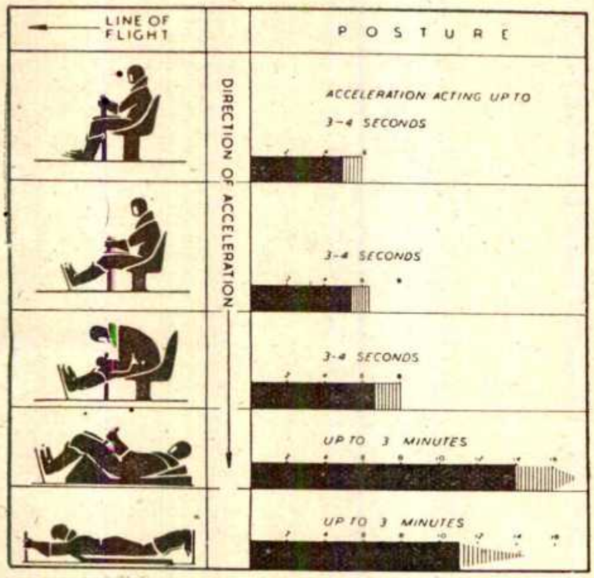

FIG. 4.—The effect of posture on the blacking-out threshold of a human subject (redrawn after Ruff).

The first scheme of this sort was that put forward by Marshall in 1933, using air bladders to compress the abdomen; the pressure being provided by the forward motion of the aircraft from a scoop which opened under the action of centrifugal force. An alternative scheme provided pressure automatically from a water-tank connected to the bladders at shoulder level. Flight tests showed that abdominal pressure alone was not entirely satisfactory, and much of the venous pooling occurred in the legs. A hydraulic suit to " pressurize " the thighs in addition to the abdomen, using water bladders within an inextensible suit, was worked out by Dr. Bourdillon in 1938, and submitted to the Air Ministry early in 1939.

In 1939 the late Sir Frederick Banting devoted much time and energy to organizing research in Canada on the development of anti-" g " garments, and Franks, working with him, constructed a number of suits on the hydraulic principle. After trials by the R.A.F. which established the effectiveness of this, a practical anti-" g " garment was produced from them by the research staff of the Dunlop Rubber Company, working with Wing Cmdr. Franks and Flying Officer Wilson. The Franks hydraulic suit was used in 1943 and 1944, but has now been discarded because, by the use of air pressure in place of water, effective protection can be achieved with a much less cumbersome garment.

Early in the war an air-pressure suit was developed in Australia by Dr. Cotton, working with the Australian Air Force, and using the centrifuge (McIntyre, 1945) which was set up there for the purpose. Since then the air principle has been very highly developed in America to give a comfortable and light garment which effectively pressurizes the lower limbs during turning in aircraft and enables the pilot to tolerate some 2 to 3 g beyond the point at which he normally blacks out. Development of air-pressure suits in the R.A.F. has followed on the principles worked out in America. The air-pressure suit is supplied from a pump on the aircraft engine via a valve operated by a weight acting against a spring, so that air is admitted only during positive acceleration in tight turns.

The blood below the heart is at a pressure which increases with the distance below the heart, and it was first thought necessary to apply a similar gradient in the external pressure applied to the surface of the body. The Franks hydraulic suit effected this automatically, as the gradient of pressure in the water is similar to that in the columns of blood in the limbs. The first air suits applied greater pressures to the lower parts of the legs than to the abdomen and thighs; but the advantages of this have not been found to be worth the added complications, and a single pressure applied to the body surface below the heart is very much simpler to achieve and will effectively maintain the circulation. The value of protection of the circulation during tight turns is that not only does it increase the manœuvres the pilot can carry out, which may be of value in " dog-fighting," but frequent application of acceleration insufficient to produce blacking-out is found to cause very marked fatigue, and this is avoided by the use of these garments.

It is at present undesirable to give pilots unlimited protection against acceleration. If this could be done many mechanical failures of aircraft would occur, for aircraft designers in the past have accepted strength limits based on the human tolerance of acceleration, and by making the man stronger than the aircraft in resisting " g " a new danger arises. There is also a physiological cause to avoid very high " g " until more perfect protection can be achieved; for with artificial maintenance of the venous inflow to the heart the great pressures required in the aorta to maintain upward circulation constitute a very great abnormal load on the heart and also raise problems of the structural strength of blood vessels at or below heart level. It is clear that if venous return is kept up and the acceleration increased still further, a point must ultimately be reached where myocardial and other damage will result. Animal experiments by Greenfield (1945) in England and Jasper and Cipriani (1945) in Montreal suggest that this limit is at about 12 g, and may well be lower in man. Fortunately, up to the present there has been no evidence of cardiac damage in the application of up to about 9 g; but it is clear that this is a very serious aspect of the problem, and if danger exists here it may not become apparent for a number of years after the conditions initiating it. It is therefore very desirable that, for the present, the loads placed on the heart in this way should be restricted.

The vascular system of the legs is able to tolerate very considerable increase in pressure during positive acceleration, though petechial haemorrhages are on rare occasions produced locally in the lower leg. However, the factor of safety for abnormally high pressures is very much less in the head. When an aircraft executes an outside loop so that the pilot's head is away from the centre of the circle, the blood is forced in the reverse direction from that already considered, and the pressure in blood vessels of the head may rise to a dangerously high value. An acceleration of about 3 g can be tolerated without danger, but a " redding out " of vision resulting from congestion of the retina may occur. Higher values of acceleration occasionally arise by accident, and haemorrhage in the conjunctiva is to be expected at 4 to 5 g. With higher values of acceleration there is a great danger of haemorrhage in the cerebral vessels, with serious and possible permanent damage to the brain, and for this reason manœuvres which would produce large centrifugal forces acting towards the head are avoided in aircraft.

Conclusion

In these lectures I have tried to give an outline of the two stresses to which large numbers of flying personnel are exposed. Our present knowledge on these problems has resulted from team-work not only on a national scale but, in the last few years, on an international scale between all the Allies. The extensive research organization that the Director-General of Medical Services, Sir Harold Whittingham, has set up for the R.A.F. is kept very fully occupied, and but for the great resources of our Allies and the Empire many of the problems could not have been studied in detail. In the R.A.F. the performance of men and machines has been stretched to the limit to outfly the enemy, but in civil flying the first aim must be to reduce stress on the passenger. While the stresses considered above should never arise in civil flying, knowledge from war research is applied to make civil aviation safer.

Perhaps it is not too much to hope that these researches carried out in the interests of war may prove of value outside aviation in peace. Our knowledge of normal function may often be increased by elucidation of function under abnormal stresses. One general truth is emphasized in this work—that is, the very great factor of safety in many physiological processes.

PERIPHERAL ARTERIAL EMBOLECTOMY

BY

PHILIP HOPKINS, M.R.C.S.

Surgical Registrar, King George Hospital, Ilford

The purpose of this paper is to review the literature on embolectomy, with special reference to the results; to stress the urgency of early diagnosis and prompt surgical treatment; and to describe a case in which a popliteal embolectomy was attended by success even though the time lapse between the occurrence of the embolism and the operation was greater than any other previously recorded.

Aetiology

The emboli we are concerned with are mainly derived from ante-mortem clot formed in the left side of the heart when stasis is present—chiefly in mitral stenosis. Occasionally the clot may be formed in the pulmonary or systemic veins; in the latter case the so-called "paradoxical embolus" occurs, being due to a persistent foramen ovale. But, nevertheless, cardiac dysfunction is the commonest cause: according to Danzis (1933) 60% of cases are due to cardiac disease, while of the 47 peripheral emboli recorded in Great Britain (in the available literature) 40 were of cardiac origin. Three of these occurred in thyrotoxic subjects with auricular fibrillation; the rest were in patients with mitral stenosis—the commonest single cause of embolism. Of the remaining 7, 6 were post-operative and one followed an accident which resulted in a fractured rib.

History of Arterial Embolectomy

Suabanejew, in 1895 (cited by Key, 1923), was the first to attempt "arteriotomy in order to remove a clot." He was unsuccessful, as were the next 11 surgeons who followed his example. Among these were Moynihan (1903; not recorded until 1907) and Handley (1907), in England; Stewart (1905; cited by Allen, 1929), Murphy (1909), and Carrel (1909; cited by Allen, 1929), in America; and Lejars (1902; Allen, 1929), in France.

The first recorded success was described by Mosney and Dumont (1911), when Georges Labey removed an embolus from the bifurcation of the left femoral artery six hours after its lodgment. The patient, a man of 38, had mitral stenosis, and made a good recovery. In the same year Gordon-Watson, in England, attempted to remove a post-operative embolus under similar conditions. The leg, however, had to be amputated later, but the patient survived.

Einar Key, of Stockholm, who was responsible for the second reported successful case, introduced the operation in Scandinavia, after Carrel's experimental work had made arterial surgery a practical proposition (Allen, 1929). By 1923 Key was able to report 12 further successes, mainly by Scandinavian surgeons. In 1923 Holst (Danzis, 1933) reported the first success in America, while it was not until 1925 that Jefferson described the first success in England. In 1928 Pemberton collected 216 cases of embolectomy, of which only 20 had been done in Canada and America, while 145 of them were Scandinavian. Twenty cases had been reported in England by Riddell (1935), but by this time there were 382 cases on record for Scandinavia alone. It is evident that the Scandinavian surgeons had accepted embolectomy as a useful operation, while the general practitioners in that country were co-operating by sending patients to hospital as soon as the diagnosis of peripheral embolism was suspected.

At the present time only 41 cases have been recorded in England; 47 emboli occurred in these, and embolectomy was carried out for 42 of them. The Registrar-General has, for the years 1941–3 alone, details of 34 deaths in which peripheral embolism played a part (personal communication), so there is no doubt that more than the 41 cases recorded have occurred in England since the time of Moynihan's first attempt.

Results

The main factor in the recovery rate of the *limb* in embolectomy is time—the time allowed to lapse between the lodgment of the embolus and the attempt to remove it. Pearse (1933) and Danzis (1933) have shown this to be true in their reviews of relatively large numbers of cases, which are expressed diagrammatically in Figs. 1 and 2.

The total successes reported in the past tend to give rather a gloomy impression (see Table), but on more careful examination it becomes apparent that if *all* cases could be treated within 4 to 6 hours of the impaction of the embolus in the artery, then the total number of recoveries might be very much greater. Dickson Wright (1933) in a postgraduate lecture stated that there is a 50% chance of recovery after embolectomy. Without operation the mortality rate in patients who have a peripheral embolus has been put as high as 87% (Danzis, 1933), with the majority of the remaining 13% having to undergo amputation of the affected limb.

Table showing Recovery Rates as found by Various Observers

Observer	Year	No. of Embolectomies	Successes	
			No.	%
Jefferson	1925	73	28	34·2
Danzis	1933	119	49	41·1
Pearse	1933	296	145	49·7
Key	1936	382	86	22·5
Hopkins	1945	42*	24	57·1

* This figure includes the 20 cases collected by Riddell (1935).

The ultimate prognosis, of course, is that of the causative disease.

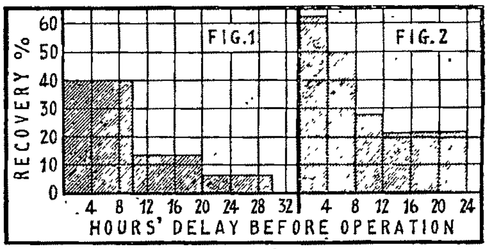

FIG. 1.—After Pearse (1933). 296 cases.
FIG. 2.—After Danzis (1933). 119 cases.

Successful cases have been reported in which more than 24 hours have elapsed between the embolism and the operation; the present case was not admitted to hospital until 39 hours' delay had occurred, and it is very interesting to note that a limb is capable of recovering even after this period of complete anoxia, provided that a good circulation can be restored. Holst (cited by Danzis, 1933) was successful with his case after 27 hours' delay, and Girdlestone's (1935) case recovered after 24 hours. It is apparent, therefore, that operation should be undertaken even when an unduly long delay has occurred, although it must still be emphasized that the optimum time for embolectomy is within 4 to 6 hours of the lodgment of the embolus. This consequently means that early diagnosis is essential.

Diagnosis

The leading factor in the diagnosis of peripheral embolism is that *something sudden happens in a limb.* Often a patien will liken his illness to a "stroke," and almost always he wi be able to give the exact time of its onset. The most commonl described symptoms are pain and paralysis in the affected lim but these are not constant. The pain may be agonizing; li a burning sensation; or merely be "pins and needles" or oth araesthesiae. A variety of symptoms can occur; the limb may eel "cold and numb," "as heavy as lead," "as though it were gripped in a vice," etc. Together with any of these there is often loss of voluntary movement. But, whatever the symptoms, they are of sudden onset in the majority of cases, and when they occur in patients known to be suffering from itral stenosis or other aetiological condition the diagnosis of mbolism should be made and the patient sent to hospital, or ther place where operative treatment can be undertaken.

Objectively the limb is cold from 1 to 2 in. below the site of lodgment of the embolus (see Fig. 3). Pallor or cyanosis may be evident, and there may be mottling or lividity below a line of demarcation. Arterial pulsation is absent distally, while pressure over the site of the embolus causes pain. Below it there may be loss of cutaneous sensation, and the deep reflexes may be absent.

The one other lesion which may really simulate embolism is n arteriospasm. This can be definitely excluded only by use of the Pachon oscillograph (Atlas, 1942), but this machine is seldom available. Graham (1937) has employed papaverine hydrochloride to relax vasospasm; but since this has no effect on embolism its value can only be in diagnosis, and it should not be used unless facilities for immediate operative treatment are at hand.

As stressed above, it is the time factor which is of the greatest importance, and this has been emphasized in all previous papers on the subject. Hamilton Bailey (1944) stresses that the occurrence of a peripheral embolus is as urgent a surgical condition as a perforated gastric ulcer.

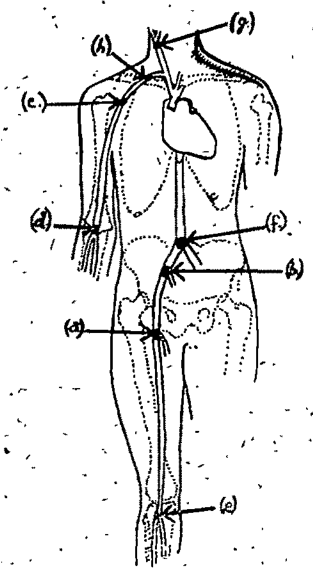

FIG. 3.—Usual sites of lodgment of peripheral emboli (after V. H. Riddell). 382 Swedish cases reviewed by Key, 1936.

(a) Femoral A. ..	54.4%	(18)
(b) Iliac A. ..	17.2%	(2)
(c) Axillary A. ..	11.8%	(1)
(d) Brachial A...		(12)
(e) Popliteal A...	11.3%	(5)
(f) Aorta	4.5%	(7)
(g) Carotid A.. ..	—	(1)
(h) Subclavian A.	—	(1)

(Figures in brackets represent the distribution of the 47 emboli recorded in Great Britain.)

Cases are very often sent to hospital too late for surgical intervention; Guthkelch (1943) mentions eight such cases seen at the Manchester Royal Infirmary. It would seem, therefore, with this and the Registrar-General's figures (see above) in mind, that many limbs—and lives—might be saved if early diagnosis and prompt surgical treatment could be instituted in these cases.

Case Report

On Jan. 2, 1945, a 43-year-old housewife awoke to find that both her legs felt numb. After some 30 minutes this wore off, and she remained comfortable until 10 a.m. on Jan. 4, when she experienced a "sudden agonizing pain in the left thigh" and noticed that her foot went "mauve." The pain continued, and by the next morning she felt as though her "thigh-bone was on fire" while her "flesh was numb like lead." On the evening of Jan. 5 she was admitted to hospital. The only relevant part of her history is the fact that she had had chorea at the age of 11, and that for some months before the present illness she had been getting more easily tired and out of breath, culminating in an attack of breathlessness and pain in the chest, which was taken to be coronary thrombosis, and for which she was being treated at home in bed, where she was when the pain in the leg started.

n examination she was found to have an advanced mitral nosis, with a regular rapid pulse; B.P. 85/60. The left leg was ite and cold from about 1 in. below the knee, with definite mottling of the skin of the foot. The femoral pulse was palpable on both sides at the groin, while the dorsalis pedis pulsation was palpable only on the right side. The left popliteal artery was tender to pressure and felt hard. Below the knee there was no cutaneous sensation, and the deep reflexes were absent.

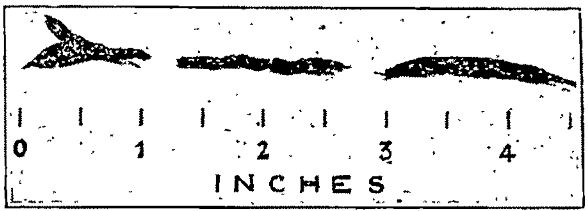

FIG. 4.—The embolus removed from the left popliteal artery. The first part, showing a bifurcation, was withdrawn from the distal end of the vessel.

Under local analgesia I exposed the popliteal artery, which was solid and in spasm. A small longitudinal incision was made in its lower part, and it was found to be filled with blood clot. Attempts to pick this up showed it to be friable. A fine rubber catheter, with its end cut off at an angle of 45°, was passed distally into the popliteal artery. A sucker was attached, and with the pressure at 76 cm. of water the catheter was slowly withdrawn, bringing with it the first part of the embolus, shown in Fig. 4. A flow of dark fluid blood followed. This was controlled with a tape passed around the vessel, and the above procedure was repeated in the proximal part of the popliteal artery. In this way the second portion of the embolus was delivered, but no bleeding followed. After several further unsuccessful attempts I decided to open the femoral artery, and this was done after dissecting it free in the lower end of Hunter's canal and closing the incision in the popliteal artery with a continuous suture of horsehair dipped in liquid paraffin. By means of the catheter as above the third part of the clot was removed, and this was followed by a torrential flow of bright red blood. While the flow was controlled by a tape the incision was closed, and on its release the vessel filled distally, but no pulsation was visible in the popliteal artery, which was found to be hard again. The first incision was reopened and fresh blood clot was removed and the artery resutured. This time it pulsated, and blood could be seen oozing through the needle punctures. Hot packs were applied, *and within five minutes the patient volunteered the statement that her foot was "tingling."* The wound was sutured and a drain was left in its lowest part. Twenty minutes later a good circulation was apparent by the rapid return of colour to the toes after blanching by digital pressure. In 24 hours the cutaneous sensation and deep reflexes had fully returned, and, apart from slight wound infection, convalescence was uneventful for three weeks. She then had started to get up and was able to walk a short distance. At this time she developed sudden abdominal pain. Apart from abdominal tenderness nothing was found on examination. There was good pulsation in both femoral arteries and also in both dorsalis pedis arteries. T. 101.2° F.; P. 98/min. regular. The possibility of a mesenteric embolism could not be excluded, and after several hours' observation without any improvement a laparotomy was carried out by a colleague, who found nothing abnormal. There was only slight pain the next day, and her convalescence continued to be uneventful. She was discharged home on Feb. 22, and is continuing her normal life so far as her cardiac condition will allow.

Treatment

As soon as peripheral embolism is diagnosed the limb should be lowered (not raised), and surrounded by ice-bags (not hot-water bottles), as the metabolism of the anoxic tissues must be reduced (Hamilton Bailey, 1944). Ideally, operative removal of the embolus should be carried out within 4 to 6 hours, but, as pointed out above, delay over this time need not preclude the possibility of recovery after embolectomy. No patient has been reported as having died owing to this operation, while the mortality rate in patients suffering from embolism of peripheral arteries has been put as high as 87% (Danzis, 1933) in those who have not been operated on.

Two other forms of treatment have been described: the first is conservative, and consists in the use of vasodilator substances (papaverine hydrochloride) and the application of alternating suction and pressure to the limb (Graham, 1937). Its value is dubious. The other method is surgical, and is arteriectomy. It was described first by Gosset *et al.* (1933); later Leriche *et al.* (1937) recorded 78 cases in which it was used, but although successful in some forms of arterial disease it was of little value in embolism.

The statistics for embolectomy, however, do show a reasonable chance of recovery in a person who is otherwise almost certain to lose a limb, and maybe his life. With this in mind it can be said that this form of treatment is the one that should be adopted in all cases of peripheral embolism, especially where the diagnosis is made early.

The recent advent of heparin (Murray and Best, 1938) may increase the chance of recovery still further, although a word of warning may be added here. For the first three days post-operatively the "specified dosage of 4,000 Toronto units" was injected intravenously daily, and at the end of this period the blood-clotting time was still only 3½ minutes at 37° C. As its further use did not seem to be indicated the heparin was discontinued. Its effect in this case was obviously unsatisfactory, and it seems that the dosage advocated will have to be increased, and in addition very careful laboratory control must be used. There is no doubt that this drug is valuable, however, as shown by MacFarlane's (1940) case, in which he performed four separate embolectomies in the same patient with complete success; similarly it had a marked effect on the clotting time of the blood in Hamilton Bailey's (1944) case.

Summary

A brief history of the use of the operation of embolectomy is given, together with the results obtained in the past; a special note about the British cases on record is included.

The aetiology, diagnosis, and treatment of peripheral embolism are discussed.

A further case is added to the records: successful popliteal and femoral embolectomies 39 hours after the lodgment of the emboli.

I would like to express my thanks to Mr. Harold Dodd, F.R.C.S., for permission to record this case.

The report for 1944 of the Kashmir Medical Mission of the Church Missionary Society has been received from Srinagar. The year is noted as an "absolute record" for this hospital, which, for many years under the guidance of Dr. E. F. Neve, has been regarded as one of the foremost medical missionary institutions in India. Over 48,000 visits of patients were recorded in the out-patient department and 2,707 were admitted to the wards. Though the valley of Kashmir enjoys one of the best climates in the world, the insanitary habits of the Kashmiris have not changed in the passing centuries. Outbreaks of cholera, dysentery, and typhoid persist and make possible the devastating epidemics which from time to time occur. The report is a good record of how war difficulties have been overcome—shortage of staff as also of drugs and dressings.

HIGH-COLOUR-INDEX ANAEMIA DUE TO VITAMIN C DEFICIENCY

BY

B. GOTTLIEB, M.D., M.R.C.P.

Senior Resident Physician, St. Alfege's Hospital (L.C.C.)

During the spring and summer of 1943 four severe cases of adult scurvy associated with a high-colour-index anaemia of varying severity were admitted to St. Alfege's Hospital. They were all males, aged 70–80, old-age pensioners who were living alone. The diet in each case was markedly deficient in vitamin C. The most severe case ended fatally from heart failure soon after admission, but the other three responded satisfactorily to ascorbic acid. Cases 1 and 3 had hydrochloric acid present in the gastric juice in normal amounts. In the other two the gastric juice was not examined. They all received a mixed hospital diet, but were not given haematinics such as liver, iron, or vitamin B complex; yet the anaemia responded satisfactorily to saturation with ascorbic acid.

Case Histories

Case 1.—A man aged 72 was admitted on Aug. 24, 1943, with extensive bruising and purpura on the backs of his lower limbs. The spontaneous bruising had appeared three weeks previously and was becoming more extensive. He was edentulous, and his gums were unaffected. His diet had consisted almost entirely of bread, margarine, a little jam, and stewed meat, but almost no potatoes or greens. He was anaemic, and the capillary fragility (Hess) was raised. The blood count on admission was: R.B.C., 2.4 millions; Hb (Haldane), 60%; C.I., 1.25; average diameter of R.B.C., 8 μ; reticulocytes, 0.8%; platelets, 144,000 per c.mm.; W.B.C., 5,000 (polymorphs 82%, lymphocytes 10%, monocytes 8%); bleeding and clotting times normal. Hydrochloric acid was present in the gastric juice in normal amounts. He was saturated with 11.2 g. of ascorbic acid intramuscularly in 16 days. The bruising and purpura began to fade in a few days, and rapid improvement resulted. The capillary fragility test became normal in three weeks. The anaemia responded satisfactorily, as shown:

24/8/43: R.B.C., 2,400,000; Hb, 60%; C.I., 1·25; W.B.C., 5,000
9/9/43: R.B.C., 3,250,000; Hb, 74%; C.I., 1·13; W.B.C., 5,600
17/9/43: R.B.C., 4,300,000; Hb, 86%; C.I., 1·0; W.B.C., 6,000

The maximum reticulocyte count was on 1/9/43, when it was 1.6%.

Case 2.—A man aged 79 was admitted on July 2, 1943, with severe bruising and purpura, especially of his gums and the left lower limb, the latter being also swollen. The papillae of his tongue were atrophied. He was markedly anaemic, and the capillary fragility was raised. His diet had been deficient in greens and potatoes, and had consisted almost entirely of bread, margarine, cheese, and meat pies. After saturation with 9.1 g. of ascorbic acid intramuscularly in 13 days, rapid improvement resulted. The capillary fragility test became normal after one month. He refused a gastric-juice examination. The anaemia responded satisfactorily, as shown:

3/7/43: R.B.C., 2,080,000; Hb, 54%: C.I., 1·2; W.B.C., 4,500
16/7/43: R.B.C., 3,500,000; Hb, 58%; C.I., 0·83; W.B.C., 3,800
23/7/43: R.B.C., 4,100,000; Hb, 72%; C.I., 0·88; W.B.C., 4,700
15/9/43: R.B.C., 5,650,000; Hb, 108%; C.I., 0·95; W.B.C., 9,000

Case 3.—A man aged 76 was admitted on May 29, 1943. Three weeks previously he noticed spontaneous bruising of his upper and lower limbs, which became more extensive and confluent. His gums were normal (he was edentulous), but he had numerous petechiae in the mucous membrane of his mouth. His diet had consisted almost entirely of bread, margarine, and cheese. He was markedly anaemic, and the capillary fragility was raised. He was saturated with 11.2 g. of ascorbic acid intramuscularly in 12 days. After a few days of this treatment the ecchymosis and purpura began to fade and rapid improvement took place. The capillary fragility test became normal in six weeks. Hydrochloric acid was present in his gastric juice in normal amounts. The anaemia responded satisfactorily, as shown:

31/5/43: R.B.C., 1,700,000; Hb, 38%; C.I., 1·11; W.B.C., 2,500
10/6/43: R.B.C., 2,540,000; Hb, 50%; C.I., 1·10; W.B.C., 2,180
5/7/43: R.B.C., 3,100,000; Hb, 74%; C.I., 1·20; W.B.C., 3,000
14/9/43: R.B.C., 3,870,000; Hb, 84%; C.I., 1·07; W.B.C., 4,500

He died as a result of myocardial degeneration and congestive heart failure on Oct. 30, 1943.

Case 4.—A man aged 79 was admitted on May 5, 1943, with a history of three months' spontaneous bruising of his upper and lower limbs. His diet had consisted almost entirely of bread, margarine, and cheese. On admission he was found to have extensive bruising and purpura of his upper and lower limbs. His gums were spongy and bruised, and they bled easily. The capillary fragility was markedly raised, and he was markedly anaemic. The blood count was: R.B.C., 1.35 millions; Hb, 28%; C.I., 1.04; W.B.C., 3,000. He died five days after admission as a result of congestive heart failure.

Comment

About 70% of cases of scurvy have an associated anaemia, according to Mettier *et al.* (1930). Although most cases described are normocytic, reports of cases of scurvy associated with macrocytic anaemia have been described previously by Parsons (1938)—two cases of infantile scurvy; Dunlop and Scarborough (1935), Nisenson and Cohen (1937), and Jennings and Glazebrook (1938)—one case each of adult scurvy. Perhaps the severity and duration of the clinical scurvy determine the nature of the anaemia. Thus a comparatively early and mild case would have a normocytic anaemia, and a more severe and long-standing case which may interfere with maturation of the red blood corpuscles at an earlier stage would have a macrocytic or even an aplastic anaemia. It is of interest in this respect to note that Wohlbach (1937) found the red bone marrow replaced by homogeneous amyloid-like material in guinea-pigs fed on a vitamin-C-deficient diet for a long time. The bone marrow was studied by Jennings and Glazebrook in their case, and they found the appearances to be similar to that of pernicious anaemia.

Mettier *et al.* (1930) proved conclusively that the anaemia of scurvy responded to orange juice with a maximum reticulocyte response on the fifth to eighth day. Moreover, in two of their cases iron and liver had no effect on the anaemia. Mettier and Chew (1932) cured the anaemia of scurvy in guinea-pigs by orange juice. Dunlop and Scarborough (1935) confirmed the specific effect of vitamin C on the anaemia of scurvy by giving their patients a diet similar to that which produced scurvy, and the anaemia responded satisfactorily to ascorbic acid. One of their patients had a high-colour-index anaemia.

Whether subclinical scurvy can produce anaemia or not is uncertain. Dyke *et al.* (1942) described three cases of "irresponsive" pernicious anaemia which improved when ascorbic acid as well as liver was given. They did not, however, give details of the diet of their patients. It would, however, seem reasonable to treat cases of macrocytic anaemia having a history of vitamin C deficiency with ascorbic acid, particularly if hydrochloric acid is present in the gastric juice, before a diagnosis of refractory anaemia is made.

In the group of cases described above vitamin C deficiency appears to have been responsible for the high-colour-index anaemia. It may be argued that some factor in the hospital diet could have been responsible for the improvement in the anaemia and not the ascorbic acid. I consider this unlikely, since the diet did not contain any liver; and iron and the vitamin B complex, the other recognized haematinics, were not present appreciably above minimal requirements.

Summary

Four cases of "bachelor scurvy" associated with a high-colour-index anaemia are described.

The scurvy, as well as the anaemia responded satisfactorily to ascorbic acid given intramuscularly and a mixed hospital diet in three cases, without the addition of haematinics such as liver, iron, and vitamin B complex. Vitamin C deficiency is considered to have been the cause of the anaemia.

It is suggested that ascorbic acid therapy should be tried in cases of macrocytic anaemia whose diets are deficient in vitamin C, particularly if hydrochloric acid is present in the gastric juice before a diagnosis of refractory anaemia is made.

My thanks are due to Dr. B. A. Young, medical superintendent, and the medical and nursing staff of St. Alfege's Hospital, especially Sister V. Sinclair, for their co-operation, and to Dr. E. N. Allott, of the Lewisham Group Laboratory, and Mr. J. Puxley, laboratory technician, St. Alfege's Hospital, for the pathological investigations.

Medical Memoranda

Treatment of Human Cutaneous Anthrax with Penicillin

In view of the fact that few clinical reports of the treatment of human anthrax by penicillin have been published the following case may be of interest.

Case Record

An old, well-nourished, well-preserved ex-chief, a large cattle-owner, aged about 70, was admitted to hospital on May 4, 1945, with a history of a swelling in the neck of five days' duration. On examination there was a large fairly painful indurated swelling below the left jaw, covered by a black eschar about 3 by 1½ in.; much oedema and induration surrounded this area, spreading particularly round the front of the neck. A smear from the edge of the eschar showed anthrax bacilli, no other organisms being seen The patient was very ill; his temperature was 102.2° F., the pulse was poor, and he was mentally very confused; the lower margin of the spleen was at the level of the umbilicus, was moderately soft, and was painful on palpation. The blood slide was negative on two occasions for malaria parasites.

In spite of the fact that, in general, anthrax lesions in this part of the world respond well to N.A.B., it was decided, in view of his age and his very poor general condition, to give penicillin. This was accordingly started. 20,000 units of the sodium salt being given intramuscularly, followed by 10,000 units three-hourly by the same route, to a total of 200,000 units. Fluids at the rate of about 4 pints a day were given—at first by a gastric drip, and finally by mouth.

The clinical response was remarkable. Sixteen hours after administering penicillin the temperature was normal, induration and oedema surrounding the lesion were markedly less, the spleen had contracted slightly, and the general condition was much improved. The eschar appeared to be drier but slightly bigger. The penicillin was stopped 54 hours after its start. By this time the patient's general condition was very good, the induration and oedema of the neck had completely disappeared, the temperature had remained normal, and the spleen had contracted by about 1½ in.; smears from the lesion revealed no anthrax bacilli, and no other organisms were seen. Over the next two days the eschar separated, leaving a large ulcer about 4 by 1½ in. with a clean but deep granulating base; the spleen had contracted by 2 in. from its initial size. Unfortunately, on May 12 the patient developed a pneumonic consolidation of the base of the right lung, associated with a recrudescence in temperature and accompanied by severe hiccup; this responded rapidly to sulphathiazole, the hiccup being controlled by morphine. At the time of writing, May 21, the patient was convalescent, and the ulcer had nearly healed.

Comment

Both the malignant pustule and small outbreaks of intestinal anthrax, contracted from eating infected meat, are fairly often met with in this district. In general, the malignant pustule does not appear to have the same severity as cases encountered in England; and, as has already been said, these cases respond well to large doses of N.A.B. The infection in question, however, was of a particularly severe type in an old man, and the prognosis seemed to be very poor. In addition it appeared that the condition was becoming generalized, although no anthrax bacilli were seen in any of the blood slides. The patient lives in a hyperendemic malarial area, and it was known that he had had splenomegaly previous to the onset of the disease. His blood slide on five occasions within the first three days of admission was negative for malaria parasites, and it was thought that the changes in the size of the spleen were more likely to be due to an anthrax septicaemia than to a malarial relapse. He was given no antimalarial therapy.

The improvement shown after starting penicillin was dramatic. Since treating this case. I have read an extract describing the treatment of three cases of human cutaneous anthrax in the United States by Murphy *et al.* The American authors recommend that 200,000 to 400,000 units should be given at the rate of 100,000 units in 24 hours to the average adult, and they appeared to favour continuous intravenous infusion of the drug. In the case described above, 200,000 units, given over 54 hours by intramuscular injection every three hours, were quite sufficient to obtain a prompt and lasting response, the general condition of the patient and the local condition of the pustule being greatly improved after the first 100,000 units.

I would like to thank the Acting Director of Medical Services, Kenya, for permission to publish this note.

Reviews

DIFFERENTIAL DIAGNOSIS

An Index of Differential Diagnosis of Main Symptoms, By Various Writers. Edited by Herbert French, M.D., F.R.C.P., assisted by Arthur H. Douthwaite, M.D., F.R.C.P. Sixth edition. (Pp. 1,128; 798 illustrations, of which 231 are coloured. £4 4s.) Bristol: John Wright and Sons.

The publishers are certainly to be congratulated on producing a sixth edition of French's *Differential Diagnosis* in wartime. The book is beautifully printed and easier to handle than pre-war editions. There are large numbers of photographs, radiographs, and coloured pictures, all of which are excellent reproductions, and there is a full index. The middle-aged critic cannot easily forget the fascination with which he first turned the pages of this book immediately after the last war, and he must wonder what will be the reaction to it of the present generation of students and housemen. It is not easy to keep up to date a work which first took form 33 years ago. Disease, it is true, remains much the same, but the background against which it is enacted and the methods by which it is viewed are very different. We are not now so passionately interested in the differential diagnosis of rare and incurable diseases, and the subtle distinction between a chylous and a chyliform effusion leaves most of us rather cold; the matter can rarely be of much individual or general importance. In 1912 it was still perhaps fashionable advice to leave physiology behind when one entered the wards and to adopt the outlook of the collector or, at best, the field naturalist. Nowadays we think in terms of altered physiological processes and biochemical tests, rather than the long lists of causes of symptoms which Dr. French and his collaborators have compiled. It would be possible for the student to read the section on ascites without appreciating the fundamental importance in diagnosis of trying to determine the systemic venous pressure, the portal pressure, and the serum proteins. Here, too, constrictive pericarditis is very incompletely displayed. Under lardaceous disease the value of the Congo-red test is not discussed, and under lymphadenopathy the impossibility of diagnosis without biopsy is inadequately stressed. The section on pigmentation of the mouth is a very sound bit of clinical writing, beautifully illustrated, but special tests for Addison's disease, such as *x*-ray examination of the lungs and suprarenal glands, or measurement of the ability to retain sodium, are omitted. Under acute yellow atrophy, on the other hand, tests for leucine and tyrosine in the urine are recommended, though the modern emphasis is on clinical features, such as persistent vomiting, nervous symptoms, and ascites, and examination of the urine is of little value. Homologous serum jaundice does not appear to be mentioned.

The technique of clinical diagnosis by personal observation reached its heyday in the age of therapeutic nihilism, when diagnosis seemed an end in itself. To-day, diagnosis is merely a means to an end, and this is why scientific precision, short cuts, and laboratory data are the rule of the day. We may lament the passing of the clinical diagnostician as of other craftsmen, but we have to remember that the modern patient with pneumonia expects to be nursed in hospital, and the modern houseman expects to be able to *x*-ray such a patient on the way to the ward and begin treatment at once with a sulphonamide drug. French's *Differential Diagnosis* contains much that is of immense professional interest and of undoubted value to the student, but it is doubtful whether it accurately reflects the diagnostic practice of the active physician of the present day.

NEUROLOGY

Diseases of the Nervous System Described for Practitioners and Students. By F. M. R. Walshe, M.D., D.Sc., F.R.C.P. Fourth edition. (Pp. 360; illustrated. 15s. plus 7d. postage.) Edinburgh: E. and S. Livingstone. 1945.

The fourth edition of Dr. Walshe's small textbook on nervous diseases has appeared when book production is in a most difficult period. The demand for it shows that the student and the practitioner have appreciated what a useful survey of a complicated subject has been given to them.

Dr. Walshe is distinguished for his sound if conservative common sense, and has always refused to be led away by new speculations and enthusiasms until they have stood the test of time. Especially is this the case with reference to the psychological approach. In this edition he refers to psychosomatic conditions but gives very little space to their consideration. For example, he still treats with scorn the psychological explanations of enuresis in children, saying that the syndrome points to a hypothalmic dysfusion, is therefore physiological, and the children are just made like that. He admits that treatment along physical lines is seldom successful, and hopes that the symptom will disappear at the age of twelve. He ignores the possibility that the hypothalamic dysfunction may be psychogenically determined and the fact that psychological treatment does very often remove the symptom.

New material has been added in the section on the peripheral nerves, and the relation of sciatica to rupture of the intervertebral disk is discussed. The author believes that a nucleus pulposus syndrome does exist, but very properly warns his readers against attributing all cases of sciatic pain to this lesion. Of the ultimate usefulness of such procedures as frontal leucotomy he is sceptical, and he deprecates newfangled terminology and the stressing of complicated and rare combinations of symptoms in neurology which serve more as a vehicle for the name of the physician who first described them than as a clarification of the mind of the practitioner who has to treat his patient.

This book has done and will continue to do much to bring the "mysteries" of neurology down to the general common-sense level of the rest of medicine, and is therefore much to be commended.

FOSTER HOMES FOR MENTAL PATIENTS

Foster Home Care for Mental Patients. By Hester B. Crutcher. (Pp. 199. $2.00 or 11s. 6d.) New York: Commonwealth Fund; London: Oxford University Press. 1944.

The use of foster homes for the care of various types of mental patients is by no means unknown in this country. The Lunacy Laws recognize the principle of single care supervised by the Board of Control. Mental defectives are boarded out, and the work of the foster home placement bureau of the National Association for Mental Health is well established. This activity has not, however, been developed by responsible authorities on any large scale, though such development may be required and demanded in the near future.

Hester Crutcher's book describes the methods and results of this work in America and especially in the State of New York, and it will be extremely useful to all those concerned with the project. Results are highly promising, as is shown by statistics of the returns to hospitals and release on parole of those placed in family care. The service is economically and administratively the responsibility of the hospital, but at least in some cases it is less expensive in terms of money than retention in hospital even of the non-recoverable quiet cases. The foster home is still more economical when regarded as a special form of treatment for recoverable cases, if it is compared with other treatments such as shock therapy.

The method of selection of patients and homes is carefully described, for on the success of this the whole service depends. The rival claims of the colony system, such as that of Gheel in Belgium and Dur-sur-Auron in France, and the district system, more favoured in the United States are discussed, and several illustrative case histories are given. Finally the forms and procedures used are illustrated.

Miss Crutcher is to be congratulated on giving a lucid, non-technical, and very readable account of the admirable service which she directs. This book should be on the reference shelves of all who are concerned with the mentally sick.

Notes on Books

Though this is not stated in a booklet called *Getting to Know your Baby*, by Dr. D. W. WINNICOTT (William Heinemann; 1s.), the six essays appear to have been broadcast talks. The author's particular views will not be accepted by everyone, but he has a quiet sincerity which demands respectful consideration.

Commended by Miss Florence Horsbrugh, the latest publication of the St. John Ambulance Association is *Child Welfare* (St. John's Gate, Clerkenwell, E.C.; 2s. 6d.), by Dr. HILDA M. DAVIS. In just over three hundred small pages she has packed a great deal of well-written and accurate information suitable for all those concerned with the care of children.

Preparations and Appliances

A TECHNIQUE OF DRILLING THE GLENOID IN BANKART'S OPERATION FOR RECURRENT DISLOCATION OF SHOULDER

Surg. Cmdr. P. B. **Moroney**, M.Ch.(Orth.), F.R.C.S., R.N.V.R., writes:

In 1923 for the first time Blundell Bankart described the displacement of the anterior rim of the fibro-cartilage, which enlarges the shallow glenoid cavity, as the essential anatomical lesion responsible for recurrent dislocation of the shoulder-joint. Again in 1938, reporting detailed operative technique and results of twenty-eight consecutive operations, he found no relapses and that full shoulder movements were retained.

For full service duties a secure shoulder is essential, and in the operative treatment of 27 patients, mainly sailors, Nicola's operation was abandoned following one early relapse. After changing to Bankart's exposure in the last eleven of these patients great difficulty in securing primary reposition of the capsule and cartilage flush with the anterior rim of the glenoid was experienced. This critical part of the operation requires the formation of two pairs of short, narrow canals in the bone margin and the introduction of two mattress sutures through them. Once accomplished, anchorage of the capsule to bone is easy. A sharp vulsellum worked through the bone, as described by Bankart, was not mechanically satisfactory in my experience; for the bone being remarkably hard the canal is apt to split by the rocking of the vulsellum forcing its passage, and there remains the difficulty of passing the suture through.

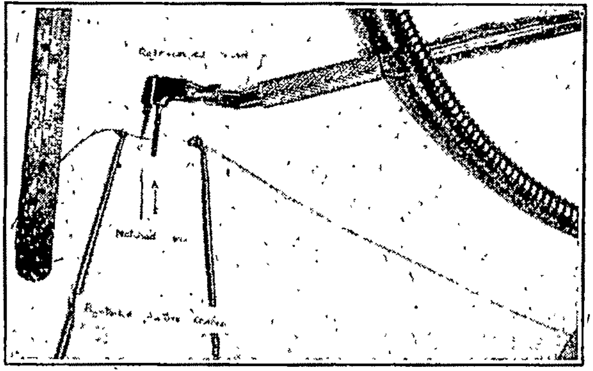

Fig. 1.—The assembled apparatus (motor not shown).

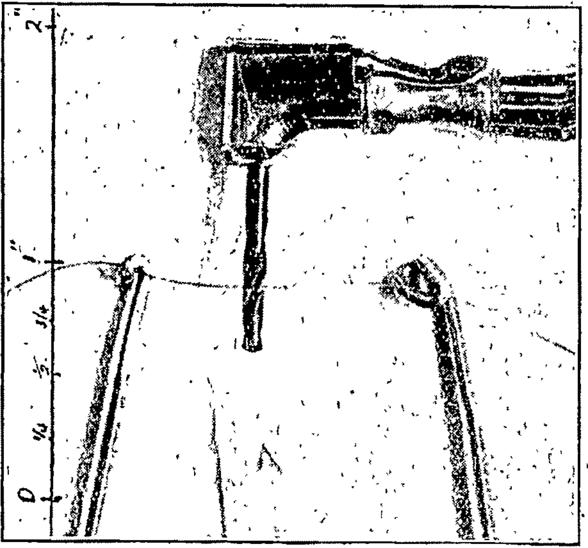

Fig. 2.—The slotted drill and pigtail guides. Scale of one inch as shown.

In the last seven operations the following apparatus has very considerably facilitated and hastened this part of the operation, which is performed after bony scarification. A right or contra-angled dental handpiece, coupled to the flexible driving cable of an electric motor, enables a short morse twist drill to be operated and directed in the depths of the wound (Fig. 1). The drill is made to the following specifications: when fitted to the handpiece its effective length is 3/4 in. and its bore 2/32 in. One quarter of an inch from the tip a slot, to a depth of a quarter of the circumference, is cut obliquely towards it at 45° inclination to the long axis of the drill (Fig. 2). A short, narrow canal is readily drilled, while an assistant, by strong outward leverage on the arm, clears the humeral head.

To engage a suture in the slot which on withdrawing the drill will pull it through, two guides are used, and make the operator independent of the direction of the face of the notch when the drill has come to rest. Pigtail-shaped, they are easily fashioned out of Kirschner wire. In use they render tense a very short length of suture material, which may then be depressed behind the drill and engagement in the slot follows. Pulling back (not rotating the drill) the handpiece takes the first suture end through a canal and with the other end the procedure is repeated (Fig. 3).

The cable has been autoclaved, but may be protected by a sterile calico sleeve. The remainder of the apparatus must be sterilized by heat, the dental handpiece being lubricated with sterile liquid paraffin before assembly. Unnecessary kinking of the flexible cable is avoided by placing the motor on its stand about 2 feet above the level of the operative field.

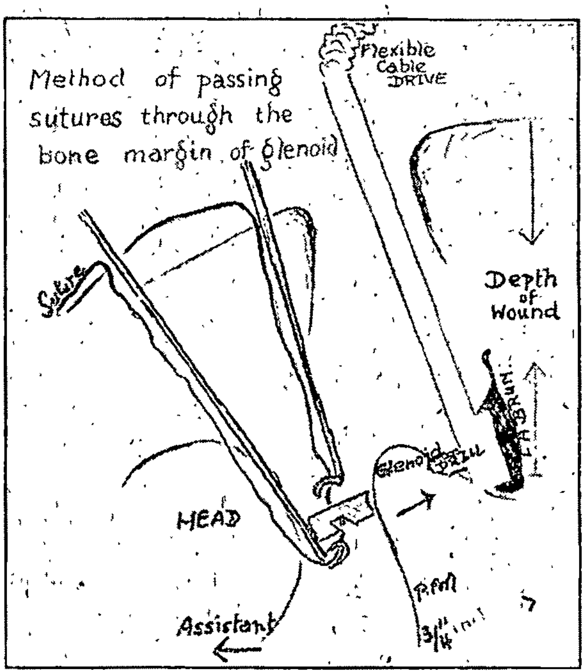

Fig. 3.—Juxta-articular bone has been scarified. A suture with the aid of guides is engaged in the slot and, using the drill as a carrier, is withdrawn mesially.

In all of the eleven cases the typical Bankart lesion was found, and in several a postero-lateral deformation of the humeral head could be visualized in the fuller exposure afforded by his arthrotomy.

The notched drills and pigtailed guides have been made for me by Messrs. Down Bros. Ltd. The remainder of the apparatus is standard equipment. I gratefully acknowledge the helpful suggestions of Surg. Rear-Adml. R. F. P. Cory, the practical advice on the dental coupling of Surg. Lieut.-Cmdr. J. Barnett Roberts, R.N.V.R., and the production of illustrative photographs by Sick Berth Petty Officers Lucy and Styles.

PROBLEMS OF AVIATION MEDICINE

The Oliver-Sharpey lectures by Dr. B. H. C. Matthews, printed in this and last week's *Journal*, on the physiological problems of flying are so clear and fascinating that we shall not attempt to make a précis or paraphrase; they should be read in their entirety. In general terms it can be said that men cannot fly above 20,000 feet without a supplementary supply of oxygen, or above 40,000 feet without a pressure suit or cabin. At 40,000 feet the pressure of the atmosphere is only one-fifth of that at sea-level. It might be thought that the flyer could overcome this disability by breathing 100% oxygen instead of the normal 21%, but matters are not so simple as this, owing to the presence of a constant pressure of water vapour and carbon dioxide in the lungs. In fact, at 50,000 feet water vapour and carbon dioxide will completely fill the lungs unless the aviator adopts the tactics of the submariner and surrounds himself with a pressure suit or a pressure cabin. The other limit to high flight is the occurrence of decompression sickness, or "bends," due to the formation of bubbles of gas in the body fluids and tissues when the atmospheric pressure is so greatly reduced. Finally, high flight is at all possible only if the body is protected from cold. At 40,000 feet the temperature of the air is −55° C., and destructive frost-bite occurs if the hands are exposed for more than a few seconds. The stratosphere airplane compresses the air to a pressure corresponding approximately to a height of 10,000 feet. It therefore corresponds with the pressure coil of a refrigerator and is a warm aircraft. The engineering difficulties are considerable, and the penalties of explosive decompression are obviously severe—sudden exposure to an atmosphere of lunar temperature and pressure.

There is no visible limit to the speed of flight, provided the airman is protected from the wind and the flight is level and sustained. Trouble comes only from rapid acceleration and deceleration, such as arise in catapulted take-offs, tight turns at speed or crash landings, or from rapid changes in the pressure in the middle ear when the aircraft is descending at speed. One of the most remarkable observations is the entire absence of symptoms when the body falls freely in space, as in delayed parachute jumps—i.e., jumps in which the parachutist allows himself to fall freely for a time before opening the parachute. The velocity ultimately reached is about 120 miles an hour. It had often been assumed in the past that a man falling from a considerable height became unconscious before he reached the ground; on the contrary, he is as comfortable physically as if he were resting in a hammock, and sensations of motion or air are curiously lacking.

Dr. Matthews's lectures are of special significance because they illustrate the value of co-operation between the physicist and the biologist. The physicist may calculate that an airman exposed to the centrifugal force of a tight turn may have an apparent weight of half a ton. It is for the biologist to visualize the effects of this pressure on the aorta and the vertebral column. The physicist has likewise illuminated our ideas about the mechanism of concussion of the brain and suggested better methods of prophylaxis. As man explores his environment in ever more fantastic ways, both through invention of mechanical devices and through the desire to work under every type of climatic condition, whether in deep mines or Arctic ice-fields or steaming jungles, it becomes more and more essential for the human physiologist to extend the range of his observations and to observe every aspect of the effects on the human organism of the extremes of heat, light, pressure, humidity, and so forth, and in this type of work the help of the physicist is indispensable. But many physicists would go further than this. They would say that the application of modern physical techniques to biological problems is likely to yield as rich a harvest as has already been reaped from the application of biochemistry to medicine. At present the application of physics to medicine is limited to radiology, the electrocardiograph, and the electro-encephalograph in diagnosis, and the somewhat empirical use of various forms of radiant energy in treatment; but it is highly unlikely that these represent more than a fraction of the contribution physics might make to human biology.

The value of co-operation between biologist and physicist may be mutual. A sports car has been defined as a car which combines the maximum of smell and noise with the minimum of comfort. A similar type of criticism can be applied to many of the inventions of the physicist and the engineer—that they leave the human element out of consideration. It is impossible, for example, to design a night-fighter aircraft or employ it to the best advantage without knowing something about the physiology and pathology of night vision. The idea is now generally accepted, but this has happened only recently, and there are many fields of applied physics and engineering to which it still does not apply. It must be constantly emphasized that any machine or apparatus which is to be used by men and women, whether in warfare or in industry, presents a biological problem which is at least as important as the problems of cost and mechanical efficiency—the applied physiologist must therefore be consulted through the various stages of design and application. Dr. Matthews also points out that the study of the physiological problems of the airman may yield knowledge of value in other fields. The clinical observer who has seen demonstrations of the effects on the human organism of abnormal tensions of the different atmospheric gases cannot have failed to be struck by the resemblance of the phenomena to those of mental disease. It does not seem unreasonable to suppose that morbid anxiety, depression, or elation may be due to variations in the concentrations of simple substances such as oxygen and carbon dioxide in the nerve cells, perhaps as a result of a metabolic defect or a break in a chain of fermentation reactions. In the past the study of brain chemistry has perforce had to be limited to isolated tissues or laboratory animals, but the experience which has been gained with the decompression chamber and the diving-bell suggests that similar techniques might prove fruitful in studying the psychological effects of changes in the metabolic condition of the human brain in health and disease.

During the war physiologists, clinical scientists, and psychologists have, by the urgency of the need, been drawn to work on the personnel problems of mechanized warfare. After the war this sense of urgency may diminish, and other problems may seem more attractive. The fine quality of the research carried out by teams such as Dr. Matthews's has been largely due to the fact that applied research was being performed by workers who had been trained in fundamental methods. The resultant acceleration in the advance of knowledge can be compared with the phenomenon of hybrid vigour; it is something that can happen only once in a generation. The research worker must return to his fundamental studies and his academic teaching to renew his strength. Yet it will be disastrous for this country if research on the problems of modern warfare peters out as it did in the decades between the two wars. There is little to suggest that the needs of civil aviation are sufficient to keep interest alive, any more than the needs of peacetime motoring are adequate for the study of the physiological problems of tank warfare. Interest in Service problems can be maintained only by emphasizing their dependence on fundamental issues and their link with work in other fields. For this reason it seems essential that the medical and physiological departments of the Services should maintain active communication with the civil research institutes, the universities, and the departments of industrial health research if they are not to take up hedgehog positions in the battleground of science, where mobile warfare should be the order of the day.

NUTRITION IN NEWFOUNDLAND

The high incidence of malnutrition in Newfoundland has long been a blot on our colonial administration. Presumably nutrition is nobody's business, and so little has been done to remedy the poor conditions in that island. The Government of Newfoundland has at last been moved to action by the Nutrition Council of the Newfoundland Medical Association, who recommended that a nutritional survey of the country be made. This was done last year, and the results have been recently published.[1] They make depressing reading. That the public health in Newfoundland is far from satisfactory is evident from the high infant mortality (107 per thousand live births) and the high prevalence of tuberculosis. Radiological evidence of active pulmonary tuberculosis was obtained in 7.2% of nearly 4,000 unselected individuals; calcified lesions were present in an additional 13.7%. While malnutrition is not the exclusive cause of these high figures, it undoubtedly plays a big part.

The diet consumed by the large majority of the inhabitants of Newfoundland is poor and monotonous, and the consumption of protective foods such as meat, eggs, milk, and vegetables is low. The only food that appears to be plentiful is fish. Assays of many of the foods eaten were made and the daily intake of essential nutrients calculated. These are given in the following table and compared with those recommended by the Food and Nutrition Board of the National Research Council, U.S.A. The latter figures have been adjusted to represent the requirements of the population as a whole.

Calories and Nutrient	Average Daily Consumption in Newfoundland	Daily Consumption Recommended by Nat. Res. Council, U.S.A. (adjusted)
Calories	3,000	2,544
Protein	94.4 g.	66.1 g.
Fat..	75.4 g.	—
Calcium	360 mg.	960 mg.
Iron	10 mg.	12 mg.
Vitamin A	1,146 I.U.	4,590 I.U.
Vitamin C	20 mg.	75 mg.
Vitamin B_1	0.96 mg.	1.45 mg.
Riboflavin	0.8 mg.	2.1 mg.
Nicotinic acid	14.6 mg.	14.5 mg.

With the exception of calories, protein, and nicotinic acid, all the figures fall short of the recommended intake suggested by the National Research Council.

All those included in the survey were examined clinically, with particular reference to scalp, hair, eyes, skin, lips, gums, tongue, and peripheral nervous system. The average person examined was somewhat slow mentally and lacking in initiative. This was particularly noticeable in the children, most of whom appeared apathetic and subdued, and in attitude and behaviour resembled little adult men and women. All subjects seemed older than their years. The skin of the children lacked elasticity and looked like that of adult men and women. "Staring" hair—i.e., dry, coarse, straight, and lustreless hair—was observed in 10% of the persons examined. The adults were, generally speaking, under weight, although the weight of the children did not differ appreciably from that of children of comparable ages in Canada and Britain. Muscular development was poor in both sexes at all ages, and prominent or winged scapulae were noted in many subjects. Minor stomach ailments and constipation were common. Dental caries was widespread, the condition in many of the subjects being indescribably bad. Anaemia, as judged by haemoglobin estimations, was present in approximately 20% of those examined. There was a close parallelism between the dietary inadequacies and clinical findings. Lesions characteristic of deficiency diseases were seen chiefly on the skin of the face, body, and limbs; on the lips, gums, and tongue; and in the eyes. Neurological signs, possibly due to deficiency of vitamin B_1 and riboflavin, were observed in 6.8% of the subjects examined. Of all the deficiency states noted, those associated with a lack of vitamin A, riboflavin, and vitamin C were the most frequently encountered. The principal manifestations of vitamin-A deficiency seen were xerosis, follicular keratosis, and xerosis conjunctivae. Frank scurvy was not seen, but the subscorbutic state, with swollen, bleeding, and unhealthy gums, was common. Dyssebacia, blepharitis, lacrimation, photophobia, angular stomatitis, cheilosis, and glossitis, all of which are stated to be diagnostic of ariboflavinosis, were observed in many of the subjects. Pathological tongue changes were present in over a third of the cases. These were not ascribed to nicotinic acid deficiency, for it was thought that the intake of nicotinic acid was adequate.

---

[1] Adamson, J. D., *et al.*, *Canad. med. Ass. J.*, 1945, 52, 227.

The report ends: "The poor nutritional status of the people of Newfoundland may well be in large part responsible for their impaired health and efficiency." The climatic and agricultural conditions form perplexing difficulties in the way of improving the nutritional status of the population. The land is poor, transport is lacking, and most of the people are engaged entirely in the fishing industry. At one time a third of the population were on the "dole," as there was not enough work. Measures to improve the nutrition of the people of Newfoundland are under way, but it must be emphasized that nutrition is a many-sided problem that cannot be solved by any single line of approach. Without help from outside, improvement in the nutritional condition of the island is impossible.

FIFTY THOUSAND MEMBERS

The British Medical Association now has more than 50,000 members. The 50,000 mark was reached last week for the first time in the history of the Association. The 50 men who constituted the Provincial Medical and Surgical Association in its foundation year, 1832, were certainly men of vision, and if we, their successors, have feelings of pride in the position the Association has now reached, we should remember with gratitude and admiration the pioneer wisdom of Dr. (later Sir) Charles Hastings and his colleagues who propounded "objects of the Association" which have stood the test of time. It may be of interest at this moment to quote from the last number of the *Midland Reporter*—the full title of which was the *Midland Medical and Surgical Reporter and Topographical and Statistical Journal*—in which the formation of the Association was announced:

> "The present Number completes the third volume of *The Midland Reporter*, and with it the Work under the above name will terminate: as the Editors can now congratulate themselves and the Public upon having attained the great object which they contemplated at the commencement of their arduous undertaking. Their appeal to the public spirit, generous feelings, and pure love of Science, which so extensively pervade and dignify our noble profession, has not been made in vain. A wish has, in consequence, been warmly expressed and widely circulated, that the members of the profession residing in the Provinces should unite themselves into an association *friendly* and *scientific*; that this Association should have for its main object the diffusion and increase of Medical Knowledge in every department of science and practice, and that the valuable communications of its Members should, from time to time, appear in the shape of published Memoirs of the Society."

The *Reporter* gave way to the annual *Transactions* of the newly formed Association, but found its true periodical successor in the *Provincial Medical and Surgical Journal*, which appeared in 1840, the title of which was changed in 1853 to the *Association Medical Journal*, and again in 1857 to the *British Medical Journal*.

The Association was founded in the year which saw the passing of the first Reform Bill and the first of the four epidemics of Asiatic cholera which swept over this country during the nineteenth century. Of the five objects of the Association given in the prospectus of May, 1832, the first four can be summarized in these key phrases: (1) "Collection of useful information"; (2) "Increase of knowledge"; (3) "Investigation of . . . endemic and epidemic diseases"; (4) "Advancement of medico-legal science." The fifth embodied "the maintenance of the honour . . . of the profession . . . by promoting voluntary intercourse and free communication of its members, and by establishing the harmony and good feeling which ought ever to characterize a liberal profession."

The year 1946 may prove to be another great year of reform, which this time may vitally affect the medical profession. So long as the reform preserves the principles that "characterize a liberal profession," medical men and women will pursue their traditional aims and objects with "harmony and good feeling." The numerical strength of the B.M.A. is now such as to enable it to pursue its objects in full consciousness of its strength. How this strength has grown since the foundation of the Association is shown in the following table of membership.

1832	 50	1906	 20,993
1836	 500	1925	 30,524
1839	 1,010	Sept. 2, 1939	... 39,121
1873	 5,400	1942	 41,239
1883	 10,050	July, 1945	... 50,032
1895	 16,000		

HISTOPLASMOSIS

Histoplasmosis, described first by Darling in 1905, is a mycosis affecting primarily the cells of the reticulo-endothelial system. The parasite, *Histoplasma capsulatum* Darling 1906, a small capsulated yeast-like body, 3 to 4 μ in the longer diameter, occurs in great numbers within the reticulo-endothelial cells, which are stimulated to hyperplasia. The granuloma formed tends to undergo central necrosis and provoke a peripheral fibrotic reaction. During the 20 years after Darling's discovery[1] of the first three cases in Panama in 1905–6 no further record of the disease appeared until Riley and Watson[2] described a case in the United States in 1926, and their report was followed quickly by others. DeMonbreun,[3] in 1934, reported his success in cultivating the fungus, and, with this additional means of diagnosis and the developing interest in mycoses, the number of cases reported annually in the United States greatly increased, and the disease was found in Argentina, Austria, Brazil, Central America, England, Mexico, the Philippines, and Rhodesia; this increase seems to be attributable to greater accuracy in diagnosis rather than to an actual increase in incidence.

The disease occurs sporadically and attacks persons of all ages; about 18% of the patients have been infants under 1 year old, and one patient was aged 71. There is no apparent seasonal incidence and no known occupational predisposition. Nothing is known of the source of infection. The fungus has never been found vegetating saprophytically in nature, but the disease has been identified on four occasions in the dog, and yeast-like bodies resembling *Histoplasma* have been seen in the tissues of the mouse,[4] the rate,[5] and the ferret.[6] The mode of infection is unknown, but it is thought that the fungus may gain entry through the lungs, the alimentary canal, or the skin.

[2] *Amer. J. trop. Med.*, 1926, **6**, 271.

[3] Ibid., 1934, **14**, 93.

The disease may attack one or several organs or tissues of the body, and all have been involved in some case or another. The symptoms and clinical features depending upon the distribution of the lesions, there is no characteristic symptomatology. Ulcerative granulomatous lesions of the lips, tongue, and other mouth parts, nose, pharynx, larynx, and intestine, may simulate tuberculosis or even malignant disease. Local or general enlargement of the lymphatic glands and the spleen may suggest leukaemia or lymphadenoma. Involvement of the lungs, especially in the form of miliary granulomata, has frequently led to the diagnosis of tuberculosis, while histoplasmosis of the adrenals may be reflected, clinically, only in the signs of adrenal insufficiency, and involvement of the bone marrow in anaemia. Three cases are on record of vegetative endocarditis, affecting the auriculo-ventricular valves, caused by *H. capsulatum*. In the majority of cases irregular fever, sometimes with chills and rarely with night sweats, develops in the later stages of the disease. The diagnosis, therefore, cannot be based on symptomatology, but depends upon the identification of the parasite in culture or in microscopical preparations from the lesion. The most suitable material for this purpose is tissue taken by biopsy from lesions of the skin or mucous membranes or superficial lymph nodes. Smears of the peripheral blood in the final stages of the disease, or of the sternal bone marrow, may contain the parasite, free or in phagocytic cells; but its occurrence is not so frequent as to make these examinations alone of much value in diagnosis. The best stains for demonstrating the parasite in morbid material are haematoxylin, Giemsa's stain, the Claudius modification of Gram's stain, and Masson's trichrome stain. Isolation of the fungus in culture is not difficult, but the development is slow and may take from eight days to three weeks. The fungus, in saprophytic life, is dimorphic; cultures incubated at 37° C. on blood agar and certain other media vegetate as a simple yeast resembling the parasitic form, but at room temperature the fungus vegetables in a mycelial form with a profuse aerial growth bearing terminally on short branches the characteristic piriform to spherical chlamydospores measuring from 3 μ to 15 μ in diameter, and having on the surface numerous prominent tubercles or finger-like processes. If, because of gross contamination of the tissue, direct cultivation is impracticable, it may be isolated by inoculation of the material into a susceptible animal such as the mouse, rat, or guinea-pig. A possible aid to diagnosis may be developed in tests of dermal hypersensitivity to filtered extracts of cultures of the fungus.

The prognosis is bad, for the disease is almost inevitably fatal, the duration being reckoned in months or even weeks. All forms of treatment have given disappointing results, but radiotherapy and the use of some pentavalent antimony compounds may prove helpful in early and localized superficial infections. In assessing the value of treatment, however, the possibility of spontaneous improvement should not be overlooked; in the second English case the patient was alive and in apparently good health two years after conclusive diagnosis.

HELP FOR THE DEAF

As announced in our news columns this week, a deafness clinic has recently been set up at the National Hospital, Queen Square, where it is proposed to investigate and treat by means of hearing aids and other methods all forms of deafness, excluding those accompanied by active otitis media with ear discharge. The Otological Research Unit which is being established by the Medical Research Council at Queen Square will be under the direction of Dr. C. S. Hallpike, aural physician to the National Hospital and a member of the Medical Research Council's scientific staff and of its Electro-acoustics Committee.

Through its committee on the physiology of hearing the Medical Research Council has for some years been concerned with the problems of deafness, and in order to probe further into this distressing complaint it has recently formed three research committees—one to deal with the medical and surgical problems of deafness, the second to consider the design and performance of electro-acoustic equipment, and the third to look into the education of the deaf. Recent correspondence in this *Journal* has made it clear that the provision of a suitable deaf aid at a reasonable cost and with easy maintenance is an urgent need among those whose deafness could be relieved in this way. The clinic at Queen Square, under Dr. Hallpike, is to examine this very question as part of the work of the M.R.C.'s Electro-acoustic Committee, and for this purpose needs as many deaf subjects as the clinic can deal with. Patients so investigated will of course have the advantage of expert advice and treatment, and practitioners, therefore, will be helping both them and the clinic if they refer to it their patients who require relief. Those wishing to take advantage of this should write to the Director, the Otological Research Unit, National Hospital, Queen Square, London, W.C.1.

THE I.A.M.C. JOURNAL

A new medical journal is nowadays something of an event, and when it comes off those with designs of their own murmur sadly, "I wonder where they got the paper from." The first number of the first volume of the *I.A.M.C. Journal* which has just reached us is, however, not published in this country but from the headquarters of the Indian Army Medical Corps at Poona. It appears in a handsome maroon cover with the badge of the I.A.M.C. attractively displayed in the centre of the page. Our first envy of the paper is diminished on finding that there are to be only two issues yearly—an unusual frequency in medical journals. The present and first number appears with a note of inauguration from Lieut.-Gen. Gordon Wilson, Director of Medical Services in India. "For the first time," he writes, "in the history of military medical organization in India we have a Medical Corps in which officers, warrant officers, N.C.O.s, and men have become unified. This is a great achievement full of the highest promise. . . . It is fitting that this unification should be symbolized by a journal, and we wish the Editor, Colonel D. R. Thapar, all success."

The contents of the first number suggest that the *I.A.M.C. Journal* combines the virtues of a scientific with those of a well-produced hospital gazette. It has photographs of various members of the I.A.M.C., including one showing Lord Louis Mountbatten shaking hands with an Indian orderly. We note with interest a short article written in Basic English, and that a group of instructors in the Army Medical Training Centre have been learning this linguistic system, so as to be able to spread knowledge of the English language among their Indian colleagues.

A TROPICAL DIETARY

BY

W. E. McCULLOCH, M.D.

(*Kingston, Jamaica*)

The dietary below was drawn up by me and accepted by the Nutrition Committee of the B.M.A. in Jamaica as an immediate target at which to aim for the population of the country, which is essentially an agricultural labouring community. With the committee's permission it is now submitted for comment, as it is felt that a quantitative minimal basic dietary based on tropical foodstuffs should be worked out as a guide to medical personnel in these areas.

The Position in Jamaica

We have recently had the pleasure of a visit from Dr. Platt, who is the adviser on nutrition to the Secretary of State for the Colonies. It has proved a great stimulus to us, and his standards for an immediate aim in nutritional policy have been accepted. The standards are included at the bottom of the table. The committee was set up at the invitation of the Agricultural Policy Committee for Jamaica, which sits under the chairmanship of Mr. John Wakefield, the Inspector-General of Agriculture in the West Indies, and among the terms of reference was the question whether Jamaica can produce all the foodstuffs necessary for a balanced diet.

Item (Edible Portions)	Amount		Calories	Protein (g.)	Ca (mg.)	Fe. (mg.)	Vitamins				
	Oz.	Grammes					A (i.u.)	B_1 (mg.)	B_2 (mg.)	Niacin (mg.)	C (mg.)
Cereals:											
Wheat flour, 70%	4	125	439	12·5	20	2·5	0	0·07	0·06	1·25	0

Totals			2,822	70·85	555·3	24·45	16,339	1·98	1·38	18·47	96·4
Dr. Platt's standards			2,500	50–60	800	15	8–9,000	1·20	1·20	12–15	30

The main deficiencies in the Jamaican dietary at present, in the order of their importance, are protein, riboflavin, niacin, thiamine. It was found, using the Hot Springs Plan I as a yard-stick, that Jamaica would require over three million acres to feed herself on her present system of food production, even when half the cereal needs were met by importing wheat flour. The total cultivable land is given in the census as being about 700,000 acres.

It had to be borne in mind that the export crops must increase if Jamaica's economic position is to improve. The necessary corollary was the recommendation that there should be a complete revolution in the agricultural policy of the island and that the slopes of five-sixths of the country should be devoted to grass culture in the main, with a rapid expansion of the stall-fed dairy cow and small stock. Intensive mixed farming seems to be the only hope of the island.

During his visit to Jamaica Dr. Platt proposed a diet scale which would measure up to his standards by the addition of food yeast, calcium carbonate, and ferrous sulphate to the 70% wheat flour. I am still as much a believer in natural foodstuffs as ever, and accordingly the suggestion was not incorporated in the diet.

Comments on the Dietary

The following comments on the dietary are self-explanatory.

Cereals.—(*a*) Your committee considers that whole wheat should be imported and the milling done in Jamaica. Wheat offals are necessary for the production of small stock and milk. The recommendation of white flour is temporary. (*b*) We hope that the rice requirement will be met to the fullest possible extent by local production. (*c*) Only yellow maize should be grown, because it gives valuable vitamin A in large amounts. (*d*) The various sorghums are not mentioned. Their high digestibility is to be remembered. The "victory rice," which is a local sorghum product, was very popular with school-children, to whom one of us fed it for two school terms, and their general health improved. The development of these grains, especially dwarf guinea corn and pearl millet, should be pushed for both man and his animals.

Starchy Roots.—If there is not a constant supply throughout the year the calorific value of the diet will drop seriously. The large amount of vitamin A expected from yellow sweet potato is to be noted.

Pulses.—Beans, peas, peanuts, and soya beans can be regarded as the "poor man's meat" and must be pushed. An immediate improvement in the supply of first-rate protein is to be expected from these crops while meat production is being developed.

Meat or Fish.—Immediate improvement is to be looked for in the rapid development of small stock. We would stress the value of pork because of its quick production rate, high calorie (energy) content, and richness in vitamins B_1 and B_2.

Oils.—On the diet as submitted there is no necessity to have the oils and fats fortified with fat-soluble vitamins.

Sugar.—One pound a week is ample as a flavouring. The increased cereals and roots are the basic sources of carbohydrate energy.

Vegetables.—(*a*) *Green leafy and yellow* will not be eaten up to the ration without widest publicity. Although there is a good deal of "back-yard" cultivation, the total requirements will not be met by this method alone, and these vegetables must also be grown as field crops. (*b*) *Citrus:* One orange or half a grapefruit is a unit which can be handled easily. (*c*) *Other vegetables and fruits:* Our estimate is absolutely minimal. The large mango crop and the bananas and breadfruit are not calculated. They add considerably to the total, but their seasonal incidence precludes their inclusion in a daily ration. Bananas will be exported and not eaten (as before the war). The value of guavas, green peppers, pawpaw, and the avocado pear should be widely publicized.

Milk.—As an immediate target we recommend only one-fifth of the Hot Springs standard. The butter value of the milk is quite unnecessary in the present diet, and so we advocate the erection of creameries to extract the butter for export and the use of dried skimmed milk in the ration. No expansion of the manufacture of condensed milk should be permitted, as this island must find export crops, and butter would be no loss to the dietary of the people if it were manufactured and exported. In the first instance the skimmed milk should be used in giving children a midday drink, with two biscuits. One ounce of dried skimmed milk per child is recommended.

Molasses or Wet Sugar.—This is necessary for its iron content. In a tropical country which is full of parasitic diseases iron is probably the most important mineral constituent of the dietary, and the rich available iron in molasses should not go to waste. We recommend that the biscuit for the mid-morning snack should be made to contain at least one drachm of molasses. Expectant and nursing mothers should also be able to get these biscuits.

Calcium.—We are not afraid of the small amount in the dietary. In this country of sunshine there can be no lack of vitamin D, and so we assume maximal absorption of this element. As the diet supplies ample phosphates there will be the maximal utilization of these substances, and 100 mg. in excess of minimal maintenance requirements will be adequate.

EAST OF SUEZ*

BY

GEORGE R. McROBERT, C.I.E., M.D., F.R.C.P.

Lieut.-Col., I.M.S.; Professor of Medicine, Madras Medical College; Physician, Madras General Hospital

[In his opening remarks the lecturer appealed to newcomers to the medical Services in India to readjust their mental outlook, to take a keen interest in the country, and to acquire a knowledge of its current problems. He stressed the importance of providing occupational or diversional therapy for soldiers who were in hospital, even if only for a few days, in a strange land without possibility of visits from friends and relatives. It would be found (he said) that the diseases of the temperate zones were all present there, practically always with protozoal, helminthic, and fungous infections superadded to make diagnosis and treatment more complicated and medical practice more interesting. Dietetic difficulties also played their part. It would be learnt, too, how very localized disease or strains of disease could be. The lecturer then proceeded to give an account of the most important diseases met with.]

Malaria

The most urgent essential for the newly arrived doctor in the Orient is to get a thorough understanding of the symptomatology and treatment of malaria. The principal fact to be grasped is that the parasite of "killing tropical malaria"—malignant tertian—does not sporulate in the blood circulating in the vessels at the surface of the body as do the other species of malaria parasites, but, instead, multiplies asexually in the capillaries of the vital organs in the depths of the body, producing glutinous agglomerations of pigmented masses of dividing protoplasm which act most effectively as multiple emboli, giving rise, in accordance with the locality of the sporulation, to symptoms which may simulate those of any acute disease, *febrile or afebrile*, of any vital organ. Thus, sudden coma, hemiplegia, precordial distress, "renal colic," appendicitis, and choleraic diarrhoea with severe collapse may all be attributable to sporulation of *Plasmodium falciparum*.

When, therefore, symptoms which may be ascribed to the action of that parasite present themselves, steps should be taken to examine a blood film and a thick drop; but even if parasites are not found, quinine or its equivalent should be given by an effective method if it is at all possible that malignant malaria is the cause of the symptoms. *Per contra*, it is also necessary to realize that the mere finding of malaria parasites in the blood does not complete the diagnosis if there are unusual symptoms, and one must constantly be on the watch for such conditions as meningococcal infections, which may occur along with malaria. A golden rule in connexion with cerebral or meningitic symptoms is, "When in doubt, perform a lumbar or cisternal puncture."

I shall not enter into controversial matters with regard to treatment except to say that, although the intramuscular route for the administration of quinine is grossly abused in India, it still has its uses in fat persons, women, and many children. Some experienced observers prefer the intramuscular route to the intravenous even in acute emergencies, fearing an unduly swift liberation of malaria toxins; yet I have seen nothing but benefit result from small doses of quinine given intravenously, very slowly and highly diluted. If quinine—or emetine, which has also a necrosing effect—is to be given intramuscularly, special precautions should be taken in sterilizing the skin and syringe. I myself never delegate such preparation to a nurse or technician.

Amoebiasis

Next to malaria the chief source of pitfalls for the unwary or uninstructed is that protozoal mole the *Entamoeba histolytica*, which spends the greater part of its life burrowing and nesting in the depths of the bowel wall, far down in the submucous tissue, where it produces a profuse gelatinous degeneration. Like a mole under a lawn, it comes to the surface here and there, piling up little hillocks of material from the summits of which it peeps forth; it emerges when there is no danger, but remains resolutely below when there is the slightest hint of unfavourable conditions on the surface. It is a tissue parasite, not a surface invader like the dysentery bacillus, and from its deep and tortuous lair it is difficult to eradicate. This protozoon readily wanders off into venous channels, forming embolic deposits in other parts of the body, notably the liver, lung, and brain.

The proper treatment of intestinal amoebiasis is time-consuming and tedious, but it is well worth while, in primary infections, to make your patient submit to a full course of treatment, which entails absence from duty for six weeks—the first three weeks strictly in bed.

In permanent inhabitants of the Tropics much temporary patching up has to be done, but a high proportion of success can be attained in primary cases from the type of long treatment recommended by Manson-Bahr (1943), in which every therapeutic weapon is used in turn, by mouth or injection, over a period of several weeks, combined with retention enemata of yatren or allied preparations after a morning colon washout with weak sodium bicarbonate solution. A relatively liberal diet may be given throughout the treatment, and the results should be checked by sigmoidoscopy. The absence of amoebae and cysts in a specimen is valueless as an indication of cure if any treatment has been given during the past 14 days, even sodium bicarbonate in moderate doses by mouth three times a day being sufficient to cause the amoebae to skulk in their burrows.

Chronic intestinal amoebiasis is a much more common cause of minor bowel disturbances and an "out of sorts" feeling than is generally realized. It does not necessarily produce frank blood and mucus in the stools; but, as Hamilton Fairley pointed out years ago, a mild latent amoebic infection may so upset haemopoiesis as seriously to interfere with the treatment of anaemia of some other origin. Do not forget to examine with the microscope the stools of patients who are below par for no apparent reason.

Our surgically minded friends require special warning. Never operate for appendicitis in the Tropics without eliminating the possibility of intestinal amoebiasis; a faecal fistula so often results from such an operation. Similarly, cancer of the colon and rectum and hypertrophic tuberculous disease of the caecum may be so closely simulated by enormous single amoebic lesions that the possibility of such a protozoal cause must be kept in mind. We who live and practise in the Tropics, on the other hand, need constant reminders that blood and mucus from the rectum do not necessarily indicate dysentery.

Amoebic liver abscess should not occur in military personnel, as we have the means of aborting it in the stage of pre-suppurative amoebic hepatitis, but when it does occur open operation is rarely required nowadays—aspiration by Potain's aspirator or three-way syringe, after injection of emetine intramuscularly on three successive days, giving the necessary relief of tension, which must be followed by a vigorous and complete anti-amoeba campaign. A number of sufferers from amoebic abscess of the liver deny a history of dysentery, and it is quite common to be unable to demonstrate the parasite in the motions of sufferers from amoebic abscess.

Any lump in the abdomen, movable or immovable, with or without pyrexia, and even in the absence of leucocytosis, may be a hepatic abscess. All lesions at the base of the lung, especially on the right side, with or without a history of dysentery or hepatic involvement, may be amoebic in origin; the effect of emetine in such cases is striking.

Emetine is a valuable therapeutic weapon, but is a cardiac poison and cumulative nerve poison. During its administration the patient should rest in bed, and if he proceeds to a hill station, as so many military patients do after emetine treatment is over, very strict instructions must be given with regard to the dangers of over-exercise at high altitudes. Above all, the subject of amoebic hepatitis and amoebic abscess must eschew the use of concentrated alcohol: short drinks, gin-and-bitters, etc., have a demonstrably bad effect on such subjects.

---

* A summary of lectures delivered to E.C. officers of the R.A.M.C. and I.A.M.C. under the auspices of the Madras Branch of the B.M.A., 1942-4.

Very few women suffer from amoebic damage to the liver, and those who do are often found to be overfond of cocktails.

Bacillary Dysentery ; Simple Diarrhoea

Much has been written of late on the treatment of bacillary dysentery. A dose of castor-oil emulsion as soon as symptoms start, with a single 2-g. dose of a soluble sulphonamide, followed by regularly repeated doses of the relatively insoluble sulphaguanidine, gives satisfactory results. I myself continue to use collosol kaolin and belladonna along with the modern sulphonamide therapy. Serum therapy is reserved for highly toxic cases.

There are many causes of simple diarrhoea in India. The worst possible treatment is ordinary sedation by a derivative of opium. Finely divided kaolin forms one of our best remedies, and is generally included in the essential baggage of experienced touring officers. I am in hearty agreement with Hurst's suggestion that natural achlorhydrics should not be sent to the Tropics. It is too much to expect that in time of war every soldier should submit to a test meal before sailing, but the fact remains that achlorhydrics suffer from lack of the natural antiseptic barrier in the pyloric antrum, and that even those with low acid curves are particularly prone to intestinal complaints, especially in the hills.

Filariasis ; Lymphogranuloma Venereum ; Leishmaniasis

The new arrival usually has a very hazy notion of the effects of filarial infection. Gross manifestations of chronic filariasis are to be seen at every street corner, but elephantiasis occurs in a relatively small proportion of cases of infection. In many apparently healthy persons microfilariae are to be found in the blood at night, but in persons over 40 years of age an attack of filarial fever once or twice a year is not unusual. In a large hospital in which I have worked over 50% of the senior staff were absent at least once a year for a few days on account of filarial fever with lymphangitis. Even among healthy athletic young medical students here about 1 in 15 has a filarial hydrocele. Minor manifestations of filariasis should be no bar to recruitment, but the possibility of retro-abdominal lymphangitis and adenitis of filarial origin must be borne in mind in the case of personnel from filarial homes who are stricken with acute abdominal symptoms accompanied by high fever.

You ought to take the earliest opportunity of visiting a civil hospital and of seeing examples of lymphogranuloma venereum with its resultant ano-rectal syndrome and of that appalling condition, ulcerating granuloma of the pudendum with its spreading and corroding ulceration at the muco-cutaneous junctions.

Leishmaniasis, both dermal and visceral, is common in certain parts of India, though the two forms are never, so far as I know, together in the same place. The early diagnosis of the visceral variety (kala-azar) is by no means easy, and it is not unusual for several months to elapse before a diagnosis is made. Culture, on a special medium, of material obtained by sternal puncture is the best early method of certain diagnosis. The disease should be suspected in any case of apparently non-toxic fever with no physical signs after three weeks have elapsed without improvement. Leucopenia with a high relatively large mononuclear count often points the way to a diagnosis. The aldehyde and urea stibamine serum tests, which depend on gross alterations in the relative serum albumin and globulin ratios, are of value only after some months have elapsed since the onset of the initial fever.

Fevers

Typhoid fever you will meet everywhere. Every town and village acts as a reservoir of virulent strains of *B. typhosus*. Repeated inoculation is of great value as a preventive measure: it acts as a strengthening of the guard and not as an absolute defence against invasion by an overwhelming force. Do not, therefore, rule out the possibility of enteric fever because of recent inoculation. Remember that the earlier blood is taken for culture the more likely is the result to be positive; and, despite recent advances in technique in performing the Widal agglutination test with pure antigenic material, it is well to remember that the actual sight of a tiger is better proof of its presence than the mere demonstration of pug marks in the jungle. Always prefer cultural to agglutination methods for the diagnosis of typhoid.

I have had occasion to draw attention to the great importance of the administration of large quantities of fluid to patients suffering from fever in hot climates (McRobert, 1941). This applies to typhoid patients particularly, and every effort must be made, by continuous rectal drip if necessary, to ensure replacement of water lost by evaporation. You will find that care paid to the supply of an adequate amount of drinking-water will cut down the rate of sickness from heat exhaustion, and the addition of small quantities of common salt adds to its beneficial effects.

Attention must also be drawn to the wide prevalence of tropical typhus, carried by mite, tick, and flea. Its existence on an important scale over the whole of the Tropics has only recently been recognized. The hetero-agglutination reaction associated with the names of Wilson, Weil, and Felix, which we used for the diagnosis of louse typhus in the last war, has been suitably modified by the use of new strains of *B. proteus* for the detection of tropical variants of typhus.

Sandfly fever and dengue fever—the latter with its almost intolerable pains and morbilliform rash—are often looked upon as mere minor curses of India, as no one ever dies of them; but both are very exhausting and debilitating diseases, both give rise to states of severe depression—not infrequently with suicidal tendencies—and it is not unusual to find that the onset of some serious diseases such as pulmonary tuberculosis dates from an attack of dengue fever. Medical officers must take the greatest care to see that convalescents from these diseases are not returned to duty until they have fully recovered.

Helminthic Infection ; Taeniasis

Of the dangers of intestinal helminthic infection you have heard much. You are aware of the prevalence of hookworm disease and of the very satisfactory methods available for its treatment. You should note, however, that intestinal *Ascaris* infection may attain such a degree in some patients that symptoms of intestinal obstruction are produced.

You may not be aware of the grave danger to the carrier and his friends from infestation with *Taenia solium*. Somatic taeniasis is a terrible condition often leading to the mental hospital, and vigorous treatment after absolute starvation for three days is advisable in any intestinal infection with that worm. Avoid Indian pork and sausages like the very devil.

Conclusion

You who have come newly to India have much to learn; each of you has a glorious field of exploration ahead. You have the satisfaction of knowing that to a much greater extent than in the West the health and well-being of your men and the efficiency of the battalions depend on the keenness and ability of the medical officers. Those of you who go home again will have acquired a priceless familiarity with laboratory methods in the diagnosis of disease. Doubtless some of you will decide to remain, for having

> " 'eard the East a-callin' you won't never 'eed naught else."

Manson-Bahr, Sir P. (1943). *The Dysenteric Disorders*, Cassell and Co., London.

The Tata Memorial Hospital in Bombay for the treatment of cancer and allied diseases has issued its first triennial report, covering the years 1941-3. This hospital, which owes its genesis to the munificence of the late Sir Dorab Tata, of Bombay, is the last word in modern hospital construction. Originally visualized as a radium institute, its scope was enlarged to include treatment and facilities for research in cancer. The chief aim of the hospital, therefore, as its name implies, is the study of cancer along the channels of histopathological and biochemical investigation, and this can best be accomplished by the team work of specialists who are so actively and so constantly in contact with the disorder that the facts concerning it become more readily recognizable. The hospital was opened in February, 1941, and in this report, which covers the work done since then, there is evidence in the carefully compiled analyses of the first 5,000 cases that it will fulfil its purpose. While the plans for the hospital were maturing, Indian students and doctors were sent abroad for special training, and now hold appointments on the staff, which is manned entirely by Indians under the administrative superintendence of Col. Sir J. N. Duggan, I.M.S.

LONDON'S HOSPITAL PROBLEMS

A REPORT BY THE KING'S FUND

The promise of a further report, prepared jointly by King Edward's Hospital Fund and the Voluntary Hospitals Committee for London, on some post-war problems of the hospital services in London and the Home Counties was the chief item of news in the address by the chairman, Col. CLIFTON BROWN (Speaker of the House of Commons), at the annual meeting of the King's Fund last week. He said that the movement towards a comprehensive hospital service, already evident before the war, had taken on a new momentum with the White Paper issued by the Minister of Health and with the survey of hospital services in London and the Home Counties. The report would be primarily concerned with the part to be played by the voluntary hospitals, but it was hoped that in some respects it might prove not unhelpful to the L.C.C. and to the other local authorities upon whom fell such a heavy share of the hospital burden. Col. Clifton Brown referred to two reports recently issued by the Fund. The Committee on Hospital Diet, of which Sir Jack Drummond was chairman, had followed up its 1943 report by a more detailed and comprehensive one.* Over 60 hospitals, he said, had already taken advantage of the expert advisory service, and in many hospitals, both in London and elsewhere, the catering arrangements had been overhauled and brought into line with a more modern outlook on nutrition —so far, at least, as the prevailing shortage of dietitians, cooks, and other skilled staff permitted. The other report, on standards of staffing, gave guidance to hospitals on the number of nursing staff needed, and on the factors which had to be taken into account in arriving at this figure. It had been prepared by a subcommittee of the Distribution Committee under the chairmanship of Dr. Morley Fletcher. It sprang from a conviction that the shortage of nursing staff would never be overcome until the understaffing, which the subcommittee regards as affecting almost every hospital, had been remedied, and that a start could be made only by those hospitals which were in a position to attract enough recruits. More parents would encourage their daughters to become nurses were it not that the nurse's life was generally considered hard and exacting.

Dr. H. MORLEY FLETCHER, presenting the report of the Nursing Recruitment Committee, said that during 1944 it became increasingly evident that over the country as a whole the supply of recruits was gravely inadequate for the needs of the hospitals. The "wastage rate" of those who left without completing their training had risen steeply during the war and was now excessive. It was therefore more than ever important to supplement the recruitment work of the individual hospitals by centralized recruitment.

The report of the Emergency Bed Service Committee showed that in the first six months of last year 2,766 cases were dealt with, as against 1,874 for the corresponding months of 1943, but in June the flying-bomb attacks started and the abnormal conditions during the remaining months of the year resulted in a decrease of over 1,200 cases. There was a great variation in the extent to which doctors availed themselves of the service, and it was when there was a general shortage of beds that the service was busiest.

In moving the report of the Diet Committee, Sir HUGH LETT referred to the institution of refresher courses at the London Hospital for those concerned with hospital catering. There were a large number of applications for admission to these courses, but unfortunately the work was cut short by enemy action after two courses had been held. It was hoped, however, to resume them after the vacation.

The income of the Fund was well maintained during 1944. Legacies amounted to just over £50,000, and the receipt of £50,000 from Lord Nuffield's Trust for the Special Areas made it possible to transfer all but £1,800 of the receipts from legacies to the general funds. This year £75,000 has been received from the same source.

USE OF THE TITLE "NURSE"

After Oct. 15 it will be an offence to use the title "nurse" unless the person doing so is a State-registered nurse or an enrolled assistant nurse, and agencies supplying nurses must be licensed by local authorities and must supply only those who are State-registered nurses, enrolled assistant nurses, midwives, or members of other classes to be prescribed. The Minister of Health and the Secretary of State for Scotland have thus, by Orders issued last week, given practical effect to the intention of Parliament in the Nurses Acts of 1943 to restrict the use of the title "nurse" and to govern the licensing and control of agencies for nurses. There is to be an exception for children's nurses, who may use the term unless circumstances suggest that "they are something other than children's nurses," and other permitted usages are "trained nurse" by those on the general part of the nurses list, "maternity nurse" by midwives, and "student nurse" and "pupil assistant nurse" by those in training for State registration and for the Assistant Nurses' Roll. The object of these Orders is to protect the public against the use of the term "nurse" by persons having no nursing qualification and against the risk of being supplied without their knowledge with the services of unqualified persons at possibly high fees. Regulations also prescribe the form in which applications for licences for agencies are to be made, the fee to be paid—two guineas for a first application, one guinea for a renewal—and the form in which agencies must notify the nurse's qualification to the person employing her.

EVACUATION OF CASUALTIES BY AIR

On the invitation of the Director-General of Medical Services, Royal Air Force, a preview was given in the British Council theatre of a film illustrating the evacuation of casualties by air. The film, which lasts about half an hour, is intended primarily for the training of air-ambulance orderlies. The disposition in the aeroplane of stretcher cases and folding-chair cases is decided with a view to the attention which the more serious cases may require *en route* and to rapid exit on arrival. The film showed the extraordinary attention which is paid to the detail of stores and equipment—the provision for first aid, the penicillin drip, the oxygen equipment, the apparatus for giving morphine, as well as hot-water bottles, flasks for hot drinks, bed-pans, and so forth. Having landed and evacuated their casualties the orderlies must replace whatever has been taken out of store. The system of cards in triplicate whereby a record of each case is retained and transmitted was also shown. The film demonstrated the high level to which this transport of the wounded has been brought, and how comfortable, rapid, and safe it can be. "Speed without hurry" is the motto for the men and women orderlies employed. On one detail the film might give a wrong impression. It showed patients smoking cigarettes in the aircraft; this occurred during certain phases of the European campaign when the film was "shot," but regulations have since been made forbidding smoking in aircraft.

The report for 1945 of the British Association of Physical Medicine is signed by the president, Lord Horder. It records useful if not spectacular progress, chiefly in the field of education. Work in this important field comes under two headings. The first is to convince the medical profession as a whole of the value of physical methods in the treatment of a wide range of the morbid conditions arising in a modern civilized community. Under the second heading comes the task of seeing that there is stimulated the growth within the medical profession of a body of practitioners having a special knowledge of the application of physical medicine. The institution by the Royal Colleges last year of a Diploma in Physical Medicine was a good and progressive step towards this end. The Examination Board of the Royal Colleges, as a result of the opinions expressed by the representatives of the B.A.P.M., has now agreed that up to Dec. 31, 1945, candidates for the Diploma in Physical Medicine who produce evidence that they have been, for not less than five years, in charge of the physiotherapy department of a recognized undergraduate teaching hospital or of a recognized hospital, may, at the discretion of the Colleges, be exempted from Part 1 of the examination for the diploma. The three standing committees of the Council (scientific and technical, education and training, policy and public relations) have materially assisted by their investigations into a number of problems, and making recommendations thereon. The committees have considered the promotion of research work on physical medicine apparatus, relations with other scientific organizations, and the inclusion of physical medicine training in plans for postgraduate medical education.

Reports of Societies

INFECTIOUS DISEASES IN CHILDREN

The Fever Group of the Society of Medical Officers of Health arranged a postgraduate day for some eighty maternity and child welfare officers at the North-Eastern (L.C.C.) Fever Hospital on June 30. In the morning Dr. E. H. R. HARRIES and the senior medical staff demonstrated the hospital buildings, contrasting the old type of open ward and the subdivided isolation units of the new wards. Other departments visited were the reception unit for typhus fever patients, the operating theatre and *x*-ray block, a receiving block with six separate reception rooms at the periphery for the different infectious diseases, and a central duty room. Dr. Harries said he always thought that modern fever hospitals with adequate structure, equipment, and staff could become complete children's hospitals, such ward blocks as were necessary being reserved for the treatment of infectious diseases. During the morning also, there was a laboratory demonstration, by Dr. R. CRUICKSHANK and a technical staff, of: (1) modern methods and selective culture media for the bacteriological diagnosis of intestinal infections, whooping-cough, and tuberculosis in childhood; (2) tests for measuring the penicillin and sulphonamide sensitivity of bacteria and for estimating the penicillin content of blood and urine of patients under treatment. Mrs. H. M. R. TOMLINSON showed the Warburg apparatus for estimating bacterial metabolism, and discussed the relation of toxic amines in the gut to the aetiology of infantile, particularly neonatal, diarrhoea.

Prophylaxis of Whooping-cough

In the afternoon Dr. R. CRUICKSHANK opened a discussion on whooping-cough. He said the best lines of attack on this major killing infection of childhood were: (*a*) improved diagnosis in the early stage, and (*b*) protection of susceptible children. Demonstration of lymphocytosis was an inferential diagnostic method applicable early in the disease, but absolute proof could be obtained only by recovering the organism. The "cough-plate" method of doing so had limitations, particularly in private practice and at clinics. The post-nasal swab was more easily taken and handled and gave comparable positive results. Penicillin was necessary in the culture medium to cut down the growth of other organisms. Release swabs for determining freedom from infection were not generally advisable, but could be used in selected cases, as when a child was returning to a highly susceptible community—e.g., a nursery school.

With regard to protection of susceptible children, it had been demonstrated by field trial that mass vaccination was a practical possibility. Standardization of whooping-cough antigens was needed, but there were technical difficulties, though antibody production could be used as a method of assay. Alum-precipitated vaccines probably gave the best results. No antigen afforded complete protection, but the attacks of whooping-cough in vaccinated children were usually mild. A high total dosage was required (100,000 million organisms), and best results were obtained by giving three injections at intervals of not less than three weeks. He had used pertussis antiserum (rabbit) with encouraging results to protect children exposed to whooping-cough in a nursery outbreak. Passive immunization of this type was preferable to vaccination of definite contacts, and he thought that pertussis antiserum might also be tried in the treatment of early cases of whooping-cough. Combined inoculations against whooping-cough and diphtheria were permissible, but diphtheria toxoid should not be mixed with *phenolized* pertussis vaccines, as the phenol damaged toxoid. However, the two antigens were not mutually inhibitory. He agreed that a boosting dose would have great value if given one to two years after primary vaccination.

Dr. N. D. BEGG thought the time would soon come to contemplate one campaign advocating combined protection of all children against whooping-cough and diphtheria at the age of 3 months. Whooping-cough vaccination could clearly not be deferred until the child was older without risking many lives, and there were disturbing indications that the child under 1 year was less safe from diphtheria than had been thought. Dr. E. H. R. HARRIES also considered that the shift in incidence of diphtheria had occurred not only to the older age groups but towards the first year of life. While agreeing on the need for early immunization, he said we must face the fact that young children were more difficult to immunize than older ones and that higher dosage, or more potent antigens, would be required.

Dysentery and Enteritis in Children

Dr. ROBERT SWYER, opening a discussion on the control of dysentery and enteritis in nurseries, said that the prevalent Sonne type of dysentery was often so mild as to escape notice, which was doubtless a cause of its widespread occurrence. Such complications as arose were usually in the upper respiratory tract, and included rhinitis, bronchitis, and otitis media. One child of 9 months had developed keratitis with a small ulcer and some iridocyclitis, and Sonne organisms were recovered from both faeces and conjunctival sac. A serious diagnostic error sometimes encountered was to mistake an intussusception for dysentery; the passage of blood and mucus without faecal matter per rectum should arouse suspicion of the graver condition. Bacteriological investigation might have to be repeated, but with the use of desoxycholate-citrate-agar medium positive results could be expected in over 90% of cases of Sonne dysentery. Serum agglutination might be helpful in convalescence, but a negative result did not rule out the diagnosis.

Patients treated symptomatically recovered rapidly as a rule, but a proportion continued to excrete Sonne organisms until the tenth to twelfth week of disease. Sulphapyridine had effected bacteriological clearance in an average of 5 days compared with 21 days in a control group. In a later investigation of the more insoluble sulphonamides, bacteriological clearance was achieved in 1.8 days with sulphabenzamide, 3.28 days with sulphamidobenzamide, and 2.4 days with succinyl-sulphathiazole. Bacteriological relapses occurred following all three preparations, but were much more frequent (34.6%) with succinylsulphathiazole. Dr. Swyer later demonstrated bacteriological relapses after the use of sulphapyridine. Early relapses probably indicated only intermittent excretion, but with later relapses the possibility of reinfection had to be considered.

Precautions against the spread of infection inside ward units had to be stringent. Apart from the usual barrier-nursing procedures, he favoured the use of destructible diapers, which were placed in a brown-paper bag in a closed bin and later burned in the destructor. All other soiled linen was put into antiseptic in a bin and later transferred to a large tank near the laundry. It was desirable also to separate sharply the nursing duties of feeding and changing children. The bacteriological criteria for determining freedom from infection were three consecutive negative stools or rectal swabs taken at two-day intervals. This had proved satisfactory in practice, and he felt that prolonged bacteriological testing was unjustifiable and would lead to great delay with its attendant risks of cross- and re-infection.

Preventing Epidemic Enteritis in Nurseries

Dr. HAMILTON HOGBEN, speaking of the administrative problems of dysentery and enteritis, particularly in wartime nurseries, which in his area accommodated some 730 young children, said that when these nurseries were set up in the early days of the war he had doubted the advisability of herding young children in unsuitable premises with makeshift equipment and staff inexperienced in the handling of healthy youngsters. Another drawback was that in wartime the children had to be cared for at nursersies for too many hours of the day, particularly during the winter months. He was amazed on looking back, however, to find how little justification there had been for his early fears of widespread infection. In his area there had been only six cases of dysentery and no serious outbreak of diarrhoea in all wartime day nurseries, but two residential nurseries in the country had not enjoyed the same freedom from infection. On the particular administrative problem of preventing epidemic enteritis in non-residential nurseries, he emphasized the need for uniform and efficient theoretical as well as practical training of the junior members of the staff. All the teaching of probationers had been centralized in two parallel courses held at the local technical college.

They had a good nucleus of peacetime nurseries and had insisted on prefabricated buildings when the time came to extend. Such premises, however temporary their construction, were at least designed for the purpose and were preferable to any "adapted" private houses or other buildings. Only in specially designed premises could they get class-rooms of a size that would ensure sufficient air space for each child, cross-ventilation, and floors which could be easily cleaned. Special measures for control of enteritis included adequate washing arrangements for the children, with individual towels and plenty of space between each towel and face-cloth; metal receptacles for soiled napkins; and enough chamber-pots to allow time for cleansing them before use by the next child. Ventilation, temperature, and lighting of the children's lavatories were important to maintain dry floors and reasonable comfort so that toilet could be carried out leisurely and thoroughly. The entrance to the kitchen should be as far away as possible from the lavatories, and all staff should wash their hands as a routine before entering the kitchen to prepare meals. Preparation of infants' feeds should be carried out in a special milk room away from the kitchen and by one member of the staff only. A refrigerator was desirable, if not essential, in every nursery. Food should be delivered daily, and the keeping of food left over—such as gravies, minced meat, etc.—should be avoided. It was preferable to do laundry work on the premises for all children, but in any case adequate facilities were required for washing and sterilizing soiled napkins. Close daily contact between parents and a responsible member of the staff was important in revealing diarrhoea at home, etc. Prompt notification of abnormal stools and immediate isolation of a suspect should be followed by adequate bacteriological investigation. Given these conditions, the dangers of enteritis were not such as to make him fear nursery provision in peacetime for children over 2 years of age. But he was convinced for other reasons that infants should be housed in separate premises, where the crèche could be combined with cot accommodation for healthy children requiring special supervision in feeding difficulties.

Dr. A. T. W. POWELL said he had had 100 cases of Sonne dysentery in his day nurseries, including outbreaks in prefabricated premises. He did not favour closure as a means of limiting spread of infection, but thought that all procedures in the w.c. and washing accommodation needed close supervision. The problem of infection would have to be overcome, as we had to contemplate continuing some daytime nurseries.

The Services

The main building of the Royal Victoria Hospital, Netley, which for 18 months has been occupied by the U.S. Army Medical Services, was returned to the British Army medical authorities on July 19. Brig.-Gen. Charles B. Spruit formally handed the hospital back to Lieut.-Gen. Sir Alexander Hood, Director-General, A.M.S., who in reply said: "We of the British Army Medical Services would like our American friends to have a tangible token to remind them of their stay here, and I therefore present to the United States Medical Services the key of the hospital. I hope it will remind them not only of Netley, but also of the fact that our Services, which have so long been mutually supporting one another, are for all time united."

The *London Gazette* has announced the appointment as M.B.E. (Military Division) of Fl. Lieut. FRANK WILSON LAURIE, R.A.F.V.R. The citation reads as follows:

> One night in December, 1944, in bad weather, a Lancaster aircraft crashed and caught fire outside an airfield boundary. Fl. Lieut. LAURIE, the station medical officer, went to the assistance of the injured crew. He arrived when the worst of the flames had subsided but there was some danger from the fire which was still burning. Working under appalling conditions among the wreckage, in rain and deep mud, he rendered first aid. The mud prevented ambulances approaching the crash and thus delayed the removal of the injured. Some of the crew undoubtedly owe their lives to this officer's prompt and skilful attention. After taking the injured to station sick quarters, Fl. Lieut. LAURIE, although very tired, tended them for a further 12 hours. In January, 1945, two Lancaster aircraft, both carrying long delay-action bombs, crashed at dawn within a few minutes of one another. Fl. Lieut. LAURIE assisted the crew from the first wrecked aircraft, which did not catch fire, rendering first aid as necessary and ignoring the potential danger of bombs exploding. He then turned his attention to the second aircraft. This had caught fire on hitting the ground and two explosions of bombs had already occurred. After seeing one survivor into an ambulance he went among the wreckage to search for other survivors. He was fully aware that there was a considerable danger that further bombs might explode while he was so engaged. Fl. Lieut. LAURIE has set a fine example of gallantry and devotion to duty and has done much to maintain the morale of air crews.

CASUALTIES IN THE MEDICAL SERVICES

Correspondence

Penicillin in Bacterial Endocarditis

SIR,—Since the announcement made in these columns on Feb. 17 (p. 232) of the formation of centres to investigate the therapeutic value of penicillin in bacterial endocarditis 81 patients have received one or more courses of treatment. The results indicate that penicillin can exert a remarkable influence on the course of this disease, but it is also clear that certain systems of dosage are not only ineffective but likely to be harmful.

The first series of patients was divided into three groups; all were given a total of 5 million units, but the duration of treatment was varied as shown in Table I.

TABLE I

	1 million Units a Day for 5 Days	0.5 million Units a Day for 10 Days	0.25 million Units a Day for 20 Days
No. of patients	19	15	12
Relapsed or died	95%	66%	33%
Average duration of "follow-up" of patients without relapse	123 days	110 days	83 days

These results show that even massive doses given for a comparatively short period are usually ineffective. Two other methods of treatment were therefore adopted. In one the daily dose varied from 0.1 to 0.5 million units according to the sensitivity of the infecting organism to penicillin, treatment being continued for 28 days; and in the second group all patients were given 0.5 million units a day for from 21 to 28 days. The results were as follows:

TABLE II

	Dose Regulated according to Sensitivity of Organism	0.5 million Units a Day for 21 to 28 Days
No. of patients	27	19
Relapsed or died	37%	26%
Average duration of "follow-up" of patients without relapse	72 days	75 days

These results do not indicate, as might be supposed, that the sensitivity of the infecting organism is of little significance; they only show that in some cases 0.5 million units a day gives better results than a smaller dose. It is hoped that the next series of patients to be investigated will indicate the significance of the sensitivity of the organism and the optimum daily dose.

The purpose of this letter is to encourage practitioners and consultants to refer patients as soon as a diagnosis is established to the centres listed below. Although the transfer of patients to these hospitals may be inconvenient, there are several reasons why it is desirable. Short courses of penicillin usually only result in harmful delay and may also increase the resistance of the organism to penicillin. These centres have become acquainted with the practical difficulties involved in the prolonged administration of penicillin. The results already obtained also show that conclusions drawn from the treatment of small numbers of patients suffering from this uncommon disease may be entirely fallacious: a co-ordinated effort is more likely to establish the effective dose and the value of such adjuvants as heparin.

The centres which have been established and the persons to whom patients should be referred are as follows:

Belfast.—The Secretary, Belfast Penicillin Clinical Trials Committee, Queen's University Institute of Pathology, Grosvenor Road, Belfast.

Birmingham.—Prof. K. D. Wilkinson, Queen Elizabeth Hospital, Edgbaston, Birmingham, 15.

Bristol.—Prof. C. Bruce Perry, Department of Medicine, Canynge Hall, Whatley Road, Bristol, 8.

Cardiff.—Prof. J. B. Duguid, The Welsh National School of Medicine, Cardiff.

Edinburgh.—Dr. A. R. Gilchrist, Royal Infirmary, Edinburgh.

Glasgow.—Prof. J. W. McNee, or Dr. W. R. Snodgrass, Western Infirmary, Glasgow.

Leeds.—Dr. J. R. H. Towers, 42, Park Square, Leeds, 1.
Liverpool.—Prof. Henry Cohen, Department of Medicine, The University, Liverpool, 3.
London.—(*a*) Sir Alexander Fleming, St. Mary's Hospital, London, W.2; (*b*) Resident Medical Officer, Middlesex Hospital, London, W.1.; (*c*) Prof. R. V. Christie, Hill End Hospital (St. Bartholomew's), St. Albans, Herts.
Manchester.—The Resident Medical Officer, Manchester Royal Infirmary, Manchester, 13.
Newcastle.—Prof. F. J. Nattrass, Royal Victoria Infirmary, Newcastle-upon-Tyne.
Sheffield.—Prof. E. J. Wayne, Royal Hospital, Sheffield, 1.

—I am, etc.,

RONALD V. CHRISTIE,
Secretary, Penicillin Clinical Trials Committee.

Masking Syphilis with Penicillin

SIR,—I was very interested in the letter by Brigadier T. E. Osmond (June 16, p. 853) on the effect of penicillin in delaying the appearance of a syphilitic sore. This probable effect had already been pointed out by Major F. L. Lydon, R.A.M.C., and myself in an article in the *Journal* of Jan. 27 last (p. 110). With the increasing use of penicillin in the treatment of gonorrhoea (both fresh and relapsed) more of these cases are coming to light, and our original plea for extended surveillance cannot be too strongly or too frequently emphasized. Major Lydon has recently informed me of one of his own cases with a delayed incubation period, and the following from my own records serves well to illustrate the point.

Pte. A. was admitted to a hospital in the Middle East on Nov. 2, 1944, with an infected irregular painful fraenal sore and associated right inguinal adenitis (clinical soft sore) and purulent urethral discharge showing many intracellular gonococci. The only exposure to infection was on Oct. 20, 1944. The fraenum was torn during coitus and treated with "a lotion and sulphonamide powder." Dark-ground examination of the sore was negative on the three days following admission. From Nov. 4 to Nov. 8, 28 g. of sulphathiazole was given. The sore was treated with eusol dressings. I saw this case on Nov. 14. Urethral smear still showed gonococci. The sore was healed and the adenitis subsided. On Nov. 16 penicillin was administered intramuscularly in doses of 20,000 units three-hourly to a total of 100,000 units. There was a rapid clinical cure of the gonorrhoea. On Dec. 19 the fraenal sore recurred in the same position; and dark-ground examination on the following day was positive to *Sp. pallida.* Blood Kahn was negative. Routine antisyphilitic treatment (arsenic and bismuth) was started on Dec. 20. No Herxheimer effect was noted. Treatment was completed by short-term penicillin therapy one week later. Blood Kahn was negative three months later.

The incubation period, then, was 60 days. Apart from the effect of penicillin in this case, it is important to note, too, that antiseptics were applied early to the original sore, thus encouraging rapid healing. It is reasonable to suppose that had antiseptics not been applied healing might have been delayed, allowing syphilis to be diagnosed before the institution of penicillin therapy (26 days after exposure).

Finally, I have recently noted a few cases of gonorrhoea treated with two or even three courses of 100,000 or 150,000 units of penicillin on account of relapse or fresh infection within a period of six weeks. It would appear, then, in view of what has already been said on the masking of syphilis, that such cases must be even more carefully assessed on completing their six-months period of surveillance.—I am, etc.,

W. R. SCOTT COWE,
Major, R.A.M.C.; Specialist in Venereology.

Saline, Sulphaguanidine, and the Amoeba

SIR,—We view with increasing alarm the frequency with which amoebiasis may remain undiagnosed in cases that have received treatment for presumed bacillary dysentery. In 1942, during the Burma retreat and its aftermath, many cases of "dysentery, clinical" were evacuated to Dinapore. These cases were mostly 10 to 14 days old and had been treated with salines. Repeated examination of the stools often failed to demonstrate amoebae, but routine sigmoidoscopy commonly revealed characteristic ulcers from which amoebae were sometimes recovered; in all cases the ulcers healed rapidly on emetine.

In 1943–4 in Assam it was usual to receive fresh cases, and the diagnosis of amoebiasis was so readily made by careful stool examination that instrumentation was rarely necessary. We are now stationed on Ramree Island. We draw our cases largely from the mainland and the 1942 position has recurred, the only difference being that patients have received sulphaguanidine in place of saline before admission. Once again we find that recourse to sigmoidoscopy has commonly to be made before the diagnosis of amoebiasis is established.

The comparative absence of flies during the monsoon, the high level of the subsoil water, and the consumption of tinned rations are all factors favouring amoebic rather than bacillary dysentery. The fact that symptoms may be controlled by sulphaguanidine treatment is to us a source of anxiety rather than satisfaction; we feel that, before we became aware of this danger, we returned to their units some men who undoubtedly had untreated amoebiasis. We believe that the majority of these cases represent not a double infection of bacillary and amoebic dysentery, but a pure amoebiasis in which the ulcers are secondarily infected with such organisms as the haemolytic streptococcus and Vincent's spirillum (Acton, H. W., and Knowles, R., *The Dysenteries of India,* Thacker Spink, Calcutta, 1928). This secondary infection is eliminated by sulphaguanidine, as is shown by a recent necropsy in which typical amoebic ulcers were perfectly clean, in striking contrast to the usual picture.

As the war moves further east we urge that this danger should be more widely appreciated, and that a serious attempt should be made wherever possible to recover amoebae from the stools before instituting empirical sulphaguanidine treatment. Where sulphaguanidine has perforce to be used, it must be realized that the apparent control of symptoms by no means excludes the presence of amoebiasis.—We are, etc.,

Excision of Patella

SIR,—The letter from Mr. H. A. T. Fairbank on excision of the patella (July 14, p. 62) is most timely, and many will agree with his warning concerning the readiness with which some surgeons take the easy way of removing the patella without giving a fair trial to more conservative methods. I am among those who consider that the theory that this bone can be removed with impunity and plays no indispensable part in the functioning of the knee-joint has been accepted too readily. Without long-term statistical evidence, that is so necessary and yet lacking, the wisdom of such a drastic step as removal cannot be definitely established.

If the human patella serves no useful purpose, common sense, quite apart from morphological argument, surely indicates that such a large and well-defined structure would have disappeared or would have been represented by some mere vestigial element millions of years ago. The patella is often dismissed in airy fashion as a mere sesamoid bone, but even the humblest sesamoid has a function to perform; hence its persistence through the ages. Could any structure look less like a useless vestigial remnant than the human patella, and can there be any doubt that it plays an important part in the complicated mechanism of the knee-joint?

In the experimental work that preceded my Hunterian lectures at the Royal College of Surgeons of England on osteoarthritis and loose bodies in joints, I was able to show that lack of cartilaginous apposition between the patella and trochlear surface of the femur actually caused disappearance of the articular cartilage over the trochlear surface. I append short notes of two experiments:

Expt. 13.—The knee of a rabbit was fully flexed and immobilized by staples driven on either side into the lower end of the femur and the upper end of the tibia, the joint being unopened. The animal was killed 6 weeks later and it was found that the articular cartilage had disappeared from the trochlear surface of the femur. Owing to full flexion of the joint, its cartilaginous surface had not been in contact with the cartilaginous surface of the patella.

Expt. 11.—The patella of a rabbit was completely dislocated to the outer side of the joint. After death 10 weeks later, the articular cartilage of the trochlear surface of the femur had almost completely disappeared, evidently through lack of cartilaginous apposition. The articular cartilage elsewhere was normal, and on the outer side of the femoral condyle, where the patella had articulated, a new articular surface had developed consisting of smooth connective tissue undergoing, in places, cartilaginous transformation.

These experiments were performed more than 20 years ago and duly published. They have evidently escaped Mr. Fairbank's notice, although he mentions recent experimental work on somewhat similar lines by Bruce and Walmsley (1942) and Colin (1944) and published in America. There is an obvious fallacy in applying experiments on animals to human beings, but the findings are certainly suggestive.

Redfern, many years ago, found also that the articular cartilage underwent degenerative changes after experimental amputations through joints. Specimens formerly in the R.C.S. Museum ((pre-war Nos. 440.1 and 442.2: I have been unable to check if these survived the holocaust due to enemy action) show the lower ends of the femora from cases of amputation through the knee-joint. In both cases, the articular cartilage is very thin and has in places degenerated. One sees examples of the same kind in old unreduced dislocations, both congenital and acquired, and in various deformities. All these facts show that when normal cartilaginous apposition ceases, degeneration of the articular cartilage occurs which is indistinguishable from that seen in the early stages of osteo-arthritis, and may be followed by the complete picture.

After these animadversions concerning removal of the patella, I hasten to observe that the operation is, in my experience, occasionally of value. In addition to the badly comminuted fracture of the patella, where the normal smooth articular surface cannot be reconstituted, it is occasionally of value in cases of osteo-arthritis of the knee, where the disease is concentrated in the patello-trochlear area and where pain due to friction is intolerable. It is an alternative to arthrodesis or excision which may preserve a useful range of movement. I have been pleased also with the results of excision of the patella in long-standing cases of recurrent dislocation, when painful and frequent attacks of dislocation occur in spite of previous plastic operations, and which are uncontrollable by an instrument.

It is worthy of observation that the aesthetic effect of excision of the patella is far from satisfactory: in fact, the knee looks like "nothing on earth," particularly on flexion. This is a point of no small importance to the young of both sexes and even to the not so young.—I am, etc.,

London, W.1. A. G. TIMBRELL FISHER.

March Fracture

SIR,—Stamping is still going on in the Army in spite of any order in the Drill Book. Drill sergeants are teaching recruits to stamp at their "turns," and men are being invalided in consequence of the injury it causes to their feet. I wonder whether Dr. Ian D. Kitchin's patients (July 14, p. 64) have been subjected to this ugly, ridiculous ritual. What are the medical officers doing about it?—I am, etc.,

Stanmore. G. LENTHAL CHEATLE.

Effort Syndrome in West African Soldiers

SIR,—I was interested in Major Goddard's article on effort syndrome in the West African soldier (June 30, p. 908), and without disputing his conclusion that "the influence of European civilization is an important factor in determining the incidence of effort syndrome in the West African," I do not agree that the facts recorded in his article lend any colour to this belief. It is clear from the article that the hospital where the cases were recorded did not serve even approximately a representative sample of Gold Coast soldiers of the R.W.A.F.F. The proportions of Christians in his 12 cases and in the 40 cases in the surgical ward are 100% and 50% respectively. These proportions would be strong evidence that effort syndrome occurs among Christians relatively more frequently than diseases requiring surgical treatment, if there were not reason to believe that the two groups are differently selected.

I have no figures readily available, but it may be taken that Northern Territory, Ashanti, and Colony soldiers will, relatively to each other, consist preponderantly of Mohammedans, pagans, and Christians. Without knowing the actual proportions of Christians and non-Christians, it is possible also to conclude by similar arguments from the figures quoted of the relative numbers enlisted in the three parts that Christians are more liable to disease requiring surgical treatment. The true answer is, of course, that Major Goddard's cases were taken from what is anything but a random sample, and conclusions drawn from study of the relative frequencies are useless.

I suggest that what has happened is this. The hospital in question was probably at Accra, Kumasi, or perhaps Takoradi (Accra and Kumasi are marked on his map; Takoradi is on the coast roughly south of Kumasi). These three stations have adequate communications. For the period in question the Gold Coast was surrounded by Vichy French territories, and most units with primarily combatant duties were presumably in distant stations like Tamale (also marked on his map). Such units would be predominantly pagan and Mohammedan. Even if the M.O. suspected a psychiatric disorder, the soldier would be much less likely to be sent on the long journey down to the south. The argument is supported by the fact that, though 53% of serving soldiers came from the N.T., 5 out of every 40 patients in the surgical ward were Mohammedans. Very likely, however, effort syndrome would not even be diagnosed. Speaking from experience as an infantry officer in the R.W.A.F.F., I can say that if one encouraged every man who complained that "my chest do humbug me" to go sick, one would seldom have a reasonable parade strength at all. Suppose, however, that effort syndrome cases reach a sympathetic R.M.O., he then has the same difficulty as Major Goddard, who "found the language difficulty a great hindrance in getting *en rapport* with these cases," and failure to diagnose the condition is more than possible. The argument is equally valid when applied to the Christian and non-Christan elements among the units near to the hospital.

The article shows exactly what one might expect: that effort syndrome cases reach a base hospital more easily when the sufferer is educated. What figures of this sort can never show is whether the disease is more frequent among educated than among uneducated Africans.—I am, etc.,

M. D. W. ELPHINSTONE,
Major, late R.W.A.F.F.

Re-employment of the Consumptive

SIR,—Those of us who, as tuberculosis officers, have to advise the consumptive about his employment, and who frequently have to issue certificates to help the patient to obtain work, are well aware of the difficulties with which he is faced and the anxiety that these difficulties cause. It is therefore most gratifying that the patient disabled by tuberculosis comes within the scope of the new Disablement and Rehabilitation Act.

There are, however, certain aspects of tuberculosis in regard to employment which are not widely enough recognized. First, the fresh-air fallacy should be exposed. It is extraordinary how widespread is the belief that fresh air is essential to the consumptive. No doubt this misconception is fostered by the simple observation that in sanatoria the gospel of fresh air is correctly and extensively both preached and practised. But in many cases both patient and public mistake this hygienic measure for a valuable therapeutic device, and so it is not uncommon to find that a patient seeks outdoor work, and perhaps thinks of throwing up a useful sedentary occupation, not realizing that it is the latter rather than the former which offers him the better opportunity to keep up that all-important measure—the regular rest-hour. Furthermore, the exposure to inclement weather and getting wet through may have unpleasant consequences if his home is not so well equipped for drying clothes as was his sanatorium.

I would suggest that a second fallacy is the dread of infection. At the present time the aetiology of consumption is not properly understood. Why is it that some persons become consumptives while others overcome a primary infection and thereafter experience no further trouble? There are advocates of the theory of "endogenous exacerbation," and there are advocates of the theory of "exogenous reinfection," but there is no agreement among the experts that the consumptive with a positive sputum can transmit the disease of consumption as distinct from transmitting tuberculosis. Surely, then, if there is no proof of this fact, but rather considerable debate about it, the public should not be encouraged to take the view that the sputum-positive patient is a menace to the health of his contacts at work. Especially is this the case if the patient has been to a sanatorium and has learnt the principles of hygiene there taught.

The type of work for which a consumptive is suitable depends on many factors, but these two especially: first, the nature of his previous job, and, secondly, whether his disease is quiescent or whether he is a "good chronic." At the one extreme, the man with a sedentary occupation and good hours and with quiescent disease should be encouraged and assisted to remain in his previous employment, and obstacles to this end overcome. At the other extreme, the man with active disease and a previously strenuous job is *par excellence* the patient requiring rehabilitation. It is grossly unfair to an individual that because of a positive sputum he should be debarred from earning a living if he so desires. It seems to me that for such cases rehabilitation should often be directed toward those crafts which the patient may have had the opportunity to learn by way of diversional therapy in a sanatorium, especially leather work, toy-making, fine embroidery, draughtsmanship, etc.

To the consumptive re-employment in society is a most vital problem. When the Disabled Persons (Employment) Act is functioning more extensively we must see to it that suitable jobs are kept for the tuberculous, whose problem is different from a surgical disablement, and a positive sputum must not become a sentence of permanent unemployment or ostracism to an outdoor, inclement, livelihood.—I am, etc.,

Reading. W. H. TATTERSALL.

Day Nurseries

SIR,—As circumstances prevented me from supporting the Archbishop of Westminster's criticisms at the present conference on maternity and child welfare may I ask the hospitality of your columns to do so?

Day nurseries mean that mothers with young children are going out to work for a living. What are the effects of this practice on the individuals most concerned?

1. *The Father.*—Father is generally forgotten or ignored in discussing this problem, but he is not unimportant. Part of his job (of bread-winning) is taken from him, and part of his own proper responsibility is also taken from him. In my experience he tends, lacking the stimulus of this responsibility, to relapse into illness or unemployment, or at best to stay content in the poor job with inadequate pay (and, incidentally, to encourage the bad employer to maintain low rates of wages). Moreover, a decent man does not like to see his wife doing what he knows he ought to be managing single-handed, and the consequent irritation, coupled with disgruntlement at having to get some of his own meals, does not tend to improve the family atmosphere.

2. *The Mother.*—One of the commonest problems in industrial general practice is the woman who comes in with a panel card and a wedding ring. She is not doing one job: she is doing two. She gets up early, does as much as she can in the house, rushes off to the day nursery, and then on to work. After she has done her "day's work" she comes back (via the day nursery) and starts again on her household duties. No wonder she is tired and irritable, and harassed by the threatening alternatives—"more money but more work," or "less work but less money." Moreover, such a woman cannot obviously have any more children if she is to remain at work. In these days of dangerously low birth rates is this an aspect of the problem which we can afford to neglect?

3. *The Child.*—What the young child needs above all else is mother's love and protection. But what does he feel? What would he say if he could express himself? "Mummy does not love me as she used to; she goes away all day and leaves me with those people in the nursery." And then, deprived of her society all day, what does he feel when he is taken home in the evening and finds her cross and irritable and too busy with the housework to have time to spare for him?

Sir, the day nursery may be one of the inevitable necessities of total war, but in peace every one of them is a blot on our civilization.—I am, etc.,

Wandsworth. F. GRAY.

Hydatid Disease of the Lung

SIR,—In the *Journal* of March 17 (p. 375) there appears an annotation, under the heading "Cave Canem," on a paper by Barrett and Thomas dealing with hydatid disease of the lung. Many of the points enumerated are not in accordance with my experience of hydatid extending over nearly forty years. Erosion of the ribs does not occur, but in large hydatids there is an associated bulging of the chest wall. Multiple hydatids of the lung are rare. The outline of hydatid is always sharply cut unless there has been a leakage or unless there is an associated pneumonitis or pleurisy. The crescent of air is only seen in leaking hydatid. I doubt whether hydatids disappear spontaneously; if they disappear it is because of rupture into a bronchus.

In regard to operation, the one of choice is "marsupialization"—i.e., the cyst is turned out, and if the hydatid is a large one it may be necessary to insert a drainage tube; otherwise the wound is closed.—I am, etc.,

Sydney. J. G. EDWARDS.

Human Creeping Myiasis

SIR,—I have read with interest the very full account by Dr. R. G. Turner (July 7, p. 11) of a case of human creeping myiasis, and would like to record an experience of mine three years ago.

A local doctor reported to me the case of a boy aged 16, who had been complaining of pains in the shoulders and in the muscles of the upper arms and in the intercostal muscles. He stated that a lump came on the left shoulder which he squeezed, and expressed "matter." The boy was a farmer's son from a remote mountainous area where bacon is a staple food, and the pigs eaten are often upwards of 2 years old and for a large portion of their lives are not sty-fed but run loose. In the circumstances trichinosis was suspected. This had not been uncommon in the district many years ago, though it has disappeared for about a generation. Together with Mr. J. O'Brien, veterinary surgeon, I investigated the matter. Practically all of the pig in question had been eaten and *Trichinella spiralis* could not be found in the small portion remaining. The boy was in good health but complained of wandering pains in the shoulders, chest, and arms. His temperature was normal and physical examination was negative. The boy and the premises were kept under observation, and a little later he reported to us with another swelling. This was on the left upper arm. It was small, red, and slightly tender, and was obviously about to discharge. On squeezing, a white maggot was expressed. This was immediately recognized by Mr. O'Brien as the larva of the warble-fly. About two weeks later a further larva was expressed, this time over the right scapula. This was the last of the larvae. During all this period the boy did not complain of illness other than the pains referred to.

—I am, etc.,

Castlebar, Co. Mayo. D. F. MCCARTHY.

The Training of the General Practitioner

SIR,—I endorse most of Dr. E. K. Mackenzie's remarks (*Journal*, June 9, p. 823) on obstetric specialism, but do not his observations apply with equal cogency to every specialism in medicine—namely, the need for wider experience and greater sense of perspective on the part of the young graduate before he is permitted to specialize? While a diploma may not be superfluous to the possessor of the M.R.C.P. or the F.R.C.S., surely it is no substitute for either. I need not stress the point further.

There is need, however, for a new diploma—one in general practice, a D.G.P. Whether the medical services of this country are to be administered by the profession or by the State, the standard of medical practice will depend on the competence of the general practitioner more than on anyone else. If with our teaching schools first things come first, their principal aim should be to turn out qualified competent practitioners; but the medical schools are turning out embryo specialists, of whom a few indeed become specialists while the majority become general practitioners.

It can scarcely be pretended that the young graduate has received the right kind of training for general practice, although by law he is permitted to engage in independent practice as soon as he has registered his qualification. To obviate this a diploma, after a searching examination not earlier than the end of the third year following graduation, would appear to be highly desirable. General practice, where it is efficient and sufficient, is of vastly greater value to the public than any specialism. Where the standard of practice is low the public suffers to an incalculable degree. To ensure the high standard that the public deserves and needs general practice should be regarded as the most important specialty in medicine, and the future G.P. should possess a diploma guaranteeing proficiency before he is permitted to embark on independent practice.

For the first two years after graduation the training of the young doctor, whether he aims at being a consultant, specialist, or G.P., should be on parallel lines—hospital appointments. Thereafter the aspirant to general practice should go as an assistant into general practice, and he should be permitted to take the diploma not earlier than the end of the third year after graduation. As soon as he finds it expedient (afterwards) he could embark on independent practice or become a partner. The examination should be on the lines of the M.R.C.P., the special section of which would be replaced by a section on general practice, including social aspects of medicine and citizenship.

There is no walk of life that gives more scope for personality and individuality than general practice, but until its prestige is sufficiently enhanced to attract some of the best brains (and it affords scope for the very best) the man in the street is not going to enjoy a better medical service. It is generally admitted that much of the training of the undergraduate would be better done by a teacher with a "general practice" outlook than by the pure specialist. With correct background of training an interchange of personnel between general practice and the teaching centres would come about naturally and smoothly to the advantage of both. With adequate hospital accommodation for the sick there should be enough house appointments for the proper training of G.P.s, specialists, and consultants.—I am, etc.,

Fraserburgh. J. Macleod.

*** A diploma in general practice was suggested by Dr. Frank Gray in an article on the general practitioner of the future, published in the *Supplement* of May 27, 1944, p. 121.—Ed., *B.M.J.*

Weight Reduction by Dieting

Sir,—The following observations conducted on myself may be of interest. I have often been asked by patients to put them on a reducing diet, and have consequently compiled a detailed regimen, of adequate calorie value, but largely excluding those substances with a high carbohydrate content. Provided there was strict observance by the patient of the rules laid down, the results were eminently satisfactory, a steady loss of 1 to 2 lb. a week being maintained over a long period.

Recently certain causes prompted me to consider adopting my own regimen for myself. They were: shortage of clothing coupons, excessive strain on various supporting buttons, notably of the trousers, and a hopeless prospect of ever insinuating my person into my pre-war civilian clothes. I accordingly started dieting, but being of an impatient nature I exercised a more strict control, and hence lost weight at an increased pace. The diet as laid down included one fast day a week; and on this day, as I felt so very well and suffered no ill effects, I decided to extend it, which I have done indefinitely, with what seem to me to be quite remarkable results.

For the last 28 days I have been fasting—details of which are as follows and strictly accurate:

(i) I have eaten no food of any sort whatsoever.
(ii) I have taken copious non-alcoholic fluids (some sweetened).
(iii) I have maintained an adequate daily vitamin dosage of A, B_1, B_2, C, and D (in tablet form).
(iv) I have taken no alcohol.
(v) I have taken an alkali mixture three times a day.

On the above-mentioned diet I have maintained very full and busy working days, including office work, long drives in a car, aeroplane trips, and in the light evenings plenty of exercise, including several sets of tennis, long walks, etc. During this period of 28 days I have lost 30 lb. in weight, felt extremely fit, slept well, had no headaches, lassitude, or feeling of weakness—and in fact never felt better in my life. My bowels have not been opened for the last 15 days. The mental strain on occasions was admittedly considerable, but my eye is bright, my skin clear, and my brain functions normally. Furthermore, as my clothes are now very comfortable, and I can see my genitalia from the upright position, I consider the experiment to be successfully concluded.

I was always taught as a student that there were several prerequisites of safe dieting, which included complete rest in bed, slow reduction over a long period, no complete starvation. While I would not consider putting a patient on so rigid a diet, I should be most interested to hear the views of others in this matter. Doubtless I shall be derided and criticized, but I shall at least have the satisfaction of being able to put my clothes on direct from the moth balls. For sartorial and gastronomic reasons I refrain from publication of my name and sign myself

"Apollonian."

Alien Doctors

Sir,—I was delighted to see Capt. J. Joseph's letter (July 14, p. 66), though somewhat guilty that I had not written earlier myself to challenge the recent evidences of a familiar reaction.

Of course, among the refugee doctors there are some unethical black sheep, but these are not unknown in our own British professional group. Since 1933 I have come across most of the refugees in my own field of medicine, and I have a high opinion of their skill, integrity, and professional spirit. In the early days of the war I was "plagued" by their anxiety to work in the national services. The Army had limitations on their employment; the E.M.S. found it difficult to use them, and, frustrated as our warm allies in this war, they had to turn to other forms of valuable work for the health of the country. An increasing number have recently been at work in the Services, where they have made a distinguished contribution.

The opinion has been expressed that the new health services should not be operated until there are enough doctors to make it possible. In psychiatry, at any rate, our shortage of well-trained men will be great, and, in my opinion, we urgently need the continued help of such refugee specialists as can be retained in this country.

Innuendo and undocumented criticism are poor weapons for a scientific profession. The B.M.A. would do an invaluable service by appointing a small impartial committee to receive and sift whatever evidence is available on this topic from all sources, so that advice on future policy may be given to the Home Office.—I am, etc.,

London, W.1. J. R. Rees.

Sir,—The letter of Majors L. T. Clarke and R. S. MacHardy (July 7, p. 30) cannot remain unanswered by refugee doctors. It is a misleading overstatement to speak of an inundation of the fields of British medical practice by alien doctors. So far as I know, there are 40-odd Austrian and 50-odd Czechoslovak "quota doctors" who have obtained British qualifications, are on the permanent *Medical Register,* and were granted the privilege of establishing themselves in medical practice. Apart from these there are roughly 300 doctors from Austria, Czechoslovakia, and Germany who, although mainly highly skilled medical men of middle age, are mostly engaged in assistantships and hospital work in junior capacities—and with junior salaries—and who are only on the temporary *Register* in order to comply with the law. A trifling handful of about 5 or 6 have obtained British qualifications and are duly registered but are not included in the quota. Inundation, indeed!

The alien doctors know, and are sorry for, the sacrifices of their British colleagues caused by their absence from their practices for nearly six years, but I think it would not be unfair to mention that so many practices have been saved and maintained by the efforts of assistants and locumtenents. Our sacrifice of pride and dignity which we suffered when we had to leave our former homelands is insignificant compared with the sacrifice of life and health by those who failed to get a sanctuary in this country. Do your correspondents know how few of us succeeded in joining the Allied Forces, and how many have applied in vain for appointments with U.N.R.R.A. and the Military Government? Certainly many refugee doctors would be glad to replace British doctors in liberated Europe, having been entrusted with the health and life of British people for so many years. But as to the privilege of "practising among one's own folk," I know at least two alien doctors who have tasted life in concentration camps and abhor the idea of practising among people who are their own folk no longer.—I am, etc.,

Penarth. MARCELL GANG.

⁂ This correspondence is now closed.—ED., *B.M.J.*

Newspaper Publicity

SIR,—A paper by me entitled "Return of Virility after Prefrontal Leucotomy" appeared in the *Lancet* on Sept. 9, 1944. The sole reason for publication was to draw attention to an unusual physical result of prefrontal leucotomy and discuss possible physiological implications. This paper has evidently been the subject of an article which appeared in the *Sunday Dispatch*, July 15, 1945, entitled "The Story of a Scientific Miracle. A Man had Worry Removed from his Brain." The article was so written that one would be justified in inferring that it was the result of a personal interview given by me. It is stated that I was one of the first two doctors in this country to put prefrontal leucotomy into practice. In point of fact I can claim no credit at all in its introduction into this country. Coupled with my name are those of the late Mr. Wilfred Willway and Dr. Max Reiss. There is also a quotation from the article which is textually incorrect, and reads as if it were a verbatim statement of mine. The newspaper article has been published without any reference to the source of the material, nor is there anything to suggest that it is based on a *Lancet* publication.

I desire to state that the newspaper article has been published without my knowledge or consent. The *Sunday Dispatch* is a paper that I see only occasionally, and I have never heard before of the author of the article, who signs himself Edward H. Spire.—I am, etc.,

Bristol Mental Hospital. R. E. HEMPHILL, M.D., D.P.M.

Medico-Legal

THE YOUNG OFFENDER

The committee of two which inquired into the provision and administration of remand homes by the London County Council touched on a problem far wider than the scope of its actual reference.[1] Mr. G. Russell Vick, K.C., and Miss Myra Curtis were appointed to clear up the controversy which was started when Mr. John Watson, chairman of the Tower Bridge Juvenile Court, and Mr. Henriques, chairman of the Toynbee Hall Juvenile Court, published severe criticisms of the council's conduct of remand homes for girls. The commissioners found that in the particular case of a child of seven which had focused attention on the home, Mr. Watson's statement that she was wrongly treated was inexact and misleading; that the child was properly received into the home at Marlesford Lodge and properly cared for while there. On the other hand, there was evidence of overcrowding in the council's remand homes in the past, partly due to war conditions. Marlesford Lodge, they found, needed further adaptation and improvement and its administration had lacked interest and enterprise. It was very much understaffed and needed, in the commissioner's opinion, better qualified and better paid workers. They found that thirty or forty girls passed their recreation time sitting in one room with nothing whatever to do, listless and conscious of frittering away their time. At Stamford House, a boys' remand home, the boys were by contrast actively and contentedly employed at all kinds of handwork. The committee thought that the L.C.C.'s resources are adequate to provide books and materials for needlework and handicraft, and also to avoid the shortage of clothing of which complaint was made.

The chief criticisms of the magistrates were, however, directed against what they thought to be faulty segregation of what may be called sexually delinquent from sexually innocent children. The statutory rules governing remand homes lay down only that care shall be taken to keep in separation any boy or girl who may be likely to exercise a bad influence over others. Mr. Watson strongly held the view that "innocent" girls should be kept out of the remand homes altogether and that girls sent there should be classified into two groups: those sent for misbehaviour and for sexual misbehaviour respectively. Committed girls should, he held, be kept apart from remanded girls, and the sexually immoral separated from the sexually moral. Mr. Henriques wished to divide girls over fourteen into three groups, to be kept entirely separate: ordinary delinquents, moral delinquents, and those awaiting a school. On the other hand, the Home Office view is that local authorities should apply the separation rule as each thinks best and that classification according to sexual experience is undesirable even if it is practicable. The commissioners thought the magistrates were wrong in charging the L.C.C. with grave dereliction of duty because it had not achieved a standard of segregation which had not been authoritatively laid down or even generally agreed. They did not regard the Marlesford Lodge arrangements as the scandal which the Press treatment of the controversy had suggested they were. On the other hand, they found that the L.C.C. had not worked out a definite segregation policy and would be well advised to do so. The committee's own view was that certain classes of children should be either removed from the remand home or housed in a separate part of it—viz., children under eight, girls suffering from venereal disease (who are already separated), children and young persons committed to approved schools, and those under punitive detention. They would house boys and girls over eight in separate homes, and keep the age group 8–12 apart from other children for most purposes. The remainder, they thought, need not be classified on any definite formula, but the superintendent, assisted by skilled supervisors, ought to have facilities for separating them. They also recommended that children should be fully occupied, that the Home Office in consultation with local authorities should review the pay, recruitment, and training of staffs, and that machinery should be established by the Home Office for easy and frequent consultation between the Home Office, the L.C.C., magistrates, probation officers, and superintendents.

The learned correspondent who dealt with the problem in a long article in the *Times* of March 15 doubted, however, whether such machinery would secure adequate co-ordination. Throughout the whole penal system, except for probation, judges and magistrates have no share in the management of corrective institutions. He thinks that a choice may have to be made between handing over remand homes and kindred institutions to a committee of magistrates, and setting up a special authority with the duty of prescribing and supervising treatment of defined classes of persons, particularly young persons, whom the courts would otherwise sentence to prison or Borstal. Before instituting such drastic reforms, the co-ordination of the judicial and executive authorities ought doubtless to be given a fair trial. What, however, seems to be most needed is a far more general sense that the problem of dealing creatively with young delinquents is really urgent and important, and that these children are not merely a nuisance but the raw material of our future as a nation.

---

[1] H.M. Stationery Office, 1945. Cmd. 6594. (6d.)

With the 86th report of the Royal Eastern Counties' Institution for the Mentally Defective at Colchester is enclosed a printed tribute to Dr. F. Douglas Turner, C.B.E. Near the end of last year Dr. Turner approached the board saying that with advancing years he found that the burden of running this vast institution was getting beyond his powers and he felt he must retire. As he had wished to do so before the war but was persuaded to stay on, the request could not be refused, and Dr. Turner retired at the end of February, 1945, to be succeeded by Dr. E. Randal Hull. "To many of us Dr. Turner had been the R.E.C.I., and we cannot think of it without his wise, all-pervading, kindly influence. He came to the Institution in 1905 as medical officer, having started in general practice at Huddersfield, which he gave up after five years owing to eye trouble. On the death of his father, Mr. J. J. C. Turner, in 1914, he succeeded him as medical superintendent. At that time the number of beds in the Institution was 250; to-day the number of beds is 2,150. It has been under his direct supervision that this enormous expansion has occurred." The eulogy from which this brief passage is quoted has an accompanying portrait.

Obituary

SIR W. GIRLING BALL, F.R.C.S.

Surgeon to St. Bartholomew's Hospital

It had been known to his friends for some months that Sir Girling Ball's health was failing; he had had to give up the chairmanship of the Services Committee of the Central Medical War Committee, though remaining, at least nominally, a member. But he was not far advanced in the sixties, and until his breakdown he conveyed such an impression of robustness, both of mind and body, that many more years might have been predicted for him. His death on July 16 is a great loss to the branch of surgery he had made his own and to medical education.

With St. Bartholomew's Hospital, and the place it occupied in the City of London, William Girling Ball's whole career was bound up. He was not by birth a Londoner, but the home of his childhood was only ten miles away, at Barnet, in Hertfordshire, and it was to the City he went to school. As a boy of 13 he entered Merchant Taylors', then located just by the City wall, west of Aldersgate, and it was an extraordinary happiness to him, forty years later, owing to the removal of the school out into Middlesex, to be able to acquire for St. Bartholomew's Hospital College the almost sacred ground on which Merchant Taylors' had stood from the time when Charterhouse School left for Godalming.

Girling Ball remained at Merchant Taylors' until 1900, when he entered St. Bartholomew's, qualifying in 1905. He served as house-surgeon under Sir Anthony Bowlby. For four years, from 1907 to 1911, he was demonstrator of pathology at Bart's, and from 1911 to 1913 clinical assistant at St. Peter's Hospital for Stone. It may have been there that his interest was directed to urology. He was a general surgeon, but his special interest lay in genito-urinary work.

His appointment to the senior staff at Bart's was made in 1913, and he became residential warden of the College, a post long held in former years by the famous historian of the hospital, Sir Norman Moore. Ball retained this post until 1921; he was also sub-dean from 1920 to 1925. In 1930 he succeeded Dr. T. W. Shore as dean of the college. Dr. Shore had reigned in that position for twenty-four years. It was said of Augustus Caesar that he had found a city of brick and had left it a city of marble. Shore and Ball between them did a similar work for St. Bartholomew's. Forty years ago it had the reputation of being the dingiest and shabbiest of the London medical schools, though no exterior drab could dim the brilliance of the work that was done there nor the greatness of Bart's men. In Shore's time as dean great improvements were made, the library completed, a new dissecting room built, and modern operating theatres and pathological laboratories and a surgical block. Ball crowned his predecessor's work, and the consummation was reached in 1935, when, on the departure of Merchant Taylors' School, the pre-clinical departments were housed on the site in buildings opened by the Prince of Wales, afterwards Edward VIII. Here on a tranquil island, still within the confines of the City, only a few minutes' walk from the main hospital, was to be found an extraordinary blend of the mediaeval and the modern. Ball himself rejoiced especially in the college hall, with its hammer-beam roof, now sadly damaged by enemy bombs, and in the mellowed red brick of the Charterhouse buildings close by; but the equipment of the College in its new home was as up-to-date as any medical school could wish. Later the new department of anatomy was opened—as fine a department as can be found anywhere. Much of this was due to the drive and foresight of Girling Ball and the donations he was able to coax out of City and other purses. During that period, from 1936 to 1940, he was dean of the Faculty of Medicine of the University of London and member of the Senate.

During the first European war Girling Ball was medical officer in charge of the military wing at Bart's, and also, in 1917-18, surgeon specialist attached to the 53rd General Hospital (T.F.) of the British Expeditionary Force. When the second European war was threatening and the evacuation of London medical schools became necessary, it was a great satisfaction to him to have got the pre-clinical departments in working order at Cambridge by September, 1939, and part of the clinical school established at Hill End, St. Albans. He was made sector head of St. Bartholomew's and Royal Free Hospitals under the E.M.S. in March, 1939. He had also become, in September, 1938, surgical consultant to the Royal Air Force.

In spite of the absorbing claims of his own practice as a consulting surgeon and his work at Bart's he found time for other activities. He became a member of the council of the Royal College of Surgeons in 1934, and was made Vice-President of the College in 1943. He had taken its Fellowship at the age of 26, in 1909 he had gained the Jacksonian prize for a dissertation on the treatment of surgical affections by vaccines and antitoxins, and he had been Hunterian professor in 1912. In the Royal Society of Medicine he was most prominently identified with the Section of Urology, of which he eventually became president, but he also took part in the general affairs of the Society, becoming successively honorary secretary and treasurer, and in 1938-40 succeeding Sir John Parsons in the presidential chair. Girling Ball was also a leading spirit in the organization of international conferences, and was the key man in at least one large congress of the kind in London. He had abounding energy himself and also the gift, which does not always go with it, of stimulating other people to energetic action.

He became a member of the British Medical Association in 1910, but apart from the appearance of his name as honorary secretary of the Section of Surgery at the Annual Meeting at Newcastle in 1921 he did not become closely identified with its work until recent years. In 1938 he became a member of the Central Medical War Committee, and in 1943 a member of its executive. He gave active help on a number of other Association committees concerned with the war situation, such as the emergency hospital organization, and release and demobilization of practitioners. He was a valued member of the Medical Planning Commission, making many useful contributions to its interim report. He was also on the original Representative Committee which engaged in the early conversations with the Minister of Health on the projected National Health Service.

In addition to the hospital work already mentioned, he was surgeon to the East London Hospital for Children in 1910-12; in 1910 he became surgeon to the Alexandra Hospital for Hip Diseases, and in 1934 to the Royal Masonic Hospital. He was consulting surgeon to the City of London Truss Society, St. Luke's Hospital for Advanced Cases, and the Foundling Hospital. He was the author of only one book, *Diseases of the Kidney*, published in 1932, which was written in collaboration with Dr. Geoffrey Evans. He wrote numerous papers on pathological and genito-urinary subjects, and his "cases from the wards" were a noteworthy feature of *St. Bartholomew's Hospital Reports*. He held the post of joint lecturer on surgery for many years, and as a lecturer his direct, refreshing style, untrammelled by notes, was very popular with students.

Girling Ball received the honour of knighthood in 1938 on the completion of the great work of reconstruction of his College. Had he not, at the age of 19, found his way through the gates of St. Bartholomew's Hospital he might have gone elsewhere in the city of merchant princes and have built up a great business organization, for he had true business instinct and the vision of a master builder. He was a likeable man, all the more so because of his impetuosity and forthrightness—a man who said what he had to say in the directest possible speech. Until his breakdown he appeared to have an enormous store of energy. He was very proud to be president of the Bart's Rugby Football Club, though he had long since betaken himself for recreation to the golf course. He will be remembered affectionately, and his death will be keenly felt, by generations of Bart's men.

A memorial service was held in the Church of St. Bartholomew-the-Great, West Smithfield, London, E.C.1, on Wednesday.

PROFESSOR ACHARD

Prof. Emile Charles Achard, the news of whose death on August 7, 1944, was delayed by the war, was born on July 24, 1860, in Paris, where he received his medical education, being a fellow student with the eminent surgeon Prof. Hartmann, who is still with us. He qualified at the Paris Faculty of Medicine in 1887 with a thesis on hysterical apoplexy. In 1910 he was appointed professor of general pathology and therapeutics, and in 1919 professor of clinical medicine. He was successively attached to the Beaujon and Cochin Hospitals in Paris. He held many other appointments at home and abroad, of which the most important were member of the Institut, Commander of the Legion of Honour, and general secretary of the Académie de Médecine. In 1937 he was elected Honorary Foreign Fellow of the Royal Society of Medicine, having been elected honorary member of the Clinical Section in 1933. He was also member of the Royal Academy of Rome, and had conferred on him the Order of the Crown of Italy.

Achard was a prolific writer. Besides many articles in Brouardel and Gilbert's *System of Medicine,* he was the author of works on typhoid fever, encephalitis lethargica, and oedema in Bright's disease, which was translated into English, on diseases of the blood, nervous system, kidneys, and suprarenals. He was also co-editor of *Archives de Médecine Expérimentale et d'Anatomie Pathologique.*

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Marmaduke Sheild Scholarships have been awarded to D. Bulmer, of Peterhouse, and R. P. Holmes, of Trinity College.

During the month of June titles of the degrees of M.B., B.Chir. were conferred by diploma on S. M. Martin, of Girton College.

UNIVERSITY OF LONDON

The title of Reader in Bacteriology in the University has been conferred on John Cecil Cruickshank, M.B., Ch.B.Ed., in respect of the post now held by him at the London School of Hygiene and Tropical Medicine.

The degree of D.Sc. has been conferred on A. C. Frazer, an internal student at St. Mary's Hospital Medical School.

UNIVERSITY OF SHEFFIELD

At a meeting held on July 13 the University Council received with regret the resignation of Dr. C. Gray Imrie, F.R.C.P., of the post of lecturer in physiology, and of Dr. J. MacA. Croll as lecturer in bacteriology, and accorded them its thanks for their services to the University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Moynihan Lecture will be delivered at the College (Lincoln's Inn Fields, W.C.) by Prof. Willem Noordenbos, Hon. F.R.C.S., professor of surgery in the University of Amsterdam, on Wednesday, Aug. 1, at 5 p.m. Fellows and Members of the College are invited to attend. Students and others, who are not Fellows or Members of the College, will be admitted on presenting their private visiting cards. Tea will be served before the lecture.

At a meeting of the Council of the Royal College of Surgeons of England, held on July 12, Sir Alfred Webb-Johnson was re-elected President, and Mr. C. Max Page and Major-Gen. W. H. Ogilvie were elected Vice-Presidents.

Prof. W. E. Le Gros Clark, F.R.S., was elected a Hunterian Professor for 1945.

The following appointments were made for 1946:

Hunterian Professors.—Mr. Ivor Lewis, one lecture on the Surgical Treatment of Carcinoma of the Oesophagus with Special Reference to a New Operation for Growths of the Middle Third; Mr. D. Hamilton MacLeod, one lecture on Endometriosis—a Surgical Problem; Lieut.-Col. B. W. Rycroft, R.A.M.C., one lecture on War Wounds of the Eye and their Modern Treatment; Lieut.-Col. A. L. d'Abreu, O.B.E., R.A.M.C., one lecture on War Surgery of the Chest; Wing Cmdr. W. D. Coltart, A.A.F., one lecture on Fractures and Dislocations of the Astragalus; Lieut.-Col. D. S. P. Wilson, R.A.M.C., one lecture on Missile and Traumatic Injuries of the Urethra and their Treatment; Major C. H. Gray, R.A.M.C., one lecture on Sciatica; Mr. S. H. Wass, one lecture on the Odontomes and Other Affections of the Jaws: their Pathology, Diagnosis, and Treatment; Mr. J. D. Fergusson, one lecture on Original Observations on Carcinoma of the Prostate treated with Oestrogens, based on a Study of Serial Perurethral Biopsies performed over Periods of from Six Months to Two and a Half Years during Continued Oestrogen Therapy; Mr. John Charnley, one lecture on the Conservative Treatment of Fractures of the Femoral Shaft; Major P. W. Clarkson, R.A.M.C., one lecture on the Treatment of Face and Jaw Casualties; Capt. C. G. Rob, *M.C.,* R.A.M.C., one lecture on the Diagnosis of Abdominal Trauma in Warfare.

Arris and Gale Lectures.—Profs. O. G. Edholm and H. Barcroft, two lectures on the Circulation in Human Skeletal Muscle; Mr. Norman L. Capener, one lecture on Physiological Rest.

Erasmus Wilson Demonstrators.—Six demonstrations on the pathological contents of the Museum, one by Mr. L. E. C. Norbury, O.B.E., two by Col. R. Davies-Colley, C.M.G., A.M.S., and one by Mr. T. M. Tyrrell, with ophthalmic pathological material. There are two vacancies.

Arnott Demonstrator.—Prof. A. J. E. Cave, six demonstrations on the contents of the Museum, to be combined with professorial lectures.

Beginning in the autumn of this year there will be a lecture in the College every Thursday at 5 p.m.

Subject to a satisfactory scheme being submitted, it was decided to seek power by Charter at a future date to institute a special Final Fellowship examination in oto-laryngological subjects. It was also decided to hold an additional Primary Examination for the Fellowship in January, 1946.

Sir Frank Colyer was reappointed Honorary Curator of the Odontological Collection; Dr. F. S. Cooksey was elected an additional examiner for Part II of the Diploma in Physical Medicine during the current collegiate year; and Mrs. H. P. Herbert was reappointed a Leverhulme Research Scholar.

It was decided to recognize the post of resident surgical officer at the Royal Infirmary, Oldham, for the six-months surgical practice required of candidates for the Final Fellowship examination.

Diplomas of Membership were granted to R. B. Broughton, R. A. Green, R. Hierons, and H. M. Wotzilka.

Diplomas in Psychological Medicine and in Laryngology and Otology were granted jointly with the Royal College of Physicians of London to the following successful candidates:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—J. A. Ainslie, W. H. Craike, J. Ff. Edwards, M. C. Hood, J. B. Randell, W. W. Roberts, H. A. Thorner.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—Géza Grünberger, J. L. Insley, A. A. MacGibbon, M. G. Marks, G. S. Midgley, G. H. Vawda, and H. Zalin.

Medical News

A deafness clinic has recently been established at the National Hospital, Queen Square, London, W.C.1. The work of this clinic will be devoted to the investigation and treatment by means of hearing aids and otherwise of deafness in all its forms, excluding those accompanied by active otitis media with ear discharge. Patients are seen, by appointment only, at 9 a.m. or 1.45 p.m. on Mondays, Tuesdays, and Wednesdays. All appointments should be made by application, telephone or letter, to the Deafness Clinic, The National Hospital, Queen Square, London, W.C.1. Terminus 7721.

In view of possible renewed negotiations with the Minister of Health, the Council of the Faculty of Homoeopathy feels that it is important to know the exact location of all physicians practising homoeopathy in the United Kingdom. Those not already in touch with the Faculty of Homoeopathy might contact the honorary secretary immediately at the London Homoeopathic Hospital, Queen Square, W.C.1.

A leave course for doctors of the U.S. and Dominions Forces, arranged by the Faculty of Medicine, University of Edinburgh, and the British Council, was held at Edinburgh from July 16 to 20. The programme included lectures by the professional staff and by Dr. Andrew Davidson, Chief Medical Officer, Department of Health for Scotland, and visits to medical institutions.

Negotiations have been completed between Lord Astor, the National Trust, the Bucks County Council, and various hospital authorities for converting to civilian use the Canadian military hospital on Lord Astor's estate at Cliveden. The hospital, which can accommodate over 700 patients, will be administered by the Bucks County Council. The Cliveden estate was given to the National Trust by Lord Astor in 1942, with an endowment for its upkeep.

At a meeting of the Hertfordshire County Council on July 23 reference was made to a proposal of the authorities of St. Bartholomew's Hospital to build a new hospital in the Watford area at a cost of about £1,000,000. The new hospital would probably have some 600 beds, and would include a medical school staffed by highly experienced consultant physicians and surgeons. The council appointed a committee to conduct negotiations with representatives of the hospital.

Capt. R. D. Mareth Timms, L.M.S.S.A., has been appointed Officer (Brother) in the Order of the Hospital of St. John of Jerusalem.

Dr. H. N. Ganguli, sub-assistant surgeon, Piphima, has been appointed M.B.E. (Civil Division) for services to the Forces in connexion with the Burma Campaign from May 16 to Aug. 15, 1944.

The Heberden Society, which was started at the British Red Cross Society's Clinic for Rheumatism, Peto Place, London, for the study of the rheumatic diseases, will in future admit as members physicians and surgeons actively interested in these diseases from any part of the country. Membership is limited to one hundred. Further particulars may be obtained from the hon. secretary, Dr. Kenneth Stone, 21, Wimpole Street, W.1. There will be a meeting extending over two days early in November to open the winter session.

A British Medical Exhibition arranged by the British Council was opened at the São Jose Hospital in Lisbon last month by the Portuguese Under-Secretary for Education. The exhibition included books and instruments, and British medical films have been shown. The Portuguese Minister of Education sent a message paying tribute to the work of the British Council and its Institutes in Portugal, and expressing the hope that more such exhibitions would be arranged. The British Minister, Mr. H. Ashley Clark, said that medical relations between the two countries were almost as old as the alliance itself, and that the exhibition showed that still more remained to be done in this field.

At a meeting of the directors of the Society for Relief of Widows and Orphans of Medical Men held on July 4, £2,047 10s. was voted for the payment of the half-yearly grants to the 55 widows in receipt of relief. A cheque was presented to Mr. Edward J. Blackett in recognition of his forty years' service as secretary. Membership of the society is open to any registered medical man who at the time of his election is residing within a twenty-mile radius of Charing Cross. Only widows and orphans of deceased members are eligible for relief. Full particulars and terms of subscription may be obtained from the secretary at 11, Chandos Street, Cavendish Square, W.1.

Owing to difficulties in dispensing, a demand has grown for the ready-packed sterile base suitable for preparing penicillin ointments. Arrangements have now been made by the Ministry of Supply, and three firms are able to offer a sterile ointment base in pots of about 1 oz. (i.e., 30 grammes) to which an appropriate quantity of penicillin solution can be added and readily incorporated. This is to meet hospital demands. The firms are: Boots Pure Drug Co. Ltd., Station Street, Nottingham; British Drug Houses Ltd., Graham Street, City Road, London, N.1; Burroughs Wellcome and Co., 12, Red Lion Square, London, W.C.1.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* measles notifications fell by 1,460, whooping-cough by 144, dysentery by 82, and acute pneumonia by 72; those for scarlet fever went up by 57, and for diphtheria by 37.

There was an increased incidence of scarlet fever in the counties round London, but little change elsewhere. The largest local variations in diphtheria were increases of 25 in Yorks West Riding, 23 in Durham, 13 in Warwickshire, and a fall of 14 in Lancashire; the rise in Durham was due mainly to an outbreak in Weardale R.D. 17. A fall in the incidence of measles was general throughout the country, although in Suffolk there was a rise of 47.

The incidence of dysentery, 210, was the lowest since December. The largest returns were those of Lancashire 49, London 38, Kent 14, Essex 11, Lincolnshire 11, Yorks West Riding 11.

In *Scotland* scarlet fever notifications went up by 38, and those of diphtheria by 14, but other infectious diseases fell by the following numbers: measles 84, acute primary pneumonia 37; whooping-cough 25, dysentery 14. The rise in diphtheria occurred in the east and south-east.

Typhus in Vienna

Typhus has been reported from Vienna. It has been stated by the Austrians that it has been impossible to remove garbage for some months, and large piles of refuse have accumulated everywhere.

Week Ending July 14

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,303, whooping-cough 1,098, diphtheria 422, measles 4,075, acute pneumonia 387, cerebrospinal fever 52, dysentery 206, paratyphoid 9, typhoid 10, poliomyelitis 12.

No. 27

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 7.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Binocular and Monocular Vision

Q.—*In a recent course on mental deficiency it was stated that very few people have centralized binocular vision, the image being usually distorted towards one eye, thus making that eye dominant, and that sometimes in a child with a specific disability in learning to read there was a condition of cross-laterality (e.g., left-handed but right-eyed, or vice versa), although it was also stated that there was no scientific evidence that this cross-laterality is the cause of the specific disability in learning to read. Could some more information be supplied as to the correlation of cross-laterality, and a simple experiment to detect the condition be indicated—such as would be possible to apply in a special school for dull children?*

A.—It is difficult to understand what is meant by centralized binocular vision. The question seems to be whether the people have straight eyes, in which case about 80% will have normal binocular vision, since statistics show that a very small percentage of people can maintain their eyes in a normal position without good binocular vision. If this is not so, then a squint is present, and this would be the same whether the patient is mentally deficient or not.

When binocular vision has not been developed, the dominant eye would be decided primarily by the refraction of the eyes. There is no evidence that right- or left-handedness has any real influence, in spite of an occasional case of left-handedness with a left master eye.

The possibility that a child may have diplopia could increase the difficulty of learning to read, but diplopia usually gives way to suppression of the second image, so that the child uses monocular vision. As no stereoscopic vision is required for reading, monocular vision cannot be accepted as a factor in the child's disability to read or write. "The image usually distorted towards one eye, thus making that eye dominant," suggests that the other eye in these cases either is amblyopic or is not accurately corrected with spectacles. A very careful refraction is necessary in mentally defective children, since the subjective test is of little value.

Shock and Haematemesis

Q.—*Has shock ever caused gastric haemorrhage?*

A.—It is assumed that "shock" is used to mean traumatic shock or wound shock. This may cause multiple focal lesions in the gastro-intestinal tract which are attributed to anoxic tissue necrosis secondary to vasoconstriction and which may give rise to severe bleeding. Emotional shocks may also be followed by haematemesis, more particularly in the patient who already has a chronic ulcer. This is because strong emotions are accompanied by extreme congestion of the gastric mucosa, as demonstrated by Wolf and Wolff (1943). Alvarez describes the case of an inventor who had six haematemeses in three years, each one associated with setbacks in the invention on which he was working.

Diphtheria Inoculation of Allergic Subject

Q.—*I vaccinated a baby aged 7 months. A week later he suddenly developed a severe urticarial type of rash and appeared acutely ill. The site of vaccination was normal and the arm not particularly inflamed, and I had no further trouble. The mother had asthma during her childhood, and she has another boy, who suffers from slight eczema of the hands and feet. The parents are anxious for the child, now 14 months old, to be immunized against diphtheria and whooping-cough, but are afraid of the possible reaction. Is this likely to occur with A.P.T. or with pertussis vaccine?*

A.—Allergic rashes after primary vaccination occur in a small proportion of children, and the family history in this case suggests that the allergic predisposition has been inherited. It would, therefore, be hazardous and unwise to give this child an injection containing an appreciable amount of a foreign protein: for example, if he were to develop diphtheria an injection of antitoxin might provoke a serious reaction or even prove fatal. On the other hand, the amount of protein in diphtheria toxoid is very small and immunization with A.P.T. should be a safe procedure. As a precautionary measure a preliminary Schick test may be done, and if there is a definite pseudo-reaction—i.e., a zone of erythema not less than 1 cm. in diameter at the sites of injection of both test and control material—immunization should be carried out cautiously, preferably with small frequent doses of formol-toxoid. The child should be under observation for 1 to 2 hours after an injection, and a hypodermic syringe charged with adrenaline kept handy. Immunization against pertussis, although very desirable, is still not sufficiently reliable to justify its recommendation in a child in whom the injection of a concentrated bacterial vaccine might elicit a rather sharp reaction.

Colostomy for Carcinoma of Rectum

Q.—*In cases of inoperable carcinoma of the rectum without obstruction, does a colostomy really give relief or does it only add another worry to the distressed patient?*

A.—In course of time a carcinoma of the rectum has an almost inevitable tendency either to occlude the lumen of the gut or to become ulcerated; sometimes it does both. When ulceration occurs sepsis comes in its train, and as a rule this is followed by a more rapid spread of the cancer. The performance of a colostomy well above the growth will prevent the supervention of obstruction, avoid the irritation of the growth by the passage of faeces, and so lessen the risk of haemorrhage, ulceration, and sepsis; it also enables palliative operations (such as the removal of portions of papillary growths or the application of radium) to be carried out in a cleaner field and with a better prospect of benefit. In growths which are already ulcerated the performance of a colostomy will often cause a great improvement in the local condition.

To a very small minority of patients the very idea of a colostomy is so repellent that they prefer to tolerate greater rectal discomfort to avoid this operation; with such patients the only absolute indication for colostomy would be severe mechanical obstruction. To most patients, however, the benefit of a properly performed colostomy outweighs its disadvantages, for if it be well cared for the patient can continue the ordinary avocations of life without undue discomfort.

Parathyroids and Calcium

Q.—*In man the parathyroids control the output of calcium from the store in the bony skeleton and maintain the constant level of the blood calcium. Is this parathyroid control found in all animals with bony skeletons?*

A.—The statement made in the question is correct for all mammals, although some experimental evidence suggests that the primary action is on the blood phosphorus.

Fitting of Smith-Hodge Pessary

Q.—*In fitting a Smith-Hodge pessary, would it be advisable in some cases to bend the upper end in such a way as to fit it in front of the cervix instead of in the posterior fornix? Would such a position be likely to cause trouble during menstruation?*

A.—The essential features of the Hodge pessary are its two curves specially designed to fit the vagina and the adjacent pelvic structure, and the rounded upper end to exert an evenly distributed pressure in the *posterior* fornix. It is used mainly in the treatment of retroversion, and the upward and backward pressure of its upper end on the vaginal wall *behind* the cervix, and on the overlying utero-sacral ligaments, holds the cervix backwards and thereby ensures that the fundus of the uterus will stay forwards. Although it is correct to adjust the length and width of a pessary to suit individual vaginae, if the curves were altered, and particularly if the upper end were placed in front of the cervix, the whole principle of the pessary would be destroyed. The same comments apply to the Albert-Smith pessary. If the idea is to bend the upper end of the pessary acutely forwards to form a loop to fit in front of the cervix and thus hold it backwards, then it should not interfere with menstruation. However, it is not likely to be so efficient mechanically as the standard Hodge or Smith pessary; it might cause the patient discomfort, and the sharp angles projecting into the posterior fornix might cause ulceration of the vaginal wall.

A Swallowed Button

Q.—*A girl of 11 swallows a button, without informing anyone of the event until three weeks have passed and without any indication of anything being wrong. Should an x-ray film be taken to see if it is in the alimentary tract, and if it is, what should be done?*

A.—A swallowed button of any shape or size should be allowed to pursue its way through the alimentary tract without interference from the medical attendant. There is, of course, no harm in satisfying natural curiosity as to the presence or position of the button by taking an x-ray photograph or by screening the abdomen, but in general the less fuss made about it the better. No harm is at all likely to come of it.

Value of a Drug

Q.—*I have prescribed syrup. hypophosph. co. and syrup. glycerophosph. co. for years. A new edition of a well-known book on therapeutics and pharmacology says there is no evidence that these preparations are of any value. Do you agree—apart from the psychological value of any "tonic"?*

A.—The statement in the textbook is that "there is no *evidence* that these preparations are of any value." It is one thing to say that preparations have no value, and another to say that there is no evidence that preparations have value. Syrup. glycerophosph. co. contains about 1/30 grain strychnine in a 2-drachm dose, and this alone will have some effect in promoting gastric secretion. Recently an investigation was made of the value as expectorants of the individual constituents of tinct. opii camphorata. To the surprise of the investigator a true expectorant action (of varying extent) was found to be possessed by every ingredient. But until this work was done "there was no evidence" that many of these ingredients had any value.

Climate and Tuberculosis

Q.—*Is the climate of Birmingham and Stratford-on-Avon likely to be deleterious to a tuberculous person, aged 60, accustomed to sea air and high altitudes (Davos) during the last 35 years? The patient had a mild attack 30 years ago (haemoptysis, positive sputum); no activity since. Skiagrams show "snow-storm" lungs and fibrosis and calcification, about one-third of the parenchyma being destroyed. For the past 35 years he has lived on the south coast; 14 years in general practice, 5 years in pathological laboratories.*

A.—Advice on suitable climates is always difficult. Many factors are involved. One recalls an elderly consumptive with extensive but non-progressive pulmonary tuberculosis and much bronchitis and emphysema, who could not live on the south-west coast but flourished at Skegness.

But one may generalize in this case, considering (*a*) that the pulmonary tuberculosis, on history, is unlikely to reactivate; (*b*) that the main dangers will come from bronchitis and emphysema and secondary epidemic catarrhal infections; and (*c*) that he has done very well on our south coast. The ideal climate should be: temperature dry and with the minimum of atmospheric pollution, such as is provided by South Africa at an altitude of 3,000 to 4,000 feet.

The patient has, however, done well in normal working environment on the south coast, and therefore it would be unwise to disturb this excellent result by a move to the less clement climate of the Midlands, especially if the move is into urban conditions. If the move is unavoidable, if the patient is his own master, much can be done by common sense: i.e., confinement to a warm fireside or even to bed during bad weather; avoidance of crowded places such as shops and cinemas during periods of epidemic catarrh, not forgetting the inevitable end of May and of September epidemics. The use of an "air-conditioned" bed-sitting-room can also be considered. During the winter such a patient usually knows when he wakes whether it is a "good" day or a "bad" day, and can plan his day accordingly. Wide-open windows in the winter should be eschewed. Ventilation and not exposure is the aim.

To sum up, treat the inevitable bronchitis and emphysema, or tendency thereto, and more or less ignore the underlying pulmonary tuberculosis.

Intestinal Antiseptics

Q.—*In the annotation "Intestinal Antiseptics" (*JOURNAL*, Feb. 3, 1945, p. 158) it is stated that "preparations which are not readily absorbed—e.g., sulphaguanidine . . .—are preferable to others which, being absorbed, may have deleterious effects on the kidney." In the* JOURNAL *of April 22, 1944 (p. 557), it was stated about sulphaguanidine that "when given by mouth two-thirds is absorbed from the gut before reaching the ileo-caecal valve, and that poor concentrations in the blood are due to rapid elimination in the urine and not to poor absorption." It is improbable that both statements can be correct, and it would interest me to know which one is the more accurate.*

A.—When sulphaguanidine is given by mouth about two-thirds is usually absorbed from the intestine. Consequently it is fairly readily absorbed (although less readily than most other sulphonamides, which are almost completely absorbed in the intestine), and the amount of sulphaguanidine requiring excretion by the kidney is practically as great as that of the other sulphonamides. On the other hand, sulphaguanidine and its acetyl derivatives are more soluble at the usual *p*H of urine—e.g., *p*H 6.8 (solubility of sulphaguanidine, 220 mg. per 100 c.cm. at 37° C., and of acetyl sulphaguanidine, 81 mg. per 100 c.cm.)—than are sulphapyridine and acetyl sulphapyridine (solubility approximately 50 and 30 mg.), sulphathiazole and acetyl sulphathiazole (130 and 12 mg.), and sulphadiazine and acetyl sulphadiazine (42 and 92 mg.). (See *J. Pharmacol.*, 1944, **81**, 17.) Sulphadimethyl pyrimidine (sulphamezathine) and its acetyl derivatives are comparatively quite soluble. Renal complications due to blockage by sulphonamide crystals are much less likely to occur during treatment with sulphaguanidine than during treatment with sulphapyridine, sulphathiazole, or sulphadiazine; nevertheless they have occasionally been reported in severely dehydrated patients—e.g., men with dysentery in a hot climate. Accordingly it is correct to state that sulphaguanidine is less dangerous to the kidney than many other sulphonamides are; but this smaller danger is due to its greater solubility rather than to its lower tendency to be absorbed.

INCOME TAX

Assessment of Practice here while Serving Abroad

"Q. X." was called up in November, 1942, and landed in India in May, 1943. A locumtenent was left in charge of his practice. The net profits of the practice—reduced, of course, by the earnings of the locumtenent—have fallen and the operation of the previous year's basis has resulted in demands for tax which have approximated to the amount of the profits. Can any relief be claimed?

⁂ Section 11 of the Finance (No. 2) Act, 1939, as continued by subsequent Finance Acts, provides for an adjustment "to the profits of the actual year where the actual earned income . . . is not more than four-fifths of the actual earned income as assessed for that year." This particular case is complicated by the fact that in ordinary parlance the "actual earned income" includes income—i.e., Army pay in India—which does not suffer British income tax. On that point the definition of "actual earned income" in subsection 7 (*c*) of the Section referred to above is relevant. That expression means "the amount of earned income that would be assessed and charged . . . if the amount were in all cases computed by reference to the actual income for that year and not by reference to the income for any other year or period." It will be seen that the emphasis is on the difference in basis, and the definition does not appear to us to justify importing into the comparison between "assessed" and "actual" income any income which is not liable to British income tax. On that basis the Section should provide the relief appropriate in equity to such a case as this.

Taking on a Partner

L. P. is selling a half share in his (sole) practice; how does this affect the basis of his assessment? He raises a further question as to what liability (if any) attaches to the new partner for the first year of the partnership.

⁂ (1) The assessment for this year will be made on the basis of the profits of the practice for the previous year—i.e., the normal basis. But if the profits of this year should fall short of the amount assessed the partners can claim to have the practice regarded as a new one as from the date of sale. In that case the assessment for the part of the year affected would be on the basis of the profits of the actual period. It will be seen that whether such an adjustment would be advantageous will depend on whether the increase in the gross earnings of the practice due to the advent of a second proprietor will be greater or less than the professional expenses incurred by that partner. Usually the advantage lies in allowing the previous year's basis to remain in operation. It is presumably understood that as from the date of the partnership the tax on the assessment is divisible between the partners—which normally operates in favour of the former proprietor.

(2) The previous year's basis of calculating the assessment applies to the practice and not to the individual partners. Assuming, for instance, that the new partnership started as from April 5, 1945, and that the accounts of the practice have been made up to December 31, then the position for the financial year ending April 5, 1946, will be as follows. The assessment, say, £3,000, will be divisible between the two partners on the basis of their shares in the practice, say, 2/3rds and 1/3rd, and they will be liable to account for tax on £2,000 and £1,000 respectively. The incoming partner does not get a tax holiday for his first partnership year.

Allowance for Ground Rent and Repairs

J. C. left his house in London five years ago, and no income tax has been paid on it since. He has been paying a ground rent of £45 a year and has expended £400 (apart from war damage) on repairs and maintenance. Can he claim an allowance for these payments?

⁂ *Ground Rent.*—If this rent is payable under a "long lease"—i.e., a lease granted for a term exceeding fifty years—J. C. was entitled to deduct tax from the rent under Section 17 of the Finance Act, 1940. In that case he might be well advised to inquire of the lessor whether he will now refund the tax which could have been deducted. (As the lessor is apparently entitled to exemption from tax he may then be able to reclaim the tax from the Revenue.) There is no other means by which J. C. can get any relief in respect of these payments. *Repairs, etc.*—The income-tax allowances are given against the tax payable on the property, and as no such tax was paid no relief can be claimed.

Salaried Appointment: Hotel Expenses

"X.Y.Z." held for a short time an appointment for which the remuneration was £700 a year, without board and lodging. His wife and children were living in another part of the country. Can he claim an allowance for the cost of his hotel accommodation?

*** No; the £700 is chargeable to tax, and the Income Tax Acts contain no provision under which "X.Y.Z." could claim a deduction for the additional cost of living resulting from his domestic circumstances and locality of the employment.

Return from India

J. B. returned from service in India, leaving India on July 6, 1944, from which date he received British pay at 24s. 6d. a day, increased by 2s. 3d. a day as from Oct. 18. What tax is he liable for in this country for the year ended April 5, 1945? He was married in May, 1945.

*** The calculation on the figures given is as follows:

	£	s.	d.	£	s.	d.
Amount of income (Service pay)	386	0	0			
Deduct uniform allowance	30	0	0			
				356	0	0
Less personal allowance (single)				80	0	0
				276	0	0
Of which £165 taxable at 6s. 6d.				53	12	6
and £111 taxable at 10s.				55	10	0
				109	2	6
Life assurance allowance, £54 at 3s. 6d.				9	9	0
Net liability				£99	13	6

Changes in Employment and Service in 1944-5

J. G. qualified in December, 1943, but his earnings for 1943–4 were below the exemption limit. From April, 1944, to August he earned £239 as a locumtenent and tax was deducted under P.A.Y.E. From Oct. 7 to the end of February, 1945, he served in the R.A.M.C. and tax was deducted at £7 per month. At the end of February he came on to Indian rates of pay. No refund of tax has been made to him since leaving civil employment.

*** The deductions of £7 per month by the Army authorities were evidently intended to be approximate, and subject to final revision—a revision which has not yet been made. In view of the fact that J. G. was not earning from the end of August to Oct. 7, it is practically certain that some repayment is due to him. Unfortunately tax offices are apparently at present in arrear with their work, and J. G.'s transference to the Indian Command may have caused still further delay in settling his British liability. A letter addressed to the Chief Inspector (Departmental Claims Branch), The Hydro, Llandudno, may help to expedite the matter. Full particulars of past employment and service in the R.A.M.C. should be given.

LETTERS, NOTES, ETC.

Patulin et al.

Mr. F. **BERGEL** writes: I read with interest your annotation "Pharmacology of Patulin" (*Journal*, June 30, 1945, p. 915). May I draw attention to a small error which occurred in your article. You say: "It appears to be identical with claviformin,[2] clavatin, and clavacin.[3]" Footnote 3 quotes: Wiesner, B. P., *Nature*, 1942, **149**, 356. I am afraid that this quotation does not contain any information as to the identity of the three preparations, but that the identity of claviformin with clavatin and patulin was published for the first time in a letter to *Nature*, 1943, **152**, 750, of which I attach a reprint. It would therefore have been correct to write footnote 3 after clavatin and to quote the above-mentioned letter to *Nature* under footnote 3.

Epilepsy and Menstruation

Dr. **MURIEL KEYES** (Harrogate) writes: For 20 years I was able to observe, unusually closely, a female epileptic; and detailed daily records were kept the whole of this time, *re* fits, emotional behaviour, and general health. Attacks did occur at other times, but they were most frequent just before or at the actual onset of menstruation; this was recognized by the patient herself and her attendant, also that any annoyance or emotional upset might provoke a minor or major attack. She was allergic to grass and flower pollens and the "tan" litter" used at horse shows, etc., and I often wondered whether either some allergy to one of her own hormones, or a temporary waterlogging of the pituitary, etc. (upsetting the normal cerebral circulation at a certain stage of the menstrual cycle) was the precipitating factor in attacks. Later, several patients with pre-menstrual distress and menstrual headache benefiting by treatment with ammon. chlor., I hoped to try this on a menstrual epileptic. In the gynaecological clinic of Mr. Alfred Gough I was permitted to treat such a case. A young woman, 35 years, reported with epileptic attacks of 6 years' duration, occurring only at the time of menstruation (which was preceded by painful breasts and pain in head). She was given 0.6 gramme of ammon. chlor. three times a day, starting on the fourteenth day from onset of each loss; as her periods are irregular (5–7-week intervals) she has to carry on from fourteenth day up to the onset of next loss; at this time no domestic salt or soda bic. is allowed. Beyond one slight fit in the first treatment course she has been entirely free of all "attacks" for 12 months, and this week reported to ask whether she might consider marriage. I am indebted to Mr. Gough both for the opportunity of treating this patient and for permission to publish the case. (See "Any Questions?" March 17, 1945, p. 396; and notes on April 7, p. 504, and May 26, p. 758.)

Sterilizing Paraldehyde

Mr. T. D. **WHITTET** (pharmacist, Charing Cross Hospital) writes: In the reply to the question on the sterilizing of paraldehyde (June 9, p. 829) it is inferred that paraldehyde cannot be sterilized by autoclaving. In a paper by Marston and Allchin (*Pharm. J.*, Nov. 7, 1941, p. 152) the following points were established: (*a*) Whilst paraldehyde is strongly bactericidal to non-sporing organisms, its action against sporing organisms such as the *Clostridia* is very slow, and hence paraldehyde for parenteral injection should be sterilized. (*b*) Paraldehyde can be autoclaved at 130° C. for 30 minutes without appreciable decomposition. (*c*) Paraldehyde for injection should be issued in glass ampoules since it attacks rubber caps. I have prepared several batches of paraldehyde ampoules and have tested them by the *B.P.* methods after sterilization and confirm the results published in the above-mentioned paper.

Fate of a Threepenny Bit

Dr. **NORMAN FLOWER** (Yeovil) writes: This record of a complication following an emergency caecostomy may well be unique. At the operation the caecum could not be delivered in order to build up a satisfactory "bottle-neck." A de Pezzer catheter, with the terminal cone cut off, was introduced. Drainage was good for the first few days, but gradually deteriorated in spite of constant syringing, and there was also a tendency to leak alongside the tube. The catheter was troublesome to withdraw, but with steady traction it suddenly came away with a jerk. Examination of the catheter at once revealed the cause of the obstruction. Snugly fitted into the cup of the de Pezzer was a black and very corroded silver threepenny bit, which had been exerting a pronounced valvular action. The patient admitted that he well remembered occasions on which all the threepenny bits in the Christmas pudding had not been accounted for!

Management of Persistent Occipito-posterior Presentations

Dr. A. H. **MORLEY** (Mill Hill, N.W.7) writes: There can be no doubt that the best treatment of this most disconcerting complication of labour is manual rotation to an anterior position of the occiput, usually followed by the application of forceps, but this may fail or, on occasion, be impracticable. Is there any means of minimizing or preventing extensive perineal laceration caused by the arrival of a head "face to pubes"? I suggest that there is. One most noticeable feature of this type of case is the refusal of the head to remain "crowned." It slips back in an aggravating manner between the pains. If, when the head is nearly crowned, a pad is applied to the stretched rectum the head can be "held," and during the interval between the pains appropriate pressure forwards will slowly deliver the head. In a recent case so delivered there was no tear, external or internal, though the child weighed 7¾ lb. The point I wish to make is that it is an obstetrically sound procedure, as it promotes *flexion*, and consequently tends to produce a smaller diameter for the vulva, if one is dealing with an occipito-posterior position. Conversely, it is a procedure to be avoided in a normal delivery, as it encourages extension and a large diameter.

Treatment of Plantar Warts by Injection

Dr. H. N. **ROSE** (Ilford) writes: The present accepted methods of treatment of plantar warts are: (1) repeated applications of caustics or caustic plasters; (2) curettage; (3) carbon dioxide snow; (4) *x*-ray application. None of these is consistently successful. Repeated applications of caustics are tedious and often painful. Curettage and carbon dioxide snow may prevent walking for several days, and facilities for *x*-ray treatment are not always easily available. During the past eight years over 120 cases of plantar warts have been treated successfully by a simple method of injection, not, I believe, previously described. A solution of 5% phenol is injected by means of a dental anaesthetic syringe and needle. An ordinary hypodermic syringe and needle does not develop sufficient pressure on injection to overcome the resistance of the tissues. After cleansing the skin and wart with ether, the needle is inserted intradermally into healthy skin about 3 mm. from the edge of the wart and thence into the deep portion of the wart. A total of 3 to 15 minims of the solution is injected, dependent on the size of the wart. In a large wart it is beneficial to perform several circumferential injections. When seen after 7 days the wart has shrivelled in size and is of bluish-black colour. After 3 to 4 weeks it has completely disintegrated.' If too much solution is used some may infiltrate below the wart or escape externally. In the former case a blister develops. This may cause slight discomfort on walking but has no effect on the ultimate result. The pain which most patients experience on walking is usually abolished by the injection. This method has also been successfully employed in cases of warts on the hands and fingers, including the flat warts which occur on the skin at the sides of the finger-nails. The mode of action of the injection may be due to any or all the following factors: (1) tissue necrosis of the wart, caused by the local toxic effect of the solution; (2) tissue necrosis of the wart by the disruptive pressure of the injection; (3) thrombosis of the wart's vasculature; (4) destruction of the causative virus by the antiseptic action of the solution. The successful use of other solutions is matter for research.

Chloroform Anaesthesia

Col. G. S. **THOMSON**, I.M.S.(ret.), writes: As I have only recently returned as, *en route*, specialist surgeon in charge of 797 "priority" evacuees, I am reading back numbers of your valuable *Journal*. In the issue for Feb. 19, 1944 (p. 263), are two letters on anaesthesia misadventure incriminating chloroform. The writers are young enough to omit all reference to India's magnificent Nizam of Hyderabad's Commission of Inquiry thereon. At the request and by the suggestion of Major Percy Benson, I.M.S., resident surgeon and medical adviser to the Nizam, Sir Lauder Brunton was invited to Hyderabad as chief investigator. The "open method" was in use successfully there for years; it involved no elaborate apparatus or technique: just a cone of sterile, stiff cardboard paper, one inch in diameter, open at its apex, with a 2-oz. plug of cotton-wool secured in position with a safety-pin. The anaesthetist kept a tongue forceps in the left lapel of his clean, white gown, poured one drachm of chloroform on the plug of wool, told the patient to count up to twenty and take deep breaths. In my 37½ years in India with 2,500 midwifery deliveries under the "open method" I lost only one European mother 5 hours after delivery due to embolism; she was a primipara, aged 25, of good physique, at full-term and had been six hours in labour. Chloroform enabled me to perform 106 suprapubic stone extractions with only one death—the 106th.

Acupuncture

Dr. T. **STACEY WILSON** (Birmingham) writes: In the reply given in the *Journal* of July 7 (p. 34) to a question about acupuncture no reference is made to the value of this method of treatment in certain cases of sciatica. Fifty years ago, when I was one of the honorary physicians at the Birmingham General Hospital, acupuncture of the sciatic nerve where it is palpable at the back of the thigh was a recognized method of giving relief to certain cases of sciatica. When the sciatic nerve is not only abnormally tender but can also be felt to be somewhat swollen and hard, there is a probability that the nerve sheath is distended with inflammatory exudation. In such circumstances the transfixion of the nerve with a large-size round acupuncture needle will allow the fluid to escape and give relief from pain. It was usual to allow the needle to remain *in situ* for 15 or 20 minutes in order to lessen the rapidity with which the opening in the nerve sheath would close after the withdrawal of the needle. When an inch or more of the sciatic nerve was felt to be swollen and hard two needles could be inserted three-quarters of an inch apart instead of only one. The relief given was so definite that if the pain recurred within a day or two the patient would ask for a repetition of the treatment. This method of treating sciatica had the advantage of making clear a case of malingering, for such a patient would not run the risk of having a repetition of the treatment.

Resuscitation after Drowning

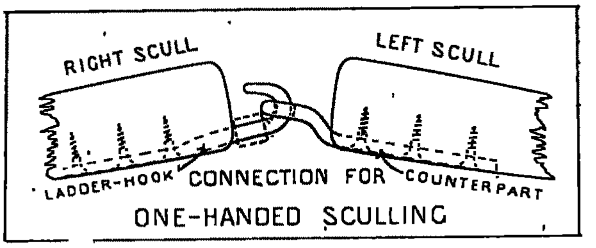
Dr. **JOHN YATES** (Cockfosters, Herts), writes: I have come across the following passage in *The Vicar of Morwenstow*, by S. Baring-Gould (published 1876). It describes the attempted resuscitation of a member of a shipwrecked crew. "We succeeded in getting hold of him at last, and brought him ashore. Unfortunately there was no doctor by, or any one who was experienced in dealing with cases of drowning. We did as best we knew, following the old usage of throwing him across a barrel." Is this a method of artificial respiration by rocking?

Relief of Tinnitus

Dr. G. C. **CATHCART** (London, W.1) writes: In the *Journal* of June 30 (p. 934) a correspondent asks a question concerning the treatment for relief of "noises in the head." The answer given was to try a course of short-wave diathermy coupled with the use of nicotinic acid and the usual sedatives. I have a short-wave diathermy machine and have given it a fair trial with no good results. I have also tried nicotinic acid and the usual sedatives with equally no good results. In the 2nd edition of my book, *The Treatment of Chronic Deafness by the Zünd-Burguet-Electrophonoide Method*, out of 665 cases of deafness there were 230 cases of tinnitus or "noises in the head," of whom 158, or 68.7%, improved after treatment. In 1934 I published an account (*Proc. roy. Soc. Med.*, **27,** 897) of 7 cases of deafness and tinnitus with relief of the deafness in every case and cessation of the tinnitus in 6 cases—a percentage of 85.

Sculling for One-armed Men

Dr. **PERCY TATCHELL** writes: Experiments on the Thames have shown that it is feasible for a man who has lost an arm to row two sculls. The plan adopted is to connect the scull handles together with a strong hook and eye (see diagram). The user rows one oar in the ordinary way, the other is a trailer, and dips and feathers in unison with the master oar. The leathers, well greased, draw in and out on the sills. Steering is effected by moving the hand to the side, thus lengthening one oar and shortening the other, the buttons having been removed. The eye should be on the sound side.



Ergot and Abortion

Dr. **ARTHUR J. AMBROSE** writes from Paignton: In the report on disciplinary inquiries made by the G.M.C., published in the *Supplement* of June 9 (p. 105), occurs the following statement: "He gave liquid extract of ergot and this failing he inserted an instrument." Years ago the late Dr. G. E. Herman, author of that classic *Difficult Labour*, also wrote a less-known work, *Diseases of Women*, in which he stated that ergot did not cause abortion. I attended many women in full-term labour who told me they had taken ergot in unsuccessful attempts to terminate pregnancy—so my experience coincides with Herman's. But apparently magistrates, coroners, expert pathologists, and the G.M.C. think differently, as I heard a London coroner and a distinguished pathologist concur in this opinion. Legally if anybody administers any drug with the intention of procuring abortion he is guilty of a felony; but if the drug be one that has been proved to be ineffective, surely it ought not to be included in the list of abortifacients, and I should like to hear the opinions of expert pharmacologists and gynaecologists on this subject. It is not generally known that salicylate of soda—although it has no action on the pregnant uterus—is extremely useful in cases of delayed menstruation, relieving the pain and anxiety of a patient who erroneously thinks she is pregnant by establishing the flow. Incidentally, sod. sal. relieves "after-pains."

Fluorine in Toothpaste

Capt. **LINDSAY H. WALKER**, S.A.M.C. (Transvaal), writes: In "Any Questions?" (March 10, p. 355) a question appeared under the heading "Fluorine in Toothpaste," which referred to a leading article on fluorine and dental caries (April 1, p. 461). The questioner queried the danger of mottled enamel appearing from excess fluorine, and the *Journal* commented on the fact that this does not occur after calcification of the teeth is complete. Surely the most important fact is that excessive fluorine after dental calcification is complete leads to precipitation of calcium salts in joints and tendons with eventual ankylosis, as has been demonstrated in this country among both European and Bantu subjects exposed to daily ingestion of fluorine in drinking-water. The article by L. Spira, "Some Epithelial Changes in Fluorosis" (*J. Hyg.*, Camb., 1944, **43,** 400), should surely cast some doubt on the advisability of adding fluorine to such an everyday article of "diet" as toothpaste, and perhaps also bring into question the proposal to add penicillin, or any other product (natural or otherwise) to toothpaste, throat tablets, etc.

Reviving the Newborn

Dr. A. P. **GREEN** (New Malden, Surrey) writes: When I was a student at University College Hospital some thirty years ago we had a most useful way of promoting breathing in newborn infants. The procedure was to dip the forefinger in brandy and insert it up the baby's rectum. The effect is quite dramatic.

Local Sulphonamide Therapy

Capt. P. K. **RENSHAW**, R.A.M.C., writes: With reference to your answer to a question on local sulphonamide therapy (June 9, p. 830), may I draw attention to the following articles which suggest methods of desensitization and prevention of sulphonamide sensitivity: Erskine, D., *Lancet*, 1942, **2,** 568; Tate, B. C., and Klorfajn, I., ibid., 1944, **2,** 553.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 4 1945

PROBLEMS OF NAVAL WARFARE UNDER CLIMATIC EXTREMES*

BY

MACDONALD CRITCHLEY, M.D., F.R.C.P.

Senior Neurologist, King's College Hospital; Physician to Out-patients, National Hospital, Queen Square

PART I.—LECTURE I

In these lectures an attempt will be made to show how medical research, especially during this war, has assisted the Royal Navy in its function of engaging the enemy in every type of climate. My task is rendered difficult by the fact that for considerations of security one is debarred from referring to the very numerous and important researches which have been prosecuted since the war began. These lectures, therefore, stripped of the names and labours of the many research workers in Australia and the United States, as well as at home—especially in the Medical Research Council—will appear, for that reason, bald, discursive, and unscientific. The full story cannot yet be told.

Prevention of tropical and cold-weather disorders will not be discussed, for it is intended to concentrate on three climatic aspects of naval medicine—namely, (1) naval construction; (2) clothing; and (3) efficiency. Under the first heading will be discussed how naval architects enable a ship's company to tolerate both high and low temperatures. This section will also deal with such problems as the cooling of ships, ventilation, and, in short, general habitability. The second heading will concern the modern science of clothing as an ideal means of protection against environment—"ideal" when one is mindful of the Service restrictions imposed by considerations of appearance, ruggedness, and economy in bulk. Lastly, one will discuss the impairment of efficiency under unpropitious environmental conditions; the subtle ill effects which are attributed to long service in polar or tropical waters; the selection of those best fitted to stand up to Arctic or tropical service, and the early identification of those inherently unsuited for duty under such stresses.

On looking back over naval medical history, it is clear that the sea-surgeons of Great Britain during the eighteenth century were in many respects well ahead of their colleagues ashore and that their observations were pioneer efforts in preventive medicine. But in the nineteenth century the French marine was conspicuous not only in the early adoption of steam and of ironclads but by reason of its hygienists. One recalls the excellent work of Fonssagrives and of Méricourt in this connexion and their great interest in the increasing problems of ventilation. But, all along, naval medicine can be visualized as the closest approximation to what we now choose to call social medicine, for in the Service the total environment of our personnel comes under the closest study and care of the medical branch.

NAVAL CONSTRUCTION

Ventilation has always constituted a difficult problem in ship construction. In the early days seamen relied upon natural ventilation, which later was made to supply spaces below decks by means of wind-sails and scoops, down-take shafts or "aspiratories," to which was afterwards added a system of uptakes. Artificial ventilation eventually becomes imperative. While Desagulier's fans were being installed in the House of Commons in 1734, attention was drawn to the heavy sickness rate in the fleet at Spithead. To combat this it was suggested that the Desagulier system should be incorporated within one of the ships, but the idea was turned down by the Naval Surveyor.

About that time a Mr. Sutton became interested in marine ventilation, but could not secure the sympathy of the authorities. "*I particularly remember,*" he wrote, "*that being at a coffee-house near the Admiralty, I placed myself nigh some gentlemen of the Navy, and inquired of them, as I had before of others, as to the usefulness of a change of air; all, to a man, acknowledged it would be of the utmost service. I told them I could procure it; upon which one of the company went to another table and the rest followed him; and I heard him tell the others that he heartily pitied me, as being really mad and out of my senses.*" Within a few years, however, Hales's bellows ("ship's lungs") were used to circulate air throughout naval vessels. Various other mechanical systems were tried, including some which worked automatically with the roll of the ship. By 1873 the plenum principle had been introduced into monitors, and though reported upon unfavourably by Surgeon McCarthy, became adopted as the basic scheme for ventilation throughout ships of the Royal Navy.

It is obvious that both naval and civil engineers were preoccupied at that time with the question of odours from stagnant water in the bilges and vitiation of the air from animal exhalations and fumes and gases of various sorts. Later they spoke in terms of CO_2. Only to a lesser degree was humidity considered, while the temperature of the environment was rarely, if ever, discussed.

Ventilation

The 1910 conference on tuberculosis in the Royal Navy led to an Admiralty Committee on Ventilation, which submitted its final recommendations in 1914. A minimum supply of 3,000 cu. ft. of air per man per hour was required. As an index of adequacy of air supply it was enacted that samples of air from any living-space must always contain less than 0.12% CO_2. Cubic space should not be less than 20 cu. ft. per man in sleeping-spaces, with a gap of not less than 20 in. between hammocks. A temperature of 55 to 60° F. was aimed at for living-spaces in cold weather. But the inter-wartime period was one of great mechanical achievement, so that the expansion in both matériel and personnel always outpaced the adequacy of air supply. It was evident that some of the standards set could not in practice be attained. In 1937 it became necessary to appoint a further Ventilation Commission. As the desired 3,000 cu. ft./man/hr. had proved unattainable, they tried for a standard 2,000 cu. ft., insisting that the volume should never be less than 1,500 cu. ft./man/hr. (i.e., a change of air every five minutes). They found it impracticable to lay down a definite minimum cubic space per man in sleeping-quarters, but advised that there should be a distance of at least three feet between the mouths of the sleepers. This could be obtained in the case of hammocks by slinging alternately head to foot. The use of punkah louvres, which had gradually come about since 1912, was approved; but for cold weather (when the openings were often sealed), an additional relief vent, suitably baffled, was suggested. Mess-deck temperatures of between 60 and 65° F. were recommended for cold climates. The committee was concerned with the obvious inefficiency observed in cordite-handers under action conditions during the Mediterranean summer and the improvement when coolers were installed. The inference, however, was that cordite fumes were responsible, and coolers were advised only as an interim measure until some kind of non-porous containers for the cordite charges could be issued. Air-conditioning was discussed and was envisaged as beneficial, but, because of size, weight, and cost of the plant, was not regarded as an essential requirement.

---

* Being the Croonian Lectures delivered to the Royal College of Physicians, July 10 and 12, 1945.

With the onset of this war the recommendations of the second committee became out of date. Conditions within living- and working-spaces changed for the worse. All ships now carry a complement far exceeding the original design, in some cases by as much as 60%. Ships remain at sea for inordinate periods, and operational needs dispatch them to regions where extremes of climate add to the discomforts, unlike the peacetime cruising practice. Darkening ship demands a sealing of all scuttles after nightfall. The menace of air attack necessitates additional high-angle armament and radar equipment, which all means more men. Dangers of fire led to the removal of woodwork, and hence the sacrifice of the lagging or insulating lining of the ship's sides. (This is a practice which has come and gone according to the fluctuating policies of the last 60 years at least.) Finally, the risk of losing the vessel from rapid flooding after enemy action has been met by an elaborate system of "damage control" whereby the ship, immediately action is joined, is divided into a large number of air-tight and water-tight compartments. As soon as a ship enters dangerous waters it is battened down and hermetically sealed, the personnel standing by at first or second degrees of readiness. Ventilation suffers drastically. Indeed, in some compartments, such as the magazines and shell-handing rooms, circulation of air ceases. A steady rise of temperature follows, which in the Tropics may attain potentially dangerous levels.

Hence there arises a clash between two conflicting policies. On the one hand there is the operational need for keeping a ship afloat even after severe underwater damage. To effect this, damage control aims at converting the ship into something like a honeycomb. On the other hand there is the hygienist's concern over the personnel and their discomforts, the menace to their health, and the toll on their fighting efficiency.

First among the defects of habitability that accrue from battle conditions during this war are the *high temperatures* below deck, especially in the Tropics. Even in cold climates mess spaces tend to develop a temperature well above that outside, and a man coming off watch on the bridge passes from extreme cold to an atmosphere of hot, moist, and stagnant air. In the Tropics the conditions are worse. With an ambient air temperature of 85 to 100° F. (dry-bulb) the compartments where men work, eat, or sleep reach temperatures around 85 to 95° F. (wet-bulb). Consequently men strip except for shorts and sandals. Sweating continuously and profusely, most of them develop prickly heat, and often superadded septic or fungous infections.

Even more significant than raised temperature is *high humidity*. This feature may be conspicuous even in the Arctic, where the internal warmth, contrasting with the icy-cold uninsulated ship's sides, causes water of condensation to stream down on to the deck. Added to this is the moisture from wet duffel coats and oilskins which hang up to dry in the mess-decks. The question of humidity has exercised the medical branch for years, for cleanliness demanded frequent washing and holystoning of the decks, and this by evaporation produced a high water content of the air. To-day the question mainly turns on the lack of drying-spaces, with the result that wet garments are constantly hanging in places where men sleep. In the Arctic it is the wet top gear which is at fault; in the Tropics the shorts and singlets, which require at least daily dhobying.

Overcrowding from expansion in ships' complements may be endurable in the Arctic, as the heat engendered helps to warm the air. But in the Tropics it is a serious matter, affecting comfort as well as health. The cubic capacity allotted to a man may be far below the old minimum standard of 200 cu. ft. As many as possible sleep on the weather-decks, but this is usually impracticable at sea. At action stations working-spaces are grossly congested, and gun turrets, radar and wireless cabinets, transmitter stations, and so on may be crowded with personnel on watch, standing by, or dozing.

In cold climates there is the problem of *exposure* of watch-keepers. Men on look-out, on the bridge, or in control tops may be unprotected against driving sleet, high winds, and temperatures far below zero. How to keep alive—let alone alert—is not an easy problem.

All these are medical considerations which tie up with inadequacies in ship construction. Though far from novel, most have been greatly increased by the changing trends in modern naval warfare. That is why no serious attempt has been made to correct these defects until recently.

To investigate the problems in the widest fashion, and to justify any sweeping changes which may seem called for in the construction or ventilation of fighting-ships, the Admiralty in 1943 requested the R.N. Personnel Research Committee to appoint a Habitability Subcommittee. At once gaps in our knowledge became evident. There is the question of whether efficiency falls as environmental temperature and humidity rise, and of whether any such change is a progressive one. It was actually quite difficult to furnish the required answers or to make recommendations. The wide ranges of climate mean that naval engineers would have to raise the interior temperatures considerably in the Arctic, and lower them—if possible—in the Tropics, in order to maintain the efficiency of the personnel. Too exacting requirements on the part of the medical branch run the risk of being rejected out of hand as unreasonable. Moreover, there was the question of what we should use as a yardstick to measure habitability: should we speak in terms of dry- and wet-bulb temperatures, atmospheric humidity, katathermometer cooling power, or effective temperature?

This last seemed most promising, for it accords with modern ventilation practice, and embraces both dry- and wet-bulb readings and measurements of air movement. There are certain weaknesses, however, in the conception of effective temperature. It does not allow for acclimatization. It does not cater for men engaged in physical work. It is an empirical standard drawn up from the work of a relatively small series of Americans, whose ideas of environmental comfort might not be ours. Its validity in the higher ranges of temperature and air velocities has been impugned. The chief drawback is that it is inapplicable when there are sources of radiant heat—which actually is a characteristic feature in warships.

On the advice of Dr. T. Bedford, the Habitability Subcommittee has provisionally adopted Vernon's "globe thermometer" for use in ships, as it can be employed for measuring the radiant heat from the surroundings. Globe-thermometer readings, therefore, replace dry-bulb readings in the effective temperature charts, and the result is spoken of as "corrected effective temperature" or (C.E.T.).* Air velocities are determined by means of the silvered (high-temperature) dry katathermometer.

To comply with the standards of the Habitability Subcommittee for ships serving in the Tropics considerable changes might be required in the methods of ventilation. In new ships, and ships still on the stocks, drastic changes might be feasible, but in those already commissioned, and especially in the older ones, it is more a question of "patching up," as operational requirements take precedence and the ships cannot immediately be spared for dockyard hands. Some of the changes in mind could be made immediately; others would have to wait until the opportunity arose for a refit; others were still for the future.

The terms "tropicalization" and "arcticization" of ships are sometimes applied to the measures adopted to render vessels habitable in extremes of heat or cold. Though the methods are of recent origin, the idea is an old one. For many years special ships have been constructed for polar expeditions. "Tropicalization" would seem to be a newer conception, but we find the project being undertaken as long ago as 1740, when Commodore Anson made structural alterations in a squadron for the Pacific; and in 1841, when Dr. David B. Reid and Captain H. D. Trotter built ships for the Niger River exploration with extra ventilation and the introduction of "medicators."

---

* The effective temperature scale is referred to the standard conditions of still and saturated air, so that the effective temperature of an environment indicates the temperature of still air saturated with water vapour, in which an equivalent sensation of warmth was experienced in a long series of tests. When the reading of the globe thermometer is used to arrive at the corrected effective temperature (thus applying a more or less adequate correction for radiation) the standard of reference is an environment in which the air is still and saturated with water vapour, and in which the surrounding surfaces are at air temperature.

The *Victor Emmanuel* was the first hospital ship to be specially equipped for tropical service during the Ashanti War.

Air Conditioning

Chief among the items envisaged in modern tropicalization and arcticization are: the installation of air-conditioning plant; a return to the practice of lagging or sheathing; more extensive insulation of steam-pipes and other heat-producing machinery; reduction in C.E.T. by drying the air or by increasing air movement; the correction of the more obvious faults in the siting of intakes and exhausts (faults which had often resulted from structural alterations long after a ship's commissioning); and, finally, a general indoctrination of naval officers of all branches in matters pertaining to ventilation and habitability.

Air conditioning might appear at first sight to be the complete answer to all these problems, for incoming air is automatically cleansed, dried or moistened, warmed or cooled, as required. The problem bristles with difficulties, however. Air-conditioning plant is scarce, bulky, and heavy. Even were sufficient apparatus available for immediate installation, it would occupy so much space in a ship and add so much to the weight that fighting efficiency would suffer. Thus, to air condition a warship might require a great deal of extra weight and space—perhaps as much as a heavy gun and its turret—as well as several extra hands. This addition to an already congested ship means the sacrifice of some part of the existing offensive or defensive equipment. Whether such a policy is a business proposition which will pay dividends in the way of enhanced human efficiency is still a matter of conjecture rather than knowledge.

If one compromises by adopting air conditioning only in certain regions of a ship a fresh problem arises as to which spaces should be so equipped. Is it better to cool the working compartments (in order to ensure vigilance and accuracy) or the mess-decks (to afford a refreshing spell of sleep before the hands go on watch)?

There are other medical and paramedical problems. If air conditioning is to be the rule, what standards of temperature and humidity should be adopted with reference to the outer air? The phenomenon of "cold shock" is known to occur on passing abruptly from a tropical climate into a much cooler environment—as, for example, on entering a cold-storage room. An undue dryness of the inspired air is believed to produce an unhealthy state of the mucous membranes, as in the case of American railroad employees. Again, are ill effects to be expected from changing many times daily from one sort of environment to another? Thus, are upper respiratory infections facilitated by frequent changes from a hot humid to a relatively cool dry climate, or vice versa? What is the effect upon the process of acclimatization? Can it be that men conditioned to a tropical climate suffer as the result of a sojourn of some hours daily in an air-conditioned room?

Even more important is the risk that re-circulating air may increase the incidence of air-borne disease, quite apart from the possibility that an artificial climate may alter the virulence of droplet infections or the relative immunity of the occupants, or both. The use of chemical disinfectors or ultra-violet treatment of the incoming air needs careful thought.

Cooling or heating the incoming air may of course turn out not to be the ideal for naval purposes, and possibly the so-called "radiant reflective conditioning" might prove better. In this system the air is unaltered, but specially cooled (or heated) panels let into the bulkheads bring about the necessary thermal change in the occupants. This practice has not yet been tested in ships.

Some of these questions are, or will be, the subject of specific inquiry in our research laboratories in this country and those to be erected in the Tropics. Nevertheless we believe we have been justified in installing cooling plant in certain places in certain ships. As regards the temperatures at which they are maintained, we believe the tendency is to keep them too cool. It is rarely necessary, or indeed wise, to reduce them below an effective temperature of 78° F. (with a high outside temperature). An alternative ruling is to accept no more than 10° F. difference in temperature between the treated and the untreated air; or to adopt the Mayer-Fittz formula. The last word on this subject is still to be said.

Interim reports on air-conditioned compartments are most encouraging, though scientific data as to output and efficiency are not yet available.

Reducing the dry-bulb readings is only one way, of course, of lowering effective temperature, and something might be done in this direction either by decreasing the humidity or by increasing the movement of the air. The former can be brought about by means of various types of dehumidifiers or by silica gel desiccators. Both methods are used in the Service for the drying of certain compartments, and the practice has materially extended since the war. Both systems have drawbacks which prevent them from being adopted more generally, not the least being the fact that the act of withdrawing moisture from the air in itself generates heat.

Increasing the air movement is a much more practicable means of reducing effective temperature, and the improvement in comfort and efficiency is beyond what might be expected from the change in effective temperature. In H.M. Ships air movement is obtained below decks first by the blower system of ventilation and secondly by means of table, bracket, or punkah fans. In the blower system air is driven along trunks by means of electric fans and injected into the compartment by way of punkah louvres. This is in effect a miniature "spot-cooling" system, which on a larger scale proves so successful in making engine- and boiler-rooms tolerable despite the very high temperatures. In some locations—e.g., machinery spaces, galleys, heads—there is a forced-exhaust system, but elsewhere the peacetime practice was to rely upon natural means of exhaust—i.e., hatches and scuttles. Since this war, however, these natural vents are sealed.

The obvious way to improve habitability in ships under wartime conditions, especially in the Tropics, would be an increase of the air flow in volume and velocity. This would be an easier task than to cool the incoming tropical air to tolerable levels. Greater air movement could be obtained by increasing the size, the number, and the speed of fans in the trunkings; by providing more table, bracket, or punkah fans; and by installing exhaust fans in those compartments which used to rely on natural vents.

Other Methods of Increasing Habitability

Other methods of increasing the habitability of ships in climatic extremes may be mentioned briefly. The great sources of wild heat must be shut off from the rest of the ship by means of thermal insulation. The risk of fire precludes the use of wood except to a limited extent. Newer insulating materials have been introduced with various advantages. Hawkyns used a layer of tar and hair between two layers of wood—a practice which lasted till the end of the eighteenth century. The aluminium foil which is the most usual intermediate layer can now be replaced by far lighter plastics which are non-inflammable. These plastics still require an inner sheathing, however. A more extensive use of cork would combine the properties of thermal insulation with protection against the spread of fire. One of the most difficult regions of a ship to render habitable is a gun turret, which in the Arctic is bitterly cold, with its masses of steel and its water of condensation, and which in the Tropics is almost intolerable by reason of solar radiation. An attempt at a solution of the problem lies in the use of layers of cork inside the turret.

The sheathing of steam-pipes is being improved, especially where they traverse mess-decks. Steam leads, which add so much to the atmospheric humidity below decks, require stricter sealing.

The choice of appropriate colours in painting the hull and superstructure of ships is a problem of camouflage, but it has a medical bearing also. In the Tropics white paint reflects solar radiation best of all, while black absorbs most heat. Black pigments do not all behave alike, however, and radiation studies reveal that the composition of the paint may be as important as the colour as regards its reflection and absorption of infra-red radiation. Thus aluminium paints are the most efficient reflectors of the sun's rays.

Artificial lighting of the mess-decks contributes to the final temperature. Two 60-watt lamps produce rather more heat than one resting man. It is possible that fluorescent lighting might render a mess-deck cooler in the Tropics. Modern improvements do away with the disadvantage of the former feeling of the blue colour.

There is also the point whether the colour of the sides of the mess-deck has any effect upon the *feeling* of warmth or of coolness, even though this may operate through suggestion only. It has been the tradition to paint the interior of sick-bays a pale green in tropical-going ships. F. C. Houghton, H. T. Olson, and J. Suciu found no objective change in skin temperatures in different coloured environments, but they affirmed that occupants might experience a subjective sense of warmth or of coolness in the presence of this colour or that—which, from the human standpoint, is significant.

Body-cooling in hot atmospheres may be obtained by adequate draughts of cold water; in any event the need for drinking, over and above the call of thirst alone, is important for maintaining mental and physical efficiency in high temperatures. There is a rationale, therefore, for supplying cooled drinking-water in working- and living-spaces, though the American habit of iced water may not be a physiological ideal. Whether the water should contain salt or oatmeal needs closer investigation.

Lastly, the innovation of laundries in H.M. Ships has much to recommend it, not only because they promote cleanliness (and so avert skin infection) and avoid the wearing of sweaty garments (which aggravates prickly heat), but chiefly because they abolish wet garments from the mess-decks. There is the point, too, that sweat-soaked garments will not readily dry except in an atmosphere of extreme desiccation—a condition which does not obtain in the mess-decks.

(*These lectures will be continued in the issue of Aug. 11 and completed in that of Aug. 18*)

BACTERICIDAL EFFECT OF MIXTURES OF ETHYL ALCOHOL AND WATER

WITH SPECIAL REFERENCE TO STERILIZATION OF THE SKIN, AND A NOTE ON THE COMPARABLE EFFECTS OF ETHER

BY

G. T. L. ARCHER, M.B., B.Ch.
Lieut.-Col., R.A.M.C.

Although much work has been done by a number of observers on the antibacterial effects of alcohol on the one hand and on the value of various substances as sterilizing agents for use on the skin on the other, agreement would appear not to have been reached regarding the optimal dilution of alcohol for use on the skin before puncture or surgical incision. Precision on two points is necessary for a final assessment: first, percentages of alcohol in water should be accurately defined in respect of any observations made; and, secondly, the requirements of a fluid for use on the skin should be considered in terms of its physical properties as well as its bactericidal power. Further, due consideration must be given to the bacterial species which it is most necessary to eliminate.

Percentages of Alcohol

For scientific accuracy it is probably desirable that the strength of an alcohol mixture should be recorded as percentage by weight. On the other hand, under ordinary conditions the preparation of volumetric percentages can more readily be carried out. There are appreciable differences in the strength of mixtures produced by (*a*) making up a measured volume of alcohol to a total volume by the addition of water; (*b*) making up a measured volume of water to a total volume by the addition of alcohol; and (*c*) mixed measured volumes of the two fluids. These differences are due to concentration during admixture. The *first* is the correct percentage by volume. The following figures, calculated from tables given in *The Chemists' Year Book, 1942*, illustrate the differences in strength between solutions made up by the methods referred to:

(1) 76% by weight is approximately equal to 82% by volume, at 60° F.
(2) 70% " " " " 77% " " "
(3) A mixture made by making up 30 parts of water to 100 parts by the addition of alcohol is approximately equal to 73% by volume.
(4) A mixture made by the addition of 30 parts of water and 70 parts of alcohol is approximately equal to 72.5% by volume.

Physical Properties of Alcohol-and-Water Mixtures

From a practical point of view *surface tension* is probably among the most important variable characteristics of alcohol-and-water mixtures. It is likely that low surface tension is the factor mainly responsible for the improved spread (Bonney and Allen, 1944), penetration (Lovell, 1945), and complete wetting observed when alcohol is used on the skin. The variation in surface tension which occurs as alcohol is progressively diluted with water is illustrated by the following experiments. It was also apparent in some of the experiments on plates of solid media referred to later in this paper.

Experiment A

Mixtures of water and alcohol of 65 volumes of alcohol and 35 volumes of water, and of 30 volumes alcohol and 70 volumes of water respectively, were dropped from a Dreyer's pipette on to a porcelain tile which had been rubbed over with Congo-red powder. The diameters of the circles of spread of the alcohol were measured and the volume of the drops calculated by counting the drops in 0.5 c.cm. The mean diameter of the area wetted by the drop of the stronger mixture was 2.7 cm. (mean of 10 observations), while the mean volume of the drop was 16.6 c.mm. The figures for the weaker alcoholic mixture were 2.05 cm. (mean of 10 observations) and 19.23 c.mm. respectively.

Experiment B

A somewhat more careful observation, using absolute alcohol and a mixture of 65 volumes of alcohol and 35 volumes of water respectively, was made by tracing the outline of the wetted areas produced on a similarly prepared tile, measuring the areas enclosed, and calculating the diameter. The drop volumes were obtained by measuring the volume of 200 drops of each strength of alcohol. In this experiment the mean diameter of the area wetted by 16.375 c.mm. drops of absolute alcohol was 3.37 cm., while that of the area wetted by 17.625 c.mm. drops of "65%" alcohol was 2.85 cm.

Species of Pathogenic Bacteria Liable to be Found on the Skin

Bacteria encountered on the skin may be divided into "resident" and "transient" organisms. The former cannot be completely eliminated by any process which will not injure the tissues (Colebrook, 1941). Much of the "resident flora" is located in the pilonidal follicles; these are not penetrated by 70% alcohol or by acetone (Lovell, 1945). According to Colebrook (1941) *Str. pyogenes*, *Proteus*, and *Ps. pyocyanea* are among the transient flora, and *Staph. pyogenes* is difficult to place, being intermediate between the transient and resident flora. He quotes various workers as finding *Staph. aureus* (*pyogenes*) on the skin of from 5% to 30% of normal individuals. Martin (1942) reports the occurrence of *Staph. aureus* on the face, wrist, and chest respectively in 38%, 24%, and 14% of normal individuals, the corresponding figures of *Str. pyogenes* being 5%, 3%, and 1%. Miles *et al.* (1944) report the skin carriage of *Staph. aureus* in 18.4% of individuals. Cruickshank *et al.* (1942) quote Lockemann *et al.* (1941) as finding *Staph. aureus* more resistant to all strengths of alcohol than either *Bact. coli* or *Ps. pyocyanea*.

It would thus seem that the power to kill *Staph. aureus* may be considered as a suitable index of the value of alcohol in skin sterilization. It should be noted, however, that, owing to the alcohol-fast nature of the genus *Mycobacterium*, alcohol may be expected to be inefficient as a bactericidal fluid for *M. tuberculosis*. It is possible, though hardly probable, that failure in this respect led to an accident following which the use of alcohol for sterilizing syringes for the administration of parenteral injections was condemned by Bigger *et al.* (1940), though these workers also showed that alcohol failed to destroy streptococci in sputum used to contaminate syringes in certain of their experiments.

Recommendations by Previous Observers regarding Suitable Strength of Alcohol

Where contact may be prolonged weak mixtures are effective. Cruickshank *et al.* (1942) have shown that *Staph. aureus*, *Bact. coli*, and *Ps. pyocyanea* may be destroyed in from 0.5 to 24 hours by 25% alcohol. The length of time necessary to achieve sterility in certain of their experiments shows that 25% is obviously an ineffective strength for use in skin sterilization, where contact of the reagent with the skin is limited by the volatile nature of alcohol and by considerations of practical utility. These authors quote Minervini (1898), however, as having shown that the most germicidal concentration of alcohol is between 50% and 70%. Garrod and Keynes (1937) state that the optimum strength of alcohol is 70%. Bigger *et al.* (1940), while condemning the use of alcohol for sterilizing syringes as stated above, consider that a solution containing 70% alcohol has a much greater bactericidal action than the 95% spirit described as suitable by Lawrence (1940). The *British Medical Journal* (1940, **1**, 96) in a leading article quotes Regamey (1939) as finding that *Bact. coli* in broth culture was destroyed within 15 seconds by all concentrations of alcohol between 50% and 99%, and within one minute by 40%. *Silk threads* contaminated with *Bact. coli,* however, were sterilized in one minute only by concentrations of 50% and 60%; 70% took 3 minutes, 80% 15 minutes, while in 90% and 99% the organisms survived for 24 hours. Similar results were found with staphylococcus and streptococcus, except that the optimum concentration for staphylococcus was somewhat higher.

For use *on the skin* the following recommendations have been made from time to time:

95%: Hatfield and Lockwood (1943) found that the best results were obtained when 95% alcohol was used after *tincture of iodine,* but that consistently low counts were obtained after alcohol alone.

76% by weight: Colebrook (1941) reports the use of alcohol of this strength against streptococci on the skin—the streptococci were not completely eliminated.

70% by weight: Price (1939) is quoted by Colebrook as having shown that this is the most effective concentration of alcohol.

70% by volume: Has been recommended in certain official publications.

Various references to "70% spirit," "75% spirit," etc., may be found in the medical press and in commercial medical literature.

In the course of some unpublished work on skin disinfection (using *Staph. aureus* as an "indicator organism") carried out in 1941 by B. W. Lacey and myself, "industrial spirit" was used as a control in all experiments. This was very effective, but it was decided for the sake of completeness to carry out an *in vitro* test of the relative value of falling dilutions of alcohol. Method 1 of those given below was used, and results suggested that 65% was below the effective level for a period of exposure up to two minutes: 70% was not used.

Ether.—Ether is commonly applied to the skin as a part of the pre-operation toilet. It was found ineffective as a fluid for sterilizing syringes by Bigger *et al.* (1940), and its use as one of the reagents tested in the above-mentioned work by Lacey and myself suggested that its bactericidal effect when applied to the skin is inconsiderable.

Present Investigations

Purpose.—In view of the facts and considerations referred to above it was thought worth while to test yet again the *in vitro* effect of alcohol–water mixtures on *Staph. aureus* over a narrow time-range; to test the effect of such dilutions on the artificially contaminated skin; to compare the results obtained by different technical methods, and with different organisms; and to carry out a small series of parallel tests with ether. In all of the tests, unless otherwise stated, the dilutions used were made by mixing *measured volumes* of alcohol and water. They were thus slightly stronger than their nominal strength expressed as percentages by volume (see "Percentages of Alcohol" above).

Methods of Demonstrating Antibacterial Action Employed

1. *Glass Bead Method.*—Small unperforated glass beads as used in the "transfusion-giving set, hospital pattern," were placed in a thick suspension of organisms. They were then removed and dried. The dilutions of alcohol under test were poured on to sterile dishes, and a bead was placed in the mixture for a measured time; it was then transferred, with or without a preliminary washing in water, to sterile broth or to the surface of the agar in a Petri dish or covering one side of a 1-oz. screw-cap bottle. (When beads were transferred to the solid medium they were rolled freely about on the surface of the agar before incubation.) The media so inoculated were then incubated. A somewhat similar method—"Krönig and Paul's garnet method"—was employed by Hailer and Bockelberg (1939) in estimating the germicidal efficiency of the halogens on anthrax spores. In the course of the work it was found that washing of the alcohol-treated bead is necessary when it is to be used to inoculate a solid medium.

2. *Filter-paper Method.*—Small pieces of sterile filter-paper were immersed in a suspension of the organisms to be employed. After drying, these were placed in the spirit mixtures under test and after a noted interval transferred to bottles of broth, which were then incubated; or they were washed in water and placed on the surface of an agar plate, from which they were removed after a short time in the incubator, incubation of the plates being continued.

3. *Fluid Inoculum Method.*—A known volume of bacterial suspension was added to a known volume of the alcoholic mixtures under test. Drops of the resultant suspensions after shaking were then transferred, after an observed time of contact, to bottles of broth, which were subsequently plated and the plates incubated.

4. *Contaminated-finger Method.*—The fingers were contaminated by rubbing the tips over the surface of a plate culture. Individual fingers were then either (*a*) wiped with dry cotton-wool to spread the organisms further and remove excess, after which they were dipped for a moment in dilutions of alcohol; or (*b*) they were wiped with cotton-wool moistened with the alcohol dilutions. The fingers were then left until apparently dry, after which they were again wiped on fresh plates of a similar medium.

5. *Prevention of Growth on Inoculated Solid Media.*—Areas of plates of appropriate media were inoculated with the indicator organisms. When these areas were dry drops of the test dilutions of alcohol were delivered to the middle of each area with a Dreyer's pipette and the plates incubated when again dry. The use of blood-agar plates and *Str. pyogenes* as the test organism afforded an excellent "indicator" method, as the effective concentrations were made very obvious by the failure of haemolysis in the area of spread of the alcoholic drops. To exclude the possibility that failure of growth after the application of alcohol to an inoculated area might be due to destruction of the nutrient properties of the medium (Hayward and Miles, 1943; Cawston and Colebrook, 1943) rather than to death of the organisms, the following controls were incorporated in two of the experiments carried out on *Str. pyogenes* by this method.

Control A

The centres of the areas covered by the spread of the drops of various dilutions of alcohol used—from 100% to 40%—were reinoculated with the strain under test after the alcohol had dried. Growth occurred as a result of each such reinoculation.

Control B

Parts of the areas over which each alcoholic dilution had spread were cut out and placed, inoculated surface down, upon a fresh plate of blood agar. *Growth failed to occur* where contact was made between the fresh plate and the alcohol-treated part of the excised portion of medium. *Growth occurred* where the fresh plate was in contact with such an area of the cut-out piece as had not been covered by the alcohol.

Hence (*a*) the medium was not destroyed by such exposure to alcohol as the method entailed, (*b*) the organisms were killed by the alcohol in the strengths which led to failure of growth.

6. *Killing of a dried film of organisms on a slide by the application of drops of descending dilutions of alcohol;* as indicated by the failure of growth development when the treated slide is applied to the surface of a plate of medium and incubated.

Results

Method 1.—The results of four experiments using *Staph. pyogenes* showed that for periods of contact ranging from 5 seconds to 2 minutes 100% and 98% alcohol are highly ineffective and 95% is less bactericidal than mixtures containing more water. The effect of 50% alcohol is probably less than that of mixtures containing less water. The optimum range therefore would appear to be between 60% and 90%. Two experiments indicate that 60% and stronger mixtures of methyl alcohol are as effective as dilutions of ethyl alcohol in killing *Staph. pyogenes.* Single tests suggested that "industrial spirit" and methylated spirit (tinted violet) are effective against *Staph. pyogenes* in a range from full strength to 60% or weaker.

The results of these experiments do not confirm the failure to sterilize staphylococcus-contaminated beads by the use of 65% spirit found in the experiment carried out in 1941 and referred to above. The failure then observed may have been due to a technical error such as incorrect dilution of spirit or contamination during manipulation or to a fault inherent in the method, such as bubble formation or clumping of the organisms with fixation of the outer layer and lack of penetration to the middle of the clump. It is considered that bubble formation is a likely cause, since this would tend to become more frequent as surface tension rises with increasing dilutions of the alcohol. It was thought to be the cause of a completely irregular result when the method was tried with a watery disinfectant. Similar irregular results, though to a lesser degree, have occurred throughout the experiments here summarized. They rendered the method inaccurate, particularly in fluid media. It was therefore discontinued.

Method 2.—Two experiments were made using this method on *Staph. pyogenes*. The method was not found very satisfactory. The first experiment, in which the pieces of filter-paper were placed in broth alone, after 10 seconds' treatment in each case, produced only two sterile cultures—one after treatment with 95% alcohol, the other after 65% alcohol. With reference to the latter, however, it was realized at the time that, owing to a hitch, exposure had exceeded 10 seconds; the test with this dilution had been repeated, and in the second broth growth occurred. The second experiment indicated that absolute alcohol is inefficient, while 80% to 50% were all bactericidal in 30 seconds, as shown by sterile results of both fluid and plate culture. Culture after 10 seconds suggested that 80% was less effective than the weaker mixtures, of which 60% gave the best result.

Method 3.—Using *Staph. pyogenes* and *Str. pyogenes*, one experiment for each was carried out. In the case of the test on *Staph. pyogenes* there was no growth on subcultures from mixtures containing 95% to 47.5% of alcohol after one minute's contact. A heavy growth occurred on subculture of a mixture containing 30% of alcohol after a similar time, but this strength was bactericidal after 15 minutes' contact. *Str. pyogenes* subcultures from mixtures containing dilutions of alcohol from 95% to 38% showed no growth after 10, 30, and 60 seconds' contact.

In view of these findings it seemed desirable to make further observations on the artificially contaminated skin. Six such tests were made as shown under Method 4.

Method 4.—Four experiments using *Str. pyogenes* were carried out. Two of these were partially spoiled by contamination. The combined results, however, indicate that, though of considerable value, absolute alcohol, and probably 70% alcohol, are less effective than mixtures of intermediate strength, while 65% showed a definite comparative inefficiency. Two of these experiments were made with true volumetric percentage dilutions. Two similar series of tests, also using correct volumetric percentage mixtures, were made on fingers contaminated with *Staph. pyogenes*. 100% to 65% were apparently effective; 60% was not.

In view of the difference between the results obtained with Method 4 and those which followed the use of the first three methods it seemed desirable to compare these findings with the effects of similar strengths of alcohol on inoculated areas on a plate of solid medium—i.e., on a surface upon which, like the skin, a certain dilution effect due to absorbable water is liable to occur. (It should be mentioned that all this work was carried out in a tropical climate of high humidity. The skin was thus liable to be more moist than is normal in a temperate or cold climate.)

Method 5.—Three experiments on cultures of *Staph. pyogenes* (Oxford) were made. The third test was carried out in duplicate, and true percentage dilutions by volume were used. In all experiments the best result was observed with strengths above 80% (*including absolute alcohol*); deterioration in antibacterial effect was marked by the time a dilution of 65% was reached. Eight experiments were carried out on cultures of *Str. pyogenes*. In four experiments true volumetric dilutions were used. The results of these tests may be summarized as follows:

A complete failure of growth, though over a diminishing area, resulted when alcohol of strength varying from 100% to 70% was dropped on plates inoculated with *Str. pyogenes*. An almost equally good effect was generally produced by 65% alcohol: 50% alcohol and weaker mixtures were relatively ineffective. The following chance observation is of interest. In one experiment the streptococcal culture used as an inoculum became contaminated with an organism giving a lemon-yellow colony on agar. Colonies of this contaminant appeared in considerable numbers in areas inoculated for the test and, while in this test the use of both 60% and 50% alcohol prevented the development of streptococcal colonies, scanty lemon-yellow colonies appeared on the area treated with 60% alcohol and growth of the contaminant was abundant on that treated with 50% alcohol.

In general it would appear (though this was not apparent in experiments using Method 4) that streptococci are killed by somewhat weaker alcohol than is necessary to kill staphylococci under parallel test conditions. One experiment was carried out on a local strain of *Ps. pyocyanea*: 100% to 60% were effective, 50% was not.

Method 6.—The discrepancy between the effects of spirit dilutions on dried inocula on glass (Method 1) and on inocula on the skin or on solid culture media (Methods 4 and 5) is thus considerable. The similarity between the observations recorded of the effects produced on the skin and on inoculated plates is equally striking. A final series of experiments was made to determine the effect on dry contaminated glass slides of drops applied in the manner previously used for inoculated solid media. The test thus resembled that on media in that the exposure to the reagent was determined by the time taken for the spirit to evaporate (rather than any fixed time interval), but differed in that the reduction of the alcohol ratio by absorption of moisture is avoided. Two experiments with *Str. pyogenes* and one each with *Staph. pyogenes* and *Ps. pyocyanea* were made. The two tests on streptococcus showed an effective strength down to 50%, with a limited effect produced by 40%. The experiment with staphylococcus showed an effective strength down to 60%: 50% was only slightly less effective; 40% also produced a limited effect. The experiment with *Ps. pyocyanea* showed that 50% alcohol was effective; lower dilutions were not tested on this species.

The results therefore are more comparable with those found by Methods 1–3 than those following the use of Methods 4 and 5, *except that absolute alcohol appears to be effective when used as in Method 6*. This may be due to absorption of enough moisture from the damp air, contact with which is unavoidable in experiments carried out by this method, and hence absorption of moisture may not, in fact, be entirely eliminated.

Ether

In this series of tests Methods 3 (modified), 4, and 5 were used.

Ether Added to a Fluid Culture.—Single experiments on *Staph. pyogenes*, *Str. pyogenes*, and *Bact. typhosum* were made. Ether was added to broth cultures of staphylococci and *Bact. typhosum*: The cultures were shaken up with the ether, and one drop from a Dreyer's pipette was delivered on to a plate. The cultures were then left for approximately 5 minutes, re-mixed with ether by drawing up into the pipette and expelling again a few times, and again plated. Finally this was repeated after leaving the cultures for a further 15 minutes approximately. Control cultures before the addition of ether showed that both cultures produced a confluent growth on a plate, on the area where one drop from a Dreyer's pipette had spread. The results after treatment with ether were as follows:—*Staph. pyogenes:* First subculture after shaking with ether gave *confluent growth*. Subcultures after approximately 5 minutes gave an average of 14 colonies; there was no growth from the last subculture (approximately 20 minutes after first mixing with ether). There was no growth from *any* of the three subcultures of *Bact. typhosum*. A similar test with two local strains of *Str. pyogenes* showed no growth from subcultures carried out at once and after 5 minutes.

Method 4.—One experiment on *Staph. pyogenes* and one on *Str. pyogenes* were carried out. Ether was quite ineffective in destroying either staphylococcus or streptococcus on the skin.

Method 5.—The method was slightly modified by using increasing numbers of drops on a single spot on inoculated plates to observe if any poor result following single drops could be attributed to the very high rate of evaporation. Tests were made on cultures of *Staph. pyogenes*, *Str. pyogenes*, and *Bact. typhosum*, with the following results:—*Staphylococcus and streptococcus:* Drops of ether from 1 to 8 produced only a slight progressive thinning of growth in the area on which they fell. In an experiment on *Str. pyogenes* (Milne) accidental contamination again afforded interesting information. On this occasion a Gram-positive bacillus contained in the inoculum was absent from all areas where ether had fallen—though present on the surrounding inoculated area—in tests made with 1, 3, 6, and 8 drops of ether. *Bact. typhosum:* No growth of this organism occurred over areas covered by single or multiple drops of ether on an inoculated area on a plate.

Summary and Conclusions

Some 30 experiments, using six different methods, were carried out to test the effect of various dilutions of ethyl alcohol on bacteria, with special reference to the optimal dilution for use on the skin. Observations were mainly made on *Staph. pyogenes* (usually the Oxford strain) and *Str. pyogenes* (Milne strain and local strains), but two tests were performed using a strain of *Ps. pyocyanea*. Six experiments, employing three methods, were made to observe the effect of ether on bacteria.

The methods used are described, and the result of the employment of each is summarized.

The following conclusions were drawn:

1. *Effective Strength of Alcohol for Destruction of Bacteria after Short Exposure.*—(*a*) *On a dry surface*:—The effective range of strengths of alcohol for the killing of non-sporing bacteria is between 90% and 50%. 95% and above are partially ineffective, 100% being markedly so. The lower surface tension of stronger alcoholic mixtures suggests that the upper limits of this effective range may be preferable to the lower, though against this must be considered the more pronounced fixing effect of strong alcohol, which may cause the coagulation of an exudate and the consequent protection of living organisms within the coagulum so formed (Bigger *et al.*, 1940). (*b*) *On the skin*:—Since the normal skin is more or less moist the effective range of alcohol for use upon it is somewhat different. 100% is commonly effective—at least on moister skins and under tropical conditions of temperature and humidity; while under similar conditions 60% to 65% may show a certain loss of efficiency. The washing of the skin before the application of alcohol might be expected to exert a similar effect unless subsequent drying were thorough. Further, the value of a low surface tension may well be of importance in increasing spread and penetration, for skin sterilization. It is therefore considered that, as a general recommendation under all climatic conditions, *80% of alcohol by volume* is probably most suitable for skin sterilization, though this will not be more effective than any other non-persistent agent for dealing with deep-lying resident flora.

2. *Bactericidal Effect of Ether.*—Ether is quite ineffective as a sterilizing agent for the skin, since its effect is very slight on staphylococci and streptococci when applied to a surface—though it is effective against certain bacillary forms, both Gram-positive and Gram-negative.

My thanks are due to Brig. H. B. F. Dixon for permission to publish this paper, and to Sgt. G. R. Walters, R.A.M.C., and Pte. C. Abrahams, W.A.A.M.C., for assistance in carrying out the work.

The report for 1944 of the St. John Ophthalmic Hospital at Jerusalem has been issued from the Chancery of the Order, St. John's Gate, London, E.C. The hospital was founded in 1883, and during the year under review Field-Marshal Viscount Gort, High Commissioner of Palestine and Transjordan, paid a visit as a compliment to the work of the Order of St. John in Palestine. All the difficulties of perpetual changes of personnel have continued. So far as the decline in the number of patients is concerned, the Warden, Dr. Norman Manson, states that it is due to the impossibility of getting nurses and ward maids. This shortage is so acute in Palestine that several hospitals are almost closed. The improvement in the military situation has not been followed by any relief on the economic front; the cost of living is at least as high now as it was when Palestine was packed with troops. The clinical work has been carried out almost entirely by two surgeons and by two British Sisters with the support of a staff nurse seconded by the Director of Medical Services. The number of new cases seen during the year was 21,776, of whom 17,700 were Moslems, 3,270 Christians, and 806 Jews. The total number of patients suffering from acute conjunctivitis was 7,507, and 850 of these were complicated by corneal ulceration, which went on to perforation in 176.

ESTIMATION OF SERUM PROTEINS

BY

HANS HOCH, Ph.D.Vienna
Freedom Research Scholar

AND

JOHN MARRACK, D.S.O., M.C., M.D.
Professor of Chemical Pathology in London University

(From the Hale Clinical Laboratory, London Hospital)

During recent years interest has been focused on the concentration of proteins in serum, as it is possible that, besides the gross reduction that is found in cases of famine oedema, a less severe reduction of the average concentration of protein in serum may occur among a population whose protein intake is low. If such less severe reductions are to be detected, the methods of estimating serum proteins must be such as will give average results which do not deviate from the true values, or values as estimated by some standard method, by at most more than 2%. It appears that the copper sulphate method recently introduced by Phillips, van Slyke, *et al.* (1944, 1945) is accurate enough if proper precautions are taken and the correct formula is used in calculating the protein concentration from the observed specific gravity.

Chibnall, Rees, and Williams (1943) have pointed out that considerable laxity has crept into the technique of estimation of nitrogen by the Kjeldahl method; their main criticism was that the times allowed for digestion of the proteins were not sufficient to ensure the conversion of all the nitrogen to ammonia. Our attention in this matter was aroused when we tried the copper sulphate method of measuring specific gravity. The relation between the specific gravity found (S) and number of grammes in 100 ml. of serum (P) is expressed by Equation 1:

$$P = K (S - A),$$

where K and A are constants. Moore and van Slyke (1930) found that concentrations of protein in serum of patients suffering from nephritis could be calculated from the specific gravity found by weighing. The appropriate values for K and A in Equation 1 for such sera were 343 and 1.007. However, the results obtained by Moore and van Slyke with 9 sera from normal persons did not fit this equation. In the first report (1944) of the copper sulphate method the values of K and A appropriate for this method were again given as 343 and 1.007. It was stated by workers in this country that concentrations found by the method, using this formula, agreed with those deduced from nitrogen estimations by the Kjeldahl method. We, however, found that if A was taken as 1.007 the value of K, when the method was used in sera from women before and shortly after delivery, was in the neighbourhood of 380; and in the later edition of their report on this method Phillips *et al.* (1945) give the value as 377 for use with normal sera, and 360 for use with pathological sera. The apparent discrepancies between the results of Kjeldahl estimations led us to reconsider the method that we were using.

Prof. Chibnall kindly had the total nitrogen of 15 sera, on which we also were working, estimated in his laboratory, using the reagents as described in the paper quoted and digesting for 17 hours. On the average, the results obtained by the method which we were then using were approximately 2% too low. We have assumed that the nitrogen found by Prof. Chibnall's technique was 100% of the true value. Table I shows the results obtained on a series of sera with different amounts of compounds of selenium and different times of digestion; in all these we used 0.2 ml. of serum, 0.17 ml. of 30% solution of copper sulphate, and 1 ml. of sulphuric acid; after 10 minutes' digestion 1 g. of sodium sulphate was added. If selenium was used as catalyst 0.1 ml. of sodium selenate solution (0.85 g. per 100 ml.) or an equivalent amount of selenium dioxide was added after cooling. The results are given in Table I.

To test the method most commonly used in clinical laboratories, 10 sera were digested with sulphuric acid and copper sulphate, but only 0.3 to 0.5 g. of sodium sulphate, until straw yellow; 2 or 3 drops of hydrogen peroxide were then added and the mixture boiled for a further 3 minutes. This method returned 95.5% of the total. Even if the hydrogen peroxide was omitted the return was just under 95%.

As a routine we have digested with selenium dioxide for 3½ hours; in view of the above we can assume that the protein concentrations calculated from our Kjeldahl nitrogens are certainly not too high, and probably on the average are about 1% too low. If A in Equation 1 is assumed to be 1.007 the value of K that fits our results is 384—giving Equation 2:

TABLE I.—*Percentage of Nitrogen recovered in Kjeldahl Estimation (the amount obtained by 17 hours' digestion with selenate is taken as 100%)*

No. of Sera	Extra Catalyst Added	Time of Digestion	% Recovered
12	Selenium dioxide	3½ hrs.	99
21	Sodium selenate	50 mins.	99
17	Selenium dioxide	50 mins.	98·5
15	None	3½ hrs.	98
10	H_2O_2	3 mins.	95·5

$$P = 384\,(S - 1.007).$$

However, we found that the specific gravities of the drops formed in copper sulphate solutions by the method described by Phillips *et al.* are less than those obtained by weighing in a pyknometer; while, if the drops are formed in the copper sulphate solution instead of being allowed to fall into it from above, the resulting specific gravity is approximately the same as that found by weighing. It is possible that this change in specific gravity is due to air that is entrapped during the fall. The value 1.007 for A was chosen because this is the specific gravity of protein-free-ultrafiltrate from serum. If the difference in the specific gravities of drops formed inside and outside the copper sulphate solution is due to this entrapped air and not to a change in the serum protein it is reasonable to change the value of A and to retain a value of K which is appropriate for true specific gravities. We have found that Equation 3,

$$P = 366\,(S - 1.007),$$

fits our results obtained by weighing in a pyknometer. If this value of K is used the value of A obtained for normal sera is 1.0061. For convenience of calculation we propose Equation 4,

$$P = 364\,(S - 1.006).$$

The difference in the calculated results introduced by this change in K and A is negligible. A variety of equations, with different values of K and A, can be propounded that will fit the values of the apparent specific gravity as found in the copper sulphate method and of protein concentration found in normal sera, all containing between 6.5 and 7.8 g. of protein per 100 ml. To determine the two constants we need sera containing less or more protein. The obvious sera to use would be those of patients with nephritis and oedema. However, the figure given by Moore and van Slyke (1930) suggests that the constants suitable for such cases differ from those suitable for normal sera. As this method will probably be used to estimate proteins in sera of persons suffering from malnutrition, a form of the equation suitable for such sera will be appropriate. In the 6 sera with the lowest serum proteins obtained from returned prisoners of war we arrived at the results shown in Table II:

TABLE II.—*Protein Concentration in Sera of Returned Prisoners of War, calculated from the Specific Gravity by Equations 4 and 2 and from the Nitrogen, calculated by Kjeldahl's Method*

Case	Kjeldahl	Equation 4	Equation 2
3	6·14	6·08	6·03
15	5·27	5·17	5·07
11	5·97	5·93	5·88
18	5·51	5·39	5·30
5	5·88	6·01	5·95
16	6·02	6·19	6·14

In 4 out of the 6 the concentrations calculated by Equation 4 agree better with the Kjeldahl results than those calculated by Equation 2.

With 101 sera from "normals" (blood donors, laboratory technicians, and students), normal pregnant women, normal women after delivery, and returned prisoners of war, all of whom had lost much in body weight, we obtained the results shown in Table III.

TABLE III.—*Differences between Protein Concentration calculated from the Specific Gravity by Equation 4 and from Nitrogen Estimation*

Per cent.	Normals	Returned Prisoners of War	Ante-natal	Post-natal
+ 5·0 to + 5·9	0	0	0	1
+ 4·0 to + 4·9	1	0	0	2
+ 3·0 to + 3·9	0	2	1	6
+ 2·0 to + 2·9	0	5	1	4
+ 1·0 to + 1·9	3	2	4	3
− 0·9 to + 0·9	10	7	11	12
− 1·0 to − 1·9	4	2	5	2
− 2·0 to − 2·9	1	5	5	0
− 3·0 to − 3·9	1	1	4	1
− 4·0 to − 4·9	0	1	0	0
− 5·0 to − 5·9	0	0	1	0
Total number	20	25	32	31
Mean difference %	−0·2	−0·1	−1·0	+1·4
K calculated statistically ..	354	359	327	345
A „ „ ..	1·0054	1·0057	1·0037	1·0052
K calculated for A = 1·006 ..	365	364	368	359

It should be noted that Equation 4 is based primarily on the assumption with regard to the value of A. Statistical calculation of the equation that fitted the results would give lower values for A in Equation 1.

Phillips *et al.* (1945), in their second description of the method state that the equation suitable for pathological sera for A in Equation 1.

$$P = 360\,(S - 1.007):$$

We have, however, found that Equations 2 and 4 fit the pathological sera that we have examined. Phillips *et al.* also recommend that Equation 5 should be used generally for all sera. But this would result in a discrepancy of about 6% between estimations made by this method and those based on accurate estimations of the protein nitrogen.

Specific gravity methods have been criticized in the past because they have given results that disagreed with those derived from Kjeldahl estimations. It appears, however, that some of the Kjeldahl methods in use are liable to errors of at least 10%; the grosser discrepancies may be due to faults in the Kjeldahl methods used. The copper sulphate method is extremely simple and convenient. If a stock solution accurately made up or even a series of standard solutions were issued from a centre, gross discrepancies between the results of estimations of serum proteins would be avoided.

The drops should be allowed to fall into the fluid, as described by Phillips *et al.*; if formed in the fluid, a separate dropping pipette must be used for each drop and much of the convenience of the method is lost. In an established laboratory a gradient method as described by Jacobsen and Linderström-Lang (1940–1) may be quicker and more convenient; we propose to publish a paper on this method shortly. Both these methods have the advantage over other specific gravity methods that changes of temperature have little effect.

The specific gravity which we have considered is the ratio of the weight of a given volume of serum to the weight of an equal volume of water, both at 24° C. The difference in the specific gravity observed, if the measurement is made at a different temperature, is only about 0.00001 per degree, as the coefficient of expansion of serum differs little from those of the copper sulphate solutions. If, therefore, the specific gravity is measured at a temperature as low as 14° or as high as 34°, instead of 24°, the error in the calculated concentration of protein would amount to only about 0.04 g. per 100 ml.

As Phillips *et al.* point out, it is essential that, in preparing the standard solutions, the stock solution and water used for dilution should be at the same temperature. If this precaution is observed the specific gravities of a standard solution at 24° (that is, the ratio of the weight of a given volume of solution at 24° to that of the same volume of water also at 24°) will not vary by more than ±0.0001 if the dilution is done at any temperature between 10° and 40°. The stock solution should be prepared at 24°; but an error of not more than ±0.0001 in the specific gravities of the standards will be introduced if the solution is made up at any temperature between 14° and 34°. The volume of the drop of serum should be about 0.02 ml. The height from which it falls should be such that it forms a ring when it enters the fluid. If cups or umbrellas are formed the apparent specific gravities will be higher; if the pipette is not steady fluffy rings will be formed and the apparent specific gravity found will be less.

Summary

The copper sulphate method for measuring specific gravity of serum gives satisfactory and consistent estimates of the protein concentration.

The apparent specific gravities found by this method are less than the true specific gravity.

The equation recommended for calculating the protein concentration from the apparent specific gravity is $P = 364 (S - 1.006)$.

For satisfactory and consistent measurements of serum protein by the Kjeldahl method, selenium dioxide should be used as a catalyst and digestion should be continued for at least one hour, and preferably for 3½ hours.

We wish to express our thanks to Prof. Chibnall for his advice and assistance.

FOUR CASES OF TYPHUS FEVER IN GREAT BRITAIN

BY

H. L. WHITCHURCH BEACH, M.B., B.S., D.P.H.

Medical Superintendent, City Hospital, Bradford

AND

JOHN K. RENNIE, *M.C.*, M.D., F.R.F.P.S.

Physician, E.M.S.

Typhus fever is rare in Great Britain. From a review of the recent literature on its incidence it would appear that only one case occurring in 1944 has been recorded (Agnew and Kyles, 1944). As several cases of typhus fever are now under treatment in this country, it may prove of interest to report a small series of four patients who developed this disease while in hospital in Bradford. Three of these cases had been under constant medical supervision before the development of the disease, and it has thus been possible to follow the course of their illness from the day of onset.

The four patients referred to in the following report had been released from the same prisoner-of-war camp in Germany, in which, so far as can be ascertained, typhus fever was endemic. They were all disinfested by the routine procedure of insufflation of their clothing by dichlor-diphenyltrichlorethane (D.D.T.) powder on April 26, 1945. They arrived in England two days later and were immediately transferred to hospital, where on admission they were found to be free from lice.

Case I

A man aged 25. His general condition on admission was fairly satisfactory, his weight then being about 14 lb. below his normal. On May 3—i.e., seven days after disinfestation—there was an unexplained rise of temperature to 102° F., with a pulse rate of 124. Prodromal symptoms were entirely absent, apart from a feeling of "fatigue," which persisted throughout the illness. The pyrexia and tachycardia continued for 10 days and then fell by slow lysis over a period of four days. The total duration of the febrile period was 13 days, and while during this time the patient developed a fairly well marked degree of toxaemia, this at no time gave rise to any anxiety. His mental condition remained fairly normal throughout the illness, and although towards the end of the first and beginning of the second week there was definite mental confusion, there was neither violent delirium nor restlessness. Conjunctival suffusion was present at the start of his illness. The rash, which was reported to be macular in character, developed on the fourth day and showed the typical distribution over the trunk and limbs only. When seen by one of us eight days later it had entirely disappeared. There was no splenomegaly. On the 14th day of the disease there was clinical evidence of meningism, but lumbar puncture revealed a normal cerebrospinal fluid. The following pathological investigations were made:

5th day of disease:
  Widal reaction = Positive agglutination to 1 : 50 against *B. typhosus*
12th day of disease:
  Weil-Felix reaction: agglutination against OX 19 to 1 : 250
14th day of disease:
  Weil-Felix reaction: agglutination against OX 19 to 1 : 1000

The patient made an uninterrupted recovery.

Case II

A man aged 44. The general condition of this patient remained satisfactory until May 5—i.e., 9 days after disinfestation—when there was a rise in his temperature and pulse rate to 99° F. and 100 respectively. The next day his temperature had risen to 104° F. At this time the patient had a septic right thumb, which required incision and drainage. From this, the 4th day of his illness, his general condition deteriorated steadily, so that by the 10th day the typhoid state was well established. There was a low muttering delirium, and signs of cardiovascular failure soon became apparent. When seen by one of us on the 12th day he was *in extremis*, and died within 24 hours. On the 6th day a subcuticular mottling appeared over the trunk, together with a petechial rash, which was profuse on both trunk and limbs. On the 10th day the spleen was reported to be slightly enlarged. Conjunctival injection was marked.

Pathological reports included the following relevant findings:—On the 11th day of disease: White blood count, 16,000 per c.mm.—polymorphs, 64%; lymphocytes, 28%; Türck cells, 2%; mononuclear leucocytes, 6%; blood urea, 86 mg. per 100 c.cm. Urine: Albumin ++; a few granular and epithelial casts present. Weil-Felix reaction: Agglutination against OX 19 to 1: 10,000; against OX 2 to 1: 50.

At the necropsy all the organs showed evidence of passive congestion. The spleen was normal in size, with soft diffluent pulp. There was a diffuse rash over the body, merging with post-mortem lividity. Discrete small macules were present on the trunk, and were profuse on the legs and inner aspects of the arms. A few petechial haemorrhages were also present.

Report on the skin section: In the skin macule the small vessels showed marked congestion, with collections of inflammatory cells (mainly lymphocytes) in and around the adventitia.

Case III

A man aged 25. This patient was discharged home on leave four days after his arrival in England and was readmitted to hospital 12 days later. He stated that for the preceding six days he had been suffering from vomiting and diarrhoea with severe headache and backache, the illness beginning with a shivering attack. The illness commenced 11 days after disinfestation, assuming that the onset dated from this shivering attack. On admission his temperature was 100.6° F. and pulse rate 94. The pyrexia which followed was of an irregular character and reached 104.8° F. on the 9th day of the illness, and there was a tachycardia of 150 on the 11th day. The febrile period continued for 13 days and then fell by slow lysis over 4 days. The rash appeared on the 9th day, and consisted of petechiae, mainly present on the abdomen and legs, but this distribution soon involved the whole trunk and limbs. At this time there was a very well marked conjunctival suffusion. An enlarged spleen was easily palpated and was found to extend two fingerbreadths below the left costal margin. During his illness there was a mild toxaemia, accompanied by lethargy and a fine tremor of hands and feet. There was also some mental confusion, most marked at night, but no undue restlessness.

The pathological findings were:—On the 9th day of disease: Blood urea, 90 mg. per 100 c.cm. Urine: Hyaline and occasional granular casts present. Weil-Felix reaction: Agglutination against OX 19 to 1: 250. On the 16th day of disease the Weil-Felix reaction showed agglutination against OX 19 to 1: 1000. The patient had a rapid convalescence.

Case IV

A man aged 29. He was a contact of Case I, being a patient on the opposite side of the ward, but as he was ambulant during the early part of the latter's illness a closer contact may have occurred. On the 27th day after disinfestation the patient complained of nausea, fairly severe frontal and occipital headache, and malaise. His temperature and pulse rate in 12 hours rose from normal to 103.2° F. and 96. This rise was followed by a short febrile period of only 5 days, when the temperature was of an irregular character, as in the other three cases. Apart from a mild conjunctival injection, there were no other clinical signs during this man's illness.

Pathological Report.—2nd day of disease: Weil-Felix reaction—positive agglutination against OX 19 to 1: 50 and against OX K to 1: 25; 6th day of disease: Positive against OX 19 to 1: 1000. The patient's general condition remained excellent throughout, and his symptoms rapidly disappeared when his temperature had subsided.

Commentary

Case II suffered from a severe attack of typhus fever, the diagnosis of which appears obvious in retrospect but was rendered difficult at the time by the presence of the septic thumb, which dominated the clinical picture. The continued pyrexia was originally attributed to a septicaemia secondary to the septic focus together with a possible concomitant attack of malaria. That death occurred in this man, who was 44 years of age, confirms the recognized fact that the mortality rate from typhus fever increases with the age of the patient (Mackenzie, 1941).

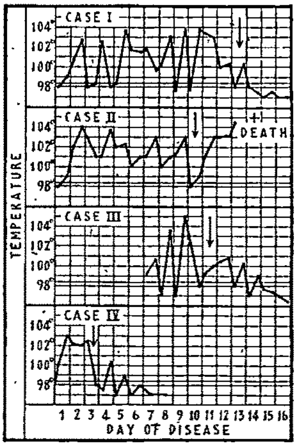
Cases I and III had fairly mild but typical attacks of typhus fever, although at no period of their illness was the toxaemia profound. These cases also differ from the classical description of typhus fever in that delirium was not pronounced and certainly was not of the dissociation or occupational type.

Case IV presents several interesting features: (*a*) The first sign of the disease developed 27 days after thorough disinfestation—i.e., 4 days longer than the recognized limit of the incubation period for this disease (Memo. on Louse-borne Typhus Fever, No. 252, 1941). As already stated, this patient was a fairly close contact of Case I throughout his illness. That Case IV was a secondary infection from Case I is the obvious explanation, but no other secondary cases have occurred either among other patients in the same ward or among the nursing or medical staff. There have been no secondary cases from Cases II and III, which were nursed in different wards from Case I. (*b*) The attack of typhus fever was of the abortive type, in that the total duration of the illness was only 5 days and in that the classical signs of the disease did not develop as in the other cases. Positive Weil-Felix reactions also occur in undulant fever in titres of 1 in 50 to 1 in 240, but the progressive rise in titre does not (Findlay, 1941). The Weil-Felix reaction in this patient showed a diagnostic rise in titre from 1 in 50 on the 2nd day of the illness to 1 in 1,000 four days later. (*c*) The early appearance of the positive Weil-Felix reaction on the 2nd day of the illness is uncommon (Felix, 1941). The patient was questioned as to the possibility of previous immunization against typhus fever. The last prophylactic injections he received were in July, 1942, but he is ignorant of their character, and it is impossible to determine this most important point. In the light of this case it is clearly of diagnostic importance to perform a serological examination at the earliest opportunity in any patient suspected of typhus fever. It is recognized that a titre of 1 in 80 to 1 in 100 is necessary before a clinical diagnosis can be confirmed.

Rash.—The typical exanthem occurred in three of these patients and appeared on the 4th, 6th, and 9th days of their illness. It showed the typical distribution of that of typhus fever in that, while absent on the face, it was profuse on the body and limbs, particularly in Cases II and III. The rash was definitely petechial in character, the size of each petechia varying between 1 and 2 mm. in diameter. The colour, originally a bright pink, changed to a dark bluish-red. It did not appear in crops, and persisted distinctly for 3 days in Case III before fading, when it was replaced by a brownish staining which gradually disappeared. The subcuticular mottling described in this disease was widespread on the trunk and limbs in Cases II and III, but this element of the rash faded more quickly than did the petechiae in Case III. Accompanying the rash there was conjunctival suffusion, which was well marked in the first three cases.

Type of Pyrexia.—As can be seen from reference to the accompanying temperature charts, the type of pyrexia is similar in all four cases. The temperature shows a well-marked intermittent and remittent character—a feature which is even more pronounced in the four-hourly charts. Disproportionate bradycardia, as is said to occur in some cases of typhus fever, was not observed in this small series of cases.

Penicillin Therapy.—Penicillin was administered to these patients for prophylaxis against the possible development of the secondary infections which are likely to occur during the course of this disease. Such conditions as bronchopneumonia, septic parotitis, and septic conditions of the skin have been common in the epidemics of typhus fever in Europe (Megaw, 1942). Penicillin was given by three-hourly intramuscular injections of 15,000 units to all four patients, but, as can be seen from the temperature charts, it was begun at different stages in these cases. In Case I penicillin therapy was started on the 13th day of the disease, when the temperature and pulse rate were already falling by lysis. In Case II the first dose of penicillin was given about 72 hours before death, when the patient was profoundly toxaemic. Case III received the first injection of penicillin on the 11th day of illness, and in Case IV it was first given on the 2nd day. No attempt is made in such a small series of cases to draw any conclusions on the effect of penicillin on this disease.



Temperature charts of the four cases of typhus fever. The arrows indicate the beginning of penicillin therapy.

Summary

Four cases of typhus fever imported into England by repatriated prisoners of war are described and the important clinical features of each case are briefly reviewed. One patient died, and a note on the post-mortem examination is included. Another of these patients had an abortive attack, the interesting features of which are described in some detail.

We wish to thank Drs. Weiner and Yang for the use of their clinical notes, and Drs. Kellett and Gartside for the various pathological examinations and reports.

SORE FINGER-TIPS IN INDUSTRY

PROTECTION BY HYDROGEN PEROXIDE

BY

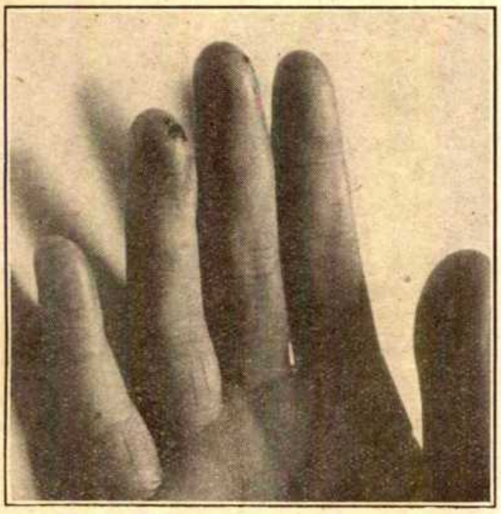
J. VINCENT BATES, M.B., B.Ch.

Part-time Works Medical Officer, Aylesford Paper Mills, Larkfield, Maidstone

This is a record of an accidental discovery of a promising method for preventing injury to the skin of the finger-tips by constant friction against a rough surface.

Medway Paper Sacks Ltd., an associated company of Albert E. Reed and Co., paper makers, Aylesford, Kent, is engaged in making large sacks from strong brown paper (kraft). This paper has a rough surface, and the sacks are finished by passing either one end or both ends through a wire-stitching machine. The paper passes through this machine with a rapid jerky motion, and is guided by the operator's fingers. During the whole of an eight-hour day her fingers are rubbing over the rough dry surface of the paper. This amount of friction causes damage to the skin of the finger-tips, and until recently two-thirds of the women working on the stitching machines visited the surgery about once a fortnight for treatment. The remaining one-third were unaffected, although many of them had been on the same work for years. The reason for this has not been discovered; there is no difference in the method of handling the paper.

Treatment consisted in applying half-inch zinc oxide plaster so as to cover the finger-tip completely. This relieved the pain, and enabled the work to be continued. The adhesive plaster was kept on day and night, and was renewed every few days until the finger had healed. There is no evidence to show that this treatment slowed up production, but time was wasted in surgery attendances, and a good deal of discomfort was suffered. The lesion produced by so much friction on the finger-tips is shown in the photograph reproduced here.



Photograph of the right hand of Mrs. N. G.

The striking feature about the affected finger-tips was the absence of the horny layer of the skin. This is not well shown in the photograph, but the drops of blood exuding from the tips of the middle and ring fingers can be clearly seen. These two fingers were the ones usually most severely affected. The thumb nearly always escaped. There was often a general hypertrophy of the skin of the finger-tips, producing a bulbous appearance, which is seen in the photograph on the ring and little fingers.

Various measures had been tried to prevent this trouble. Industrial rubber gloves were useless, as the worker lost her sense of touch. Thick rubber finger-stalls were unsatisfactory for the same reason, and output was slowed up. Thin rubber finger-stalls wore out in a few hours. Trials were made of a hard-setting rubber solution painted on the finger-tips before starting work. This was satisfactory, but was discarded because the solution had to be reapplied every two or three hours.

Method

At this stage one of the workers volunteered the information that three weeks previously she had accidentally splashed a finger with 20-vol. hydrogen peroxide while dressing her child's hand. She noticed during the next few days on the machine that this finger-tip did not get sore like the others. She therefore tried applying peroxide to all her finger-tips. For the first week she did this at night and during the dinner hour. Her fingers were so much better that during the second week she applied the peroxide at night only. The number of applications was still further reduced to three or four during the third week. To her surprise she had had no sore finger-tips since using peroxide. For four years she had been working on stitching machines, and had often attended the surgery for treatment.

It was clear that this remedy was worth investigating. Six of the worst sufferers volunteered for a trial, and the result was so promising that arrangements were made to issue peroxide to all the workers (21 in number) who had been troubled with sore finger-tips. These 21 women were given 1-oz. wide-neck bottles three parts filled with 20-vol. hydrogen peroxide. These bottles had a bakelite screw cap and were labelled with the worker's name and clock number, and the date of issue. The women kept them in their handbags. Instructions were given to dip each finger-tip into the peroxide and to wave the hands in the air till the liquid dried. This was to be done three times a day—at night, on starting work in the morning, and during the dinner hour. Within a few weeks it was quite clear that this routine was producing a notable improvement in the fingers of all the women. By subsequent inspection it was found that in many cases the fingers could be fully protected by reducing the number of applications to three or four weekly.

The effect of the treatment is indicated in the table below, which compares over two periods of six months the surgery attendances of 12 of the 21 women who had been working under identical conditions both before and after treatment. No comparison has been made in the attendances of the remainder, whose work during the two periods is not exactly comparable. They had been doing other work at intervals, had been working with different sorts of paper, or had left during the period of the test.

Table showing Surgery Attendances for 12 Workers for the Treatment of Sore Finger-tips

Commentary

It is realized that this is by no means an ideal control, but an adequate control series would have required some interruption of the treatment after it had been begun, and the benefit to the workers was so clear that this course seemed unjustified. There is, however, no reason to suggest that the two periods are not comparable: the output per worker was approximately the same, the amount of absenteeism from all causes in the group was actually greater in the six months prior to the introduction of the peroxide (233 as against 147 days lost), and "surgery attendance" indicates a lesion of about equivalent severity in each period. The women themselves are in no doubt that the treatment has been beneficial, and it has been simple to administer. Their bottles of peroxide require filling every four to six weeks, and they come regularly to the surgery for this purpose.

In order to determine the deterioration in the strength of the peroxide after five weeks' use, analyses were carried out in the chemical laboratory of Albert E. Reed and Co. The stock bottle of 20-vol. H_2O_2 was found to contain 20.4 volumes of hydrogen peroxide. Samples were taken from the 1-oz. bottles of six workers at random after they had been in use about five weeks. These samples were analysed, and they showed practically no deterioration. The weakest was 19.5-vol. H_2O_2. This test was done in hot weather, and of course the stoppers of the bottles were frequently removed by the users.

Efforts have been made to find out exactly why peroxide should prevent sore finger-tips, but without success. Peroxide in this strength produces some coagulation the surface proteins in the skin, which appears usually as a number of small white pin-points. There is no reason to assume that there is any particular chemical substance in the paper against which peroxide is giving protection, and its action is presumably due to the effect of coagulation on increasing the resistance of the skin to friction. No ill effects have been caused by the use of 20-vol. hydrogen peroxide in the way described above.

Summary

An accidental observation by a wire-stitching machine operator in a paper-bag factory has led to the discovery of a method which largely protects the skin of the finger-tips from damage by the constant friction in this work. The operator is supplied with a small quantity of 20-vol. hydrogen peroxide, into which each finger is dipped. The necessary number of applications varies from three times a week to four times a day. All the workers have noted the considerable protection which this treatment affords. In a group of 12 women working under strictly comparable conditions for a

period of six months before and after treatment, the number of attendances at the surgery for the treatment of sore and bleeding finger-tips fell from 192 to 21. The result of this small series would appear to make further trials on a larger scale worth while.

My thanks are due to the management and staff of the Aylesford Paper Mills and Medway Paper Sacks Ltd. for their help in carrying out this investigation, and for their permission to publish this paper

A THERAPEUTIC TRIAL OF CHOLINE CHLORIDE IN INFECTIVE HEPATITIS

BY

J. S. RICHARDSON, M.V.O., M.D., M.R.C.P.

Lieut.-Col., R.A.M.C.

AND

W. S. SUFFERN, M.B.

Capt., R.A.M.C.

Choline is a powerful lipotropic agent (Best and Huntsman, 1932), and in experimental animals has been shown to have the effect of reducing the cirrhosis which follows the infiltration of the liver with fat after taking a high-fat diet (Daft, Sebrell, and Lillie, 1942; György and Goldblatt, 1942). It is considered to exert its lipotropic effect by promotion of lecithin (phospholipid) synthesis in the liver, as phospholipids are actively concerned with the transport of fat and cell structure.

The action of choline in preventing cirrhosis is different when methods other than dietetic are used for the production of fatty livers (McHenry and Patterson, 1944). It has no effect in preventing the accumulation of cholesterol esters in "cholesterol" fatty livers, and while in curative experiments it causes a rapid decrease in glycerides, the reduction of cholesterol esters is slow. The fatty liver produced by the ketogenic fraction of the anterior pituitary is not prevented by choline, and large doses are required to prevent damage in carbon tetrachloride poisoning or to increase the disappearance of fat from the liver in the recovery period of phosphorus poisoning.

Himsworth and Glynn (1944) have distinguished two distinct types of liver injury due to diet. One follows long-continued fatty infiltration of the liver due either to excessive intake of fat or to deficiency of lipotropic factors such as choline, and the second results from lack of amino-acids in sufficient amounts in the diet. The injury resulting from the amino-acid deficiency is characterized by necrosis, and against this choline has no beneficial effect—in fact, Himsworth and Glynn suggest that it tends to aggravate the hepatic necrosis by reducing the high fat content of the liver. It will be seen, therefore, that though choline prevents fatty infiltration and the consequent cirrhosis that results from the intake of an excessive amount of fat, there are various experimental conditions in which it is unlikely to have a beneficial effect on the liver.

The work that is recorded here was started at about the same time as Higgins and his associates began their investigations into the therapeutic effect of methionine in infective hepatitis at Oxford (Higgins *et al.*, 1945). There was, however, a distinct difference in the circumstances under which the trials were undertaken, as 21 of our cases were patients in a general hospital over-seas, and thus it was not possible to carry out the detailed biochemical study to which reference is made in their paper.

The Trial

No attempt was made to select cases so as to get those of comparable severity, but alternate patients were given choline chloride 1.5 g. a day for the first eight days following admission. All the patients were serving soldiers between 20 and 50 years of age, and their diets were similar except for the plentiful supply of fresh fruit for drinks that was available for those treated in Algeria. Both the treated and the control series received vitamins A and D (and K in 21 cases) as an addition to a low-fat high-carbohydrate diet. The amount of protein in the diet was left largely to the patient's preference, and under the conditions of the experiment it was not possible to determine the quantities each patient consumed.

Considerable care was taken to exclude liver disease fro other cause and the presence of any intercurrent infection— very important precaution in a hot climate. Special attentio was paid to the possibility of men having received an organi arsenical for any reason, and no case in which there was an doubt was included. The patients were treated in bed. Th decision as to when they should get up was recorded, as well a the length of stay in hospital, as a substantial reduction in eithe would be a very practical way of demonstrating therapeuti efficiency. The day on which their appetite returned was note for a similar reason, but the date of disappearance of jaundic was not, as discoloration of the conjunctivae persisted in severa cases after the patient was considered fit to leave hospital. Th only biochemical investigations that were undertaken wer repeated estimations of the serum bilirubin and examination o the urine for the presence of bile pigments.

Results

The level of the serum bilirubin was estimated on admissio This, coupled with the number of cases that had a rising seru bilirubin while under observation, was used as a means of asses ing the comparability of the treated and control series. Th number of days of malaise and the length of icteric perio before admission are shown for a similar reason in Table I.

TABLE I

	Subjects	
	Treated 16	Control 16
Duration of illness before admission, in days ..	8·3 (3–29)	8·1 (2–21)
Icteric period before admission, in days ..	1·4 (1–5)	1·7 (1–7)
Serum bilirubin on admission (mg./100 c.cm.)	4·7 (1·0–12·2)	6·1 (1·25–14)
Number of cases with rising serum bilirubin ..	5	6

The average number of days and the levels of serum bilirubin in milligramme re shown—the variations are in brackets.

In such a small series, when much larger numbers would b required to be statistically significant, the importance of findin means of showing that the cases were of comparable severity i obvious. It is thought that Table I shows this to be so, althoug it will be noted that the level of the serum bilirubin on admissio was lower in the treated than in the control cases.

The results of giving choline chloride can be seen in Table I and it may be mentioned here that they were closely similar i cases treated at home and those treated over-seas.

TABLE II

	Subjects	
	Treated 16	Control 16
Maximum serum bilirubin (mg./100 c.cm.) ..	6·0 (1·5–15)	7·9 (2·0–14·
First day of fall of bilirubin to 0·6 mg./100 c.cm.	25·1 (11–50)	30·1 (10–55)
First day urine bile-free	20 (10–29)	22·2 (10–42)
First day of return of appetite	15 (2–33)	14·4 (0–33)
First day allowed up	30 (13–54)	28·8 (13–46)
Duration of stay in hospital	35 (13–79)	40·7 (27–56)
Number of relapses known	4	5

Discussion

We were fortunate in getting our cases early on, in the perio of the disease that was accompanied by jaundice. The averag number of days that the urine was dark before admission t hospital was 1.4 in our cases, compared with 4.4 in the methionine-treated cases reported by Wilson, Pollock, and Harri (1945). The dose of choline chloride that we gave—1.5 g. dail —is approximately one-third of that of methionine used by th Oxford and Cambridge workers. This gives comparable dosag as regards methyl equivalents, and is probably adequate.

The figures shown in Table II for the first day on which th serum bilirubin fell to 0.6 mg. per 100 c.cm. and for the duration of stay in hospital are a little lower for the treated tha for the untreated cases. It is thought, however, that thes results, as a whole, must be taken to show that choline chloride under the conditions of the experiment, had no therapeuti value.

Summary

Alternate cases of infective hepatitis were given 1.5 g. of cholin chloride as a supplement to a low-fat high-carbohydrate diet wit the addition of vitamins. Sixteen cases were so treated, and n significant benefit over 16 control cases was noted.

Our thanks are due to Prof. L. J. Witts for suggesting the work and sending us the choline chloride, and for his generous advice and help. We also wish to thank Col. W. H. O'Riordan, *M.C.*, for permission to forward this paper for publication.

Medical Memoranda

Palindromic Rheumatism

This syndrome was described by Hench and Rosenberg (1941) on the basis of their findings in 34 cases; of these 19 were males and 15 females. They recorded multiple afebrile attacks of acute arthritis, peri-arthritis, and sometimes also para-arthritis with pain, swelling, redness, and disability. The attacks appeared suddenly, developed rapidly, and lasted for a few hours up to about 24, and recurred at short or long irregularly spaced intervals. The blood sedimentation rate was normal between attacks, but rose to an average of 24 on the uncorrected Westergren scale. The history in these patients extended over periods varying from 1 to 25 years, with from [illegible] up to 250 attacks a year. The attacks lasted from 3 hours to 6 days, and successive attacks affected different joints. The authors recognized the similarity to the angio-neural arthrosis described by Solis-Cohen (1911, 1913, 1914) and to the allergic arthritis described by Kahlmeter (1939), but the syndromes reported by the latter authors show certain fundamental differences from that of Hench and Rosenberg. Intermittent hydrarthrosis, excellently described by Garrod (1907), also differs from palindromic rheumatism in that the attacks generally recur in the same joint and at mathematically regular intervals. Cain (1944) recorded a single case apparently conforming exactly to the picture of palindromic rheumatism. No other case reports appear to have been published.

The following case seems to conform to the typical description:

A Port official was admitted to the Seamen's Hospital on Sept. 1, 1943. He gave a history of flitting pains in the joints, first noticed in 1930 after he had fallen into the river. The joints became painful and repeatedly swollen, and the disability lasted from 1 to 2 days at the most. There was great variability in both the type and the situation of the pain and also in its duration, but almost every joint in the body had at one time or another been affected. He had no constant symptoms except excessive perspiration. On examination tachycardia was present, but there was no other evidence of systemic disease. Temperature was normal throughout his stay in hospital. On the second day after admission he had swelling of the right knee-joint with erythema and tenderness. On the following day the left ankle-joint was affected. At subsequent periods during a six-weeks stay in hospital almost every joint in the body was involved. Blood sedimentation tests gave the following readings at approximately weekly intervals: 75/200, 43/200, 47/200, 51/200, 82/200, 10/200, and 23/200. A careful search revealed no focal sepsis. Radiographs of the chest were within normal limits. Electrocardiograms and the urine were normal. The Wassermann reaction, Kahn test, and gonococcal C.F.T. were negative. The white blood count was 9,000 per c.mm. (polymorphs 52%, eosinophils 1%, large mononuclears 3%, large lymphocytes 2%, small lymphocytes 42%). The blood serum did not agglutinate *Brucella abortus*. *X*-ray examination of bones and joints showed no pathological changes.

Various lines of treatment were tried, including a prolonged course of sulphathiazole, intramuscular injections of contramine, and the salicylates. The condition showed no improvement, and during the months which succeeded his stay in hospital the attacks continued almost exactly as before.

This complete therapeutic failure conforms to the experience of the authors quoted, and when the patient was last seen in Jan., 1945, his condition was virtually unchanged.

ALEC WINGFIELD, M.D., M.R.C.P.,
Physician with Charge of Out-patients, Seamen's Hospital, Greenwich.

Reviews

NEUROLOGY, PSYCHIATRY, ENDOCRINOLOGY

The 1944 Year Book of Neurology, Psychiatry and Endocrinology. Neurology, edited by Hans H. Reese, M.D. Psychiatry, edited by Nolan D. C. Lewis, M.D. Endocrinology, edited by Elmer L. Sevringhaus, M.D. (Pp. 712; illustrated. 18s. 6d.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co. 1945.

The mass of medical literature continually poured out makes the busy practitioner more and more dependent on critical summaries and reviews such as are provided by the *Year Book of Neurology, Psychiatry and Endocrinology*. The current volume maintains the standard of its predecessors. Choosing articles almost at random, we note that Dr. Denny-Brown has concluded that epilepsy is an infrequent complication of injury to the head in general, and that laceration of the brain is an essential factor, particularly if resulting in a cerebro-dural scar. Early convulsions within the first eight weeks must be distinguished from true epilepsy, which is of later onset. The electro-encephalogram naturally receives attention from various writers. Now that so much interest is taken in the scientific study of delinquency it is important to observe that the E.E.G. has not proved of value in diagnosing the criminal mentality. It is of course abnormal when the criminal has an organic disease of the brain, but the psychopath shows the same departure from normal, whether a criminal or not, while the non-psychopathic offender shows a normal rhythm. Post-mortem records bring to light a much larger number of abnormalities of endocrine glands and of new growths in paranoid than in non-paranoid psychotics. Dr. Nolan Lewis is very cautious in his assessment of the value of shock therapy. He agrees with the general experience that insulin is preferable for schizophrenics and electric shock for the manic-depressives. Psychoneurotics show questionable benefit. There is no good evidence that damage is done to the brain, and fractures and dislocations are not frequent enough to interdict the treatment in carefully selected cases. It now seems to be established that the muscular weakness of myasthenia gravis is due to a failure in the synthesis of acetylcholine. The serum of a myasthenic patient can inhibit this synthesis *in vitro* and can produce the curare phenomenon in the isolated muscle–nerve preparation from a frog. The action of thiouracil is the subject of several papers. If rats are injected with radio-active iodine the drug can be traced to the gland and the consequent inhibition by thiouracil of its synthesis into di-iodotyrosine and thyroxine observed. The production of thyroid hormone stops promptly and almost completely when thiouracil is given. Clinically it brings down the basal metabolic rate, though this response is delayed when iodine has been previously administered. These few examples will give some idea of the varied interest of the *Year Book* for 1944.

AMERICAN MEDICAL PRACTICE

American Medical Practice in the Perspectives of a Century. By Bernhard J. Stern, Ph.D. (Pp. 156. 8s. 6d.) New York: The Commonwealth Fund; London: Oxford Medical Press.

This is a preliminary statement made by a committee of the Council of the New York Academy of Medicine, instructed to review the nature, quality, and direction of the economic and social changes taking place and to be anticipated in the U.S.A., and to report what the medical profession can do about it. It included doctors, dentists, nurses, and laymen. The book is well documented and contains a valuable series of monographs designed, presumably, to serve as a basis for a later report and recommendations. The problems dealt with have a strong resemblance to those which face the medical profession everywhere. The development of medical practice in the U.S.A. and the gradual rise of the doctor in the public estimation are well told. The question of "specialism" receives much attention because it is largely responsible for the rise in the cost of medical care, and has influenced the distribution of the profession. Its growth is traced largely to the introduction of expensive diagnostic instruments needing special competence to handle. There are no fewer than 14 certifying boards for "specialism" in the United States, and in 1942 there were 49 "specialists" to every 51 general practitioners. As they require elaborate hospital facilities they are found mainly in the large and more wealthy centres of population. "Specialism has complicated medical care in manifold ways and increased the cost tremendously." But it has had a stimulating effect on the work of the general practitioner, whose standard of efficiency is steadily rising.

The gradual decline of the family doctor is noted with regret because "the standards of general practice determine the quality of medical care which the rural and lower income groups receive." A survey in New York shows that two-thirds of the lower income group had no family doctor. There is a tendency to more and more "office" consultations in buildings in which the doctors can share the "overheads," but this is making the doctor more remote from his patients. Much attention is given to the problem of distribution of the profession. In the poorer areas where the population is increasing through high birth rates little inducement is offered for building up a practice; the young men are therefore attracted more and more to the wealthy areas. The greatly increased cost of medical education is a significant factor in deciding the distribution of doctors. It is estimated that it costs a minimum of 5,000 dollars to cover the student's career, and then there is the steadily mounting cost of his equipment. Great stress is laid on the fact that where the sickness and death rates are high the proportion of doctors is low. The lower income groups need more medical care than the others, but they spend less on it and get less, even taking into account charitable services. The death rate of the population is also shown to be related to the means of its various groups. The most striking instance of this is to be found in the negro population, where the death rate for males is 75% higher than for the whites, and for females 74% higher. The negro has a lower expectation of life now than the whites had 40 years ago.

In the next instalment of this interesting inquiry the Committee will, no doubt, try to suggest means whereby some of these anomalies can be reconciled and every citizen given the medical services he must have if the general health of the community is to be improved. The little volume is full of information and suggestions for all interested in medical sociology.

PARENTAL RESPONSIBILITY

Home-Life and the Community. By Leslie George Housden, M.D. (Pp. 66. 3s. 6d.) London: Eyre and Spottiswoode (Publishers), Ltd.

As Dr. Housden points out in this small book, which is sponsored by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality, much has been written and said about the subject of juvenile delinquency, but all too little stress has been laid on parental responsibility for preventing the asocial behaviour of the young. The morality of the adult population is lamentably low, and almost everyone is much more concerned with what he can get out of the future than with what he can contribute towards it. Education is given in almost everything except in the general art of living, and for this lack both school and home are responsible. Returns of losses from trading concerns, railways, etc., show what an appalling amount of petty theft goes on every day. How then can the children be expected not to steal and lie with the continuous bad example of their elders and "betters" before them? Another important cause of delinquency is that many children find the days so dull that stealing or sexual adventures are the only spice in life. Parents ought to be more concerned to see that their children's lives are more full and satisfying. Similarly clubs should satisfy the needs of the children, including the asocial youngsters, and be less concerned with the suitability of the boy or girl for the club. If children are more valued, respected, and taken notice of in the home there will be less trouble in the street.

This is a valuable tract for the times, which should be read by every interested citizen.

Notes on Books

Manual of Nutrition (H.M. Stationery Office; 1s.) has been produced by the Ministry of Food with the purpose of setting out the elementary principles for the benefit of a growing number of people whose work involves the preparation and processing of food or the planning of meals. Just as a competent aircraft pilot must understand the principles of flight, so must a caterer, a supervisor of an institution, or a cook, whether in the home, school, hospital, or canteen, understand the principles of nutrition. Without a grounding in nutrition it is impossible to know whether diets are satisfactory or not. The manual is divided into twelve lessons. The first part of the lesson deals with the various types of nutrient (fats, carbohydrates, proteins, minerals, vitamins), their energy values, digestion, human nutritional requirements, the composition of various foodstuffs, cooking, and the planning of meals and diets. The second part of the lesson consists of practical work based on the first part. There are simple questions at the end and an appendix giving the composition of the commoner foodstuffs. The text is well written and set out, the style is crisp and lucid, and the manual should be easily understood by anyone of moderate educational attainments. If it reaches the right hands, it should do much to improve the nutritional value of meals and prevent good food being wasted by bad cooking. The Ministry of Food is to be congratulated on this excellent piece of work.

We have received from the International Labour Office (3480 University Street, Montreal) a copy of Provisional Bulletin No. 7 reporting transactions of the Inter-American Committee on Social Security. This includes a paper by Dr. Martha M. Elliott on the emergency maternity and infant-care programme in the United States.

Preparations and Appliances

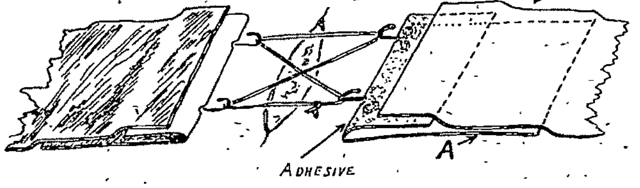
ADHESIVE CORSET DRESSING FOR GAPING WOUNDS

Dr. M. Lichtenstein writes from Glasgow:

One very annoying complication of operative and, especially abdominal surgery is the breaking down of a wound which had been stitched and considered healed. Often the starting-point of this breakdown is a ligature, sometimes a low-virulence infection of the subcutaneous fat, and occasionally excessive pressure from within the abdomen. Whatever the cause of the breakdown, it usually involves the thickness of the skin only.

The dressing of such a wound presents a complicated problem, using up great quantities of material and many reels of adhesive strapping, and taxing to the utmost the skill and resources of the nursing staff, often without achieving much progress.

The use of an adhesive "corset" dressing as described below simplifies dressing and, by relieving the tension on the skin lessens the gap between the two edges of the wound and thus accelerates healing. One important point, which cannot be stressed too much, is that the adhesive tape must be non-elastic, otherwise it would defeat its purpose. No authorship is claimed for the method, and it is being published only in the interest of those who might not have heard of it.



The Method

1. Four strips of non-elastic adhesive tape, 2 to 3 in. wide and 6 to 8 in. long, are cut.
2. Two of the strips (A) have their ends doubled back, adhesive side outwards, and with a pair of scissors two or three little holes are cut in the line of the bend, for the hooks, which are then inserted, the loops of the hooks being hidden inside the non-adhesive part of the tape, while the business ends protrude from the adhesive surface.
3. These two strips are now applied, the adhesive surface adhering to the skin all along except for the terminal 2 in., which are doubled back, reaching to within 3 to 4 in. of the edges of the wound, the hooks protruding through the holes.
4. Now the other two strips (B) are applied on top of the first ones, to cover the adhesive surface of the first from just behind the hooks and to continue along the non-adhesive surface and further beyond it.
5. A lint or gauze dressing, with or without waterproof or cotton-wool, is now applied to the wound.
6. A narrow tape or lace can now be passed over the projecting 4 or 6 hooks and drawn tight, thus approximating the edges of the wound and promoting early union.

To change the dressing one has only to unlace the narrow lace, apply a new dressing to the wound and re-lace. The whole procedure of changing a dressing is thus completed in a few minutes. The hooks should be rather big, not less than about half an inch, and can be easily procured in any haberdashery shop. Their ends have to be slightly separated to allow for the thickness of the tape.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 4 1945

THE REPRESENTATIVE MEETING

It is another sign of the return to normal conditions that the Annual Representative Meeting (reported in this week's *Supplement*) should have got back to its old place in the calendar, at the end of July, although the peripatetic habit of the Association of holding its Annual Meetings in different towns cannot yet be restored. But the fact that the previous Annual Representative Meeting took place less than eight months ago naturally lessened the amount of business to be transacted last week, and there was some speculation whether the meeting could extend itself over the three days allotted to it. Moreover, the negotiations over the proposed National Health Service, which have been the great preoccupation of recent months, were dealt with at a Special Representative Meeting held as recently as May. The proceedings last week were described as dull, pedestrian, and domestic. They might be likened to a plain between two peaks, one of which—namely, the shaping of the Association's policy on the Government proposals—has already been scaled, while the other, of unknown height and contour, remains to be tackled. On the last day of the meeting, with the Election results announced from hour to hour, this further peak suddenly loomed out of the mists to assume a precipitous and somewhat forbidding aspect. At the very moment when it was announced that the country had given a firm mandate to a Labour Government the meeting was engaged in the only internal controversy which disturbed it. A motion was brought forward from one Division which implied a criticism of the "platform" for its alleged habit of instructing, instead of being instructed by, the floor. The motion found little or no support in the meeting, but it led to a plea from a familiar quarter to have done with such carping in view of the obvious need for a united front now that a Government was to be in power with a salaried State medical service as one of its objectives.

The debate on the National Health Service proposals, to which an afternoon was devoted, covered much ground already fought over, and from which the slain had scarcely been removed. The proposal of a corporate body for the control and administration of the new service again came forward. One of the features of a debating assembly is that a settled issue has only to appear in a new form for the subject to be reopened. In this way greater wisdom may come from fuller discussion. The motion for a corporate body was again rejected, as was a motion that the control of the service should be vested in some other quarter than the Ministry of Health. The other big debate was on a proposal by Belfast that all persons compulsorily insured in the new service should have a right to "opt out," and, moreover, should receive a financial grant towards their private contract. This motion was carried by a majority of forty. The ruling of the platform was that it was not considered a reversal of Association policy. Even had it been so considered it would just have failed to secure the necessary two-thirds majority. But in view of the upsetting of the chessboard owing to the new political situation these debates seemed a little unreal.

The question of the demobilization and return of doctors to their practices was very much in mind throughout the meeting. It was also the theme of Mr. H. S. Souttar's presidential address—the shortest and most succinct address ever made from the chair of the Association. He declared that the release of men from the Forces and their re-establishment in civil practice is the most important problem facing the profession at the present time. He also spoke of the inadequacy of the Government offer of refresher courses for such released officers; he hopes to see it made into something much bigger and the starting-point of a great future system of postgraduate education in which all will share. As for re-establishment in practice, Mr. Souttar did well to point out that, whilst some fortunate ones will come back to a place waiting for them, in partnership or otherwise, many others will experience financial difficulty in resettlement, and the giving of adequate and unstinted help to these men is no matter of charity at all but the payment of a general debt and the setting of a seal to the brotherhood of the profession.

A good deal of impatience was expressed by various speakers in the Representative Body at the tardiness of release from the Forces, and a resolution was passed, without dissent, recording dissatisfaction with the present demobilization scheme. More than one speaker pointed out that the civilian medical profession is ageing; it is tired and overworked; it has had no replacements; it has given up to the Services its most active and valuable men, those in early middle age. Col. Proctor told a sombre story of the estimated present demands of the Services for medical personnel, stressing the need of the Army for the Japanese War. The Chairman of Council gave a hint of the pressure which the Association was bringing to bear upon the Government to secure speedier release and a long-term programme. The position of Service medical officers, without information as to the probable date of their return to civilian practice, was intolerable. Better news might be forthcoming in the next few weeks.

The Representative Meeting bade farewell to Dr. Peter Macdonald, who had presided over six Representative Meetings, three annual and three special—a more crowded term than has fallen to any chairman since the introduction of National Health Insurance, when nine Representative Meetings were held within about two years. For the dignity, ability, and courtesy with which he has presided he richly deserved all the praise that was given to him. He is succeeded by Dr. J. B. Miller, of Bishopbriggs—not, as some newspapers called him, the first Scottish chairman, for the retiring chairman himself is a son of Aberdeen, but the first Scottish practitioner to take that office. He will have an excellent deputy in Dr. E. A. Gregg, who has gained his spurs in his long chairmanship of the Insurance Acts Committee.

MILK STILL UNSAFE

What was on the whole rather a dull Annual Representative Meeting was enlivened by Mr. Lawrence Abel's forthright onslaught on the Government for what the Chairman of Council described as its criminal negligence in allowing the public to consume contaminated milk. Mr. Abel was all for hanging on the nearest lamp-posts ex-Ministers of Health and their permanent officials—and by this effective device of exaggeration expressed the disgust of the medical profession at the callous inertia of officialdom. As Dr. Dain observed, you can be punished for adding water to milk, but not for infecting the unprotected consumer with it. A recent answer in the "Any Questions?" section of the *Journal* has brought to light a scandal that needs exposing.

In a White Paper two years ago the Government announced its intention of taking power to exercise closer control over the quality of milk as it reached the consumer.[1] The Minister of Food was by Regulation to make it an offence to sell milk in any area which he might schedule unless the milk was either heat-treated or from disease-free animals. The White Paper was followed by a Defence Regulation (55G) giving the Ministry power to specify the areas in which only such milks might be sold. But now, as the result of an inconspicuous question and answer in these columns, we have it disclosed by a senior medical officer of the Ministry of Health that no such areas have yet been specified, and that even if any areas are specified before the Regulation is annulled they will not cover the whole country. One is left wondering what secret history lies behind this extraordinary example of departmental bad faith.

In 1943 the Government seemed to be acutely alive to the dangers of milk. In February of that year Lord Woolton, then Minister of Food, received an important deputation, led by the British Medical Association, which pressed on him the need for pasteurization of milk as the only practicable safeguard without serious disadvantages.[2] The chief spokesman of the deputation, Prof. R. M. F. Picken, now President of the Society of Medical Officers of Health, declared that few questions in preventive medicine commanded the same unanimity of approval as pasteurization. Lord Woolton was obviously impressed. He said he found it difficult to resist the weight of scientific and professional evidence which had been assembled. He recognized fully the obligation of the Government to obtain a milk supply which could do no harm, or alternatively to issue instructions as to how people could obtain reasonable security. A few months later, in July, speaking in the House of Commons, Mr. Robert Hudson, then Minister of Agriculture, declared it to be the Government's intention to prohibit in areas to be scheduled the retail sale of milk which did not belong to one or other of the three categories: T.T. milk, "accredited" milk from a single herd, and milk rendered safe by means of heat treatment. In the House of Lords Lord Woolton was even more explicit. He said that within a year and a half the Government would be able to ensure a pasteurized supply to cover the whole country where rationalization schemes of milk delivery had been introduced. In other words, wherever bulked milk was sold it would be pasteurized. The eighteen months of Lord Woolton's prediction expired last January, and it is now August. But all these fine promises have come to nothing, and the medical man who sees his patient die from infected milk is sickened by this example of political callousness.

It is true that Parliament has shown reluctance to make pasteurization compulsory, and that there are milk-selling farmers who hold the view expressed by one of them that if Nature had intended milk to be pasteurized she would have arranged that it came pasteurized from the cow. They might as well have asked themselves whether Nature intended cow's milk to be drunk by any animal other than the calf. But a wartime Government has overridden many prejudices and obscurantism among its supporters in Parliament and in the country, and it certainly seemed from the attitude of Ministers in 1943 that the battle for pasteurization had been won, and that the only obstacle was the lack of adequate facilities in some areas. In the answer given in this *Journal* which elicited the revealing comment from the Ministry of Health it was stated that "legislation" had been passed which would make it compulsory for all milk, with the two exceptions already named, to be pasteurized. The word "legislation" was not strictly accurate if an Act of Parliament is meant, but with a Government virtually having dictatorial powers the undertaking of Ministers that a certain thing will be done within a given time, which undertaking was followed by a Defence Regulation to the same effect, is in these days "legislation" enough. The Defence Regulation was issued. On January 25 of last year Col. Llewellin, who in the meantime had become Minister of Food, told the House of Commons that the new Regulation imposed restrictions on the sale of raw milk in certain areas. But apparently the Regulation is just a scrap of paper. It named certain milks which alone might be sold in specified areas, but no area has ever been specified. It would have amounted to the same thing had it named certain areas in which only specified milks might be sold, and then had failed to designate the milks. This is surrealism at its most subconscious.

The matter is the more strange because every effort was to be made to enlist the co-operation of the trade. Pasteurization admittedly adds to the cost of milk—2d. a gallon, or over £10 million a year—though the cost is trifling compared with the preventive value of the procedure. Indeed, considered in a large way, pasteurization should be regarded as a great economy for the dairying industry, eliminating much of the unnecessary duplication of milk rounds which still exists in many places. In any case the dairyman and retailer were to receive the full remuneration guaranteed by the Government to milk producers and the full margin allowed to retailers. Not only so, but the local associations of dairymen and producers, who had already been requested to prepare plans for the rationalization of retail distribution, were to be asked further to submit plans for organizing in their districts the heat treatment of milk. If the trade could not make the necessary arrangements the local authority was to step in and install and operate pasteurizing plant, being treated as wholesalers for the purpose. All this was in the White Paper. How much has been done in these directions we do not know, but the fact remains that the compulsion plainly indicated in the Ministerial statements in 1943 has not—to use the official jargon—been implemented.

---

[1] "Measures to Improve the Quality of the Nation's Milk Supply." Cmd. 6454. 1943.

[2] *British Medical Journal*, Feb. 27, 1943.

We are left to speculate what the drag on the wheel may be—departmental lethargy or the opposition of agricultural interests. The Ministry of Agriculture was never conspicuous for its zeal in the battle for clean and safe milk, but a prominent officer of the Ministry in a debate on the subject at the Royal Society of Medicine in the present year[3] said that if there were medical officers who thought there was opposition to pasteurization from the veterinary point of view they might be reassured. He left it to be inferred that in the view of his Ministry pasteurization was not an agricultural problem but a matter to be decided on medical grounds. Public health was the touchstone. Another dairying authority, Prof. H. D. Kay, director of the National Institute for Research in Dairying, has declared that the pasteurization bogy is now satisfactorily laid.[4] Careful scientific experiment extending over some years, he says, has shown that properly controlled commercial pasteurization causes practically no nutritional damage to milk. "In the near future"—this was in 1942—"it will almost certainly be a national requirement that all milk sold for liquid consumption shall either be effectively pasteurized or shall be from disease-free animals."

It is to be hoped that the new Parliament will have a quickened conscience in this matter. R. L. Stevenson said that politics is the only profession for which no preparation is thought necessary. If, as would happen in the ideal State, our new legislators underwent a period of intensive education, this should include a visit to an orthopaedic hospital or children's sanatorium. One-third of the deaths from tuberculosis in children under 5 years are due to the bovine organism—2,000 deaths a year, with, of course, a much larger incidence of invalidism and crippling. The American troops in this country have not been allowed to drink milk unless it was both from tuberculin-tested herds and had been pasteurized; yet, so far from insisting on the double protection, we do not even make universal the simpler of the two expedients. It is an amazing thing that, despite all the "safe milk" campaigns and all the apparatus of inspection and control, some part of the British public should still be exposed to the perils of raw milk. Is it too much to demand compulsory pasteurization in all areas, and, pending the availability of pasteurizing plant in any district, an official intimation to the public that milk must be boiled before its consumption is allowable?

LABOUR AND MEDICINE

We record elsewhere in this issue the successes and failures of the 37 doctors who stood as candidates in the recent Election. Of the 13 returned there are 9 Labour members, 2 Conservatives, and 1 Liberal National. Sir Ernest Graham-Little (Independent National) has been re-elected as the representative of London University. The Election results for the Combined Scottish Universities are to be announced after the *Journal* has gone to press.

Before it had been decided to hold an Election in July it was thought that negotiations with the Minister of Health on the White Paper had reached such a stage as to make the presentation of a Bill to Parliament a likelihood before the end of the recent session. There would have been one great advantage in this, and that is that the contents of the Bill would have been determined with a Government in which political forces were more or less evenly balanced. But now that the Labour Party is in power with a large majority we may find the results of prolonged and difficult negotiations "in the discard." The Labour Party's policy on a "National Service for Health" is set forth in a 24-page pamphlet published in 1943.[1] This pamphlet began with two questions: (1) "Do we need a State Medical Service?"; (2) "If so, on what lines should it be planned?" In the chapter purporting to give the reasons why a State Medical Service is necessary there are two sentences which crystallize the view of the Labour Party and provide an answer to the questions which must now be exercising the minds of all medical men in Great Britain. They are these:

> "(1) We said that the system must offer *a fair deal to doctor and patient* alike; but we found that only a system of whole-time, salaried, and pensionable doctoring would meet these requirements."
>
> "(2) Do you not agree with the Labour Party that the Medical Service should be developed, as rapidly as conditions permit, into a State Medical Service, as part of a comprehensive National Service for Health?"

It may, of course, happen that the new Government will instruct the new Minister of Health to continue negotiations at the point where Mr. Willink left off. But the antagonistic attitude of left-wing papers to the B.M.A. does not encourage this view. So our negotiators, who are all busy practising their profession at a time of acute shortage of doctors, are presumably to be faced with the prospect of going over the same ground again. According to its declared policy, the Labour Party is anxious to give a fair deal to the medical profession, and expresses the hope that "the Medical Service should be so organized as to enable the medical profession to pull its weight effectively in all those tasks of a democratic government which affect the nation's health." That doctors do want to make their weight effective was strikingly shown at last week's A.R.M. debate on the pasteurization of milk. The attitude and action of a Labour Minister of Health on this question will be for the profession a touchstone of the sincerity of the above statement of policy.

If the organized medical profession is to have a really effective voice in shaping a service which will be a potent force in preserving the health of the nation then it must be consulted at each stage of development, and must be adequately represented at all levels of administration. When we look at the Labour Party's plan of organization some things stand out on which there would be little disagreement—for example, the proposal to concentrate in one Health Ministry all those health services now controlled by other Government Departments, and to separate from the Ministry all those services which affect health only indirectly. But there is little in these proposals to suggest that the Labour Party really intends the medical man to pull his weight. He cannot do this if, for example, he is excluded from the proposed Regional Health Committees, and if he is suffered to act only in an advisory capacity at this and other levels of administration. Lastly, there are two points of policy which will be of concern and interest to both the general practitioner and the consultant. The first is a suggestion that it is not possible for it to meet the present situation by extending the National Health Insurance Scheme; the second is the statement that "before long the voluntary hospitals will come under the control of the local authorities, and [that] conditions of service and staff in all the hospitals will become standardized."

PSYCHOSIS DUE TO MEPACRINE

It is now common knowledge that the success of the Allied Forces in the Pacific in withstanding and then routing the Japanese invaders was greatly endangered in the earlier stages of the war by malaria, and that this danger has now been overcome mainly by the prophylactic use of mepacrine (atebrin). Mepacrine was first synthesized by the Germans in 1932, and its availability in 1942 (when the supply of quinine was cut off by the loss of Java) was an important factor in defeating Germany's ally. All powerful drugs have their disadvantages, and mepacrine is no exception: attention has been recently drawn again to the cerebral disturbances which occasionally follow its use.[1] These disturbances have been noted at intervals ever since mepacrine was first used, but they are not common. Thus Kingsbury[2] observed 12 cases of psychosis among thousands of Malayans who had been treated; and Hoops[2] had only one case of mental excitement among 1,207 cases of malaria treated. On the other hand, during the Ceylon malaria epidemic of 1935 Briercliffe[2] recorded that 15 cases of delirium developed among some hundred persons who took the drug by mouth. Bispham[3] in 1941 analysed the toxic effects seen when 49,000 cases of malaria had been treated with mepacrine; he noted that cephalalgia, mental depression, delirium, psychoses, and convulsions may occur, but the rate of incidence was very low. Field[4] estimated the occurrence of mepacrine psychosis as less than 0.1% of cases treated; the symptoms began just before or just after the end of treatment; the patients showed signs of excitement, confusion, or even mania, and the symptoms gradually subsided, after having lasted for approximately one week. Cerebral disturbances have occasionally occurred in the Australian Forces, but they have been rare and have usually appeared in men who had taken excessive amounts of mepacrine during self-medication.

The cases reported in a recent paper by Gaskill and Fitz-Hugh[1] of the American Army occurred on fairly low doses—namely, 2.1 g. given during about 6 days in the treatment of acute attacks of malaria. The symptoms, though interesting, were quite rare, affecting only 35 men out of 7,604 who were treated—i.e., only 0.4%. The onset took place between the third day after the beginning of treatment and the twelfth day after its end. There were two main types. In one there was an abrupt change of behaviour with an increase in motor and psychomotor activity; sometimes hallucinations, delusions, and disorientation occurred; the general impression was of euphoria and expansiveness. In the other type there was a gradual and insidious onset of retardation of the mind and confusion; there was a gradual clouding of the sensorium, with disorientation and loss of recent memory; the patients were withdrawn and seclusive; and the general picture was one of bewilderment and fearfulness. Laboratory tests showed nothing abnormal. Treatment was palliative. Thirty-three of the 35 patients recovered completely, the average time needed being 23 (8–85 days). When the return to normal behaviour began it was completed quickly in one to two days. Subsequently half of these patients were given the same course of mepacrine again, and no serious symptoms occurred. As regards diagnosis, the chief point is to exclude cerebral malaria, which should be suspected in all cases of peculiar mental reaction in the Tropics until disproved. In psychosis due to mepacrine it should be noted that the patients have recently received antimalarial treatment, that the slight initial fever which may be present in a few cases subsides in 12 to 24 hours, that the symptoms are all psychiatric, that the behaviour pattern remains constant, and that there is no objective neurological disturbance. The explanation of these cases is not clear. It is known that very large doses of mepacrine cause mental disturbances even in normal persons; but in the patients just described the dose was not abnormally high. Probably a combination of mepacrine, malaria, personal idiosyncrasy, and the hardships of warfare may be involved. Whatever the cause, it should be remembered that these toxic effects are rare and relatively unimportant compared with the damage which can be caused by malaria. It is interesting and useful to know that they can take place, but their possibility should never deter the confident use of this valuable prophylactic and therapeutic antimalarial compound.

CARE OF THE AGED

Realization that we are faced with the prospect of an increasing proportion of the aged in our population has had medical and social effects, which are naturally intertwined. The books reviewed in our columns show how much attention is being paid to the study of "geriatrics," while recent correspondence in the *Times* (July 7, 9, 11, 12, 14, 16, 17) gives an impressive idea of the efforts now being made to grapple with the social problems involved. Indeed, so many agencies seem to be at work that there may be some risk of overlapping, for there is little evidence of co-ordination in these beneficent enterprises. It is, however, clearly recognized that different types of homes are needed for the widely different classes to be catered for, varying from complete hospital facilities to provision for single persons or married couples. The Westminster Housing Association, for instance, prefers mixed communities to a segregated colony of aged people alone. There is a large class who long for the independence of their own room and latchkey, with their own "bits and pieces." Institutional life is not for them if they are to remain in any way content, and this other plan is the one favoured by the Church Army housing committee. Now that interest has been so thoroughly aroused and the importance of the subject realized one may fairly hope that funds will be forthcoming and that our national capacity for adapting means to ends will declare itself in this much-needed work.

The Central Medical War Committee is informed by the Director-General of Medical Services of the R.A.F. that under Class A of the reallocation scheme Groups 1 to 8 will be released by September, Groups 9 and 10 during September, Groups 11 and 12 in October, Groups 13 and 14 in November, and Group 15 in December. This is the minimum rate of release, and if the rate of general release in the Service is speeded up the rate of release of medical officers will be speeded up also.

THE RETURN OF THE DOCTOR*

BY

H. S. SOUTTAR, C.B.E., M.Ch., F.R.C.S.
President of the British Medical Association

I am confident that I shall meet with general support if I say that the most important problem facing our profession at the present time is the return of medical men from the Forces. It presents two aspects—their release from the Forces and their establishment in practice—and as both these aspects have engaged the attention of the Association for many months I felt that they would form an appropriate subject for a short presidential address. Both aspects involve problems of the greatest complexity to which I can refer only in the briefest outline, but I hope to be able to convince you that these problems are being attacked with the whole power of the Association and that with the good will of all of us they will be solved.

Classes for Release

Release from the Forces must follow the plan laid down for demobilization in general and falls into two classes: Class A being the general routine, Class B dealing with special cases. So far as is possible releases should be in Class A, which depends entirely on age and length of service, for any departure from this means that men will be delayed from release in their proper category. Even, however, where a category is due for release, and particularly in the case of specialists, it may be impossible to effect this without substitution. For this reason it is imperative that the recruitment of young practitioners should continue, and that all the available specialists up to the age of 35, or in some cases even 40, who have not already served in the Forces should be prepared to take their turn.

In Class B release may be obtained for those who are urgently needed for work of national importance—in some cases for civilian needs of extreme urgency, in others for the teaching staffs required for the training of students, both undergraduate and postgraduate. These must, however, be jealously guarded, as a large number of releases out of turn in Class B means a delay in Class A. Released doctors will fall into three classes.

Class I consists of those who joined the Forces soon after qualification. In general these men have held a short hospital appointment, but before joining up they had only a very limited clinical experience, and they require further experience under supervision before engaging in practice. Others in this group were on their way to a university degree, but were prevented by recruitment from achieving it. It is the intention of the Government that for all these there should be available hospital appointments carrying a salary of £350 a year and all found, and with special family allowances for those who require it. Such an appointment held for six months, with its opportunities of clinical experience under skilled supervision, would be of inestimable value at such a critical moment in a young doctor's career. If he wishes to go into practice it will give him the opportunity of looking round and finding a congenial opening; if he wishes to take a higher degree it puts him well on the way towards this. It is estimated that the number of individuals in this class is now about 10,000, but, of course, they will only appear in limited numbers as demobilization proceeds.

Class II consists of those who were engaged in general practice before recruitment. Naturally their first anxiety will be to get back to their practices, and to this they will undoubtedly be urged by their overworked colleagues. Many of them will, however, feel the need for refresher courses so that they may regain their clinical touch in civilian work, which is so utterly different from work in the Army, and so that they may learn something of recent advances in medical science. The Government offers a completely inadequate period of two weeks, but they agree that the refresher course may be taken at any time within a year of release, that travelling and subsistence expenses will be paid, and that the cost of employing a locum will be provided if necessary. Whatever the views of the Government, we hope that the hospitals will see that adequate courses of at least a month are provided, and that these are so arranged as to meet in every way what is needed. The urgent need for our future medical service is to be efficient. One may indeed hope that such refresher courses may only be a starting-point of a great future system of postgraduate education in which all of us will share, and that they may initiate the close co-operation between our hospitals and general practice to which we look forward in the future.

Class III consists of those who are aiming at a specialist career and who wish to pursue it on their release. For them posts of the registrar type will be found, especially in the teaching hospitals, and they will be paid £550 a year with board and lodging. Arrangements for these appointments—and this applies also to Classes I and II—will be made through the universities, and it is already generally agreed that the experience which the candidate has already gained will be counted towards the requirements for entry to the higher examinations, and will receive consideration from those whose duty it is to conduct examinations.

Back to Practice

There still remains the problem of establishment in practice, and here the responsibility shifts from Government Departments and examining bodies, and must be accepted by ourselves. It is we who must make the path smooth for the returning doctor, and more especially for those who are entering general practice for the first time. Some fortunate men will return to a share in an established practice, where they will be welcomed with more than open arms. Some 10,000, however, will have to find openings, and without our help they may not find it too easy. Much careful study has been given to their problems, and they will find the Association ready with full information of the openings available and prepared to give not only advice but very substantial help. Assistantships can be arranged at once, and if these mature into a mutual desire for partnership provision can be made for the necessary finance. If, for example, a doctor without capital desires to purchase a practice arrangements can be made through the services of the Medical Insurance Agency by which he can obtain the whole sum required at a low rate of interest. Such an arrangement offers a double advantage, for not only does it benefit the young practitioner setting out on his career, but it also relieves the anxieties of the older man who has held the fort so magnificently against all the odds of age and overwork until the young man could return.

There will still remain difficult cases in which all the help that can be given from official sources must be quite inadequate. To meet such cases in the early days of the war we instituted a Medical War Relief Fund, which has reached the sum of £54,000, of which £24,000 has already been spent in relief. After what I have seen for myself of the amazing relief which has been brought to individual cases by this fund I would urge that now is the moment to raise it to an amount commensurate with the occasion, and that we should use this opportunity to prove to those who have given such great service to their country that we appreciate what they have done and will give them all the help that they have so fully earned.

Here is no question of charity; rather is it the payment of a debt that we owe; but most of all we should be setting our seal to the brotherhood of our profession and to our determination that those who have suffered through no fault of their own shall be able to turn for support to those of us who have been more fortunate. I should like to see the fund raised to such a sum as will ensure that we shall be able to give to all those who need it the adequate and unstinted help which I know we all desire. Ours is a great profession. Let us see to it that in the years to come it is a great brotherhood.

An educational lecture on oxygen therapy is available to medical superintendents, sister tutors, and other lecturers. It traces the history of oxygen therapy, the principles and applications, and the forms of apparatus in use to-day. The text is supplied in typescript written in a style suitable for presentation to doctors, nurses, and students, and takes about 40 to 45 minutes in all. A series of lantern slides accompanies the text and illustrates the manufacture of oxygen, the installation of oxygen in hospitals, and various types of apparatus used from the most primitive form to the latest design. Details of the lecture—which is loaned without charge—may be had from Oxygenaire Ltd., 8, Duke Street, Wigmore Street, London, W.1.

---

* A brief address on his election to the Presidency of the Association at the Annual General Meeting on July 25.

THE GENERAL ELECTION

MEDICAL MEMBERS OF THE NEW PARLIAMENT

Of the 37 medical men and women who stood as candidates for Parliament at the recent General Election 13 were elected. Of these 9 are members of the Labour Party, 2 Conservatives, 1 Liberal National, and 1 Independent National. (The result of the Combined Scottish Universities Election had not been received at the time of going to press.)

The following 6 medical candidates, who were members of the last Parliament have been re-elected: Sir Ernest Graham-Little, Dr. L. Haden Guest, Dr. H. B. Morgan, Sir Henry Morris-Jones, Major B. Neven-Spence, and Dr. Edith Summerskill.

SUCCESSFUL CANDIDATES: POLLING FIGURES

WEST HAM (SILVERTOWN):	
Dr. L. Comyns (Lab.)	**9,358**
Squadron Leader E. Elverston (C.)	494
Capt. A. Davies (Ind.)	401
LONDON UNIVERSITY:	
Sir Ernest Graham-Little (Ind. Nat.)	**7,618**
Mrs. Mary Stocks (Ind. Prog.)	7,469
ISLINGTON (NORTH):	
Dr. L. Haden Guest (Lab.)	**23,234**
Capt. C. Rhys (C.)	11,240
BARKING:	
Dr. Somerville Hastings (Lab.)	**24,504**
K. E. B. Glenny (C.)	5,593
C. H. Willcock (L.)	4,674
ST. PANCRAS (SOUTH-EAST):	
Dr. S. W. Jeger (Lab.)	**10,030**
Sir A. Beit (C.)	5,320
Mrs. A. Blackman (L.)	1,474
ROCHDALE:	
Dr. H. B. Morgan (Lab.)	**22,047**
Wing Cmdr. E. M. Nicol (C.)	16,852
C. G. C. Harvey (L.)	10,211
DENBIGH:	
Sir Henry Morris-Jones (L. Nat.)	**17,023**
Wing Cmdr. G. Evans (L.)	12,101
Lieut.-Cmdr. W. L. M. Jones (Lab.)	11,702
ORKNEY AND SHETLAND:	
Major B. Neven-Spence (C.)	**6,304**
Major J. Grimond (L.)	5,975
P. J. L. Smith (Lab.)	5,208
PRESTON (2 seats):	
Squadron Leader S. Segal (Lab.)	**33,053**
J. W. Sunderland (Lab.)	32,889
Major R. Churchill (C.)	29,129
Capt. J. Amery (C.)	27,885
Flight Lieut. J. M. Toulmin (L.)	8,251
P. J. Devine (Comm.)	5,168
YORKSHIRE, WEST RIDING (PUDSEY AND OTLEY):	
Lieut.-Col. M. Stoddart-Scott (C.)	**22,755**
Major D. W. Healey (Lab.)	21,104
Brig. T. Clarke (L.)	8,592
STOKE-ON-TRENT (HANLEY):	
Dr. B. Stross (Lab.)	**21,915**
Capt. J. P. A. L. Doran (C.)	10,313
FULHAM (WEST):	
Dr. Edith Summerskill (Lab.)	**19,537**
Wing Cmdr. P. B. Lucas (C.)	12,016
HERTFORD (BARNET):	
Dr. S. J. L. Taylor (Lab.)	**17,764**
Brig. A. E. J. Clarke (C.)	17,082
Miss J. M. Henderson (L.)	4,495

Medical Candidates Not Elected

The following members of the medical profession were defeated at the polls. Several had previously represented or contested either the same or other constituencies. An asterisk denotes that a candidate sat in the last Parliament.

Surg. Lieut.-Cmdr. R. F. B. Bennett (C.), Woolwich (East).
Mr. L. Graham Brown (L. Nat.), Bedford (Luton).
Lieut.-Col. Leonard F. Browne (Lab.), Cumberland (Penrith and Cockermouth).
Flight Lieut. H. B. O. Cardew (Lab.), Somerset (Weston-super-Mare).
Dr. D. J. Cavanagh (Irish Nat.), Londonderry.
*Sir J. Douglas Cooke (C.), Hammersmith (South).
*The Rt. Hon. Walter E. Elliot (C.), Glasgow (Kelvingrove).
Major G. A. D. Gordon (L.), Richmond.
Dr. B. Guyster (L.), Leyton West.
Surg. Cmdr. J. J. Hayward (Nat.), Monmouth (Abertillery).
Dr. Charles Hill (Ind.), Cambridge University.
Dr. T. Rowland Hill (L.), Cornwall (Camborne).
Dr. Elizabeth Jacobs (Lab.), St. Marylebone.
Dr. E. F. St. J. Lyburn (Ind.), Kent (Tonbridge).
*Dr. R. D. MacIntyre (Scot. Nat.), Lanark (Motherwell).
Dr. G. C. Milner (Ind.), Kent (Orpington).
Dr. D. Stark Murray (Lab.), Richmond.
Dr. W. B. J. Pemberton (L. Nat.), Bermondsey (West).
Dr. Dorothy A. Sharpe (C.W.), Chelsea.
Major R. Scott Stevenson (L. Nat.), Fife (West).
*Dr. W. S. Russell Thomas (L. Nat.), Southampton.
Flight Lieut. R. N. Tronchin-James (L.), Reading.

BRITISH MEDICAL ASSOCIATION

Scholarships in Aid of Scientific Research

Scholarships

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: an Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four research scholarships, each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession. The scholarships will be tenable for nine months in the first instance, commencing on Jan. 1, 1946. A scholar may be reappointed for not more than two additional terms of one year each. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces, or hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment do not interfere with his or her work as a scholar.

Conditions of Award: Applications

Applications for scholarships must be made not later than Saturday, Dec. 1, 1945, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS

This society held its 33rd meeting in Edinburgh under the presidency of Mr. Norman Dott on June 1 and 2, 1945. It is proud of its record, having met at least once in each of the war years. Naturally, difficulties of travel prevented the usual round of visits which the society used to pay, and all its previous wartime sessions have been in London or in Oxford. The Edinburgh session was a great event, for not only were the papers of outstanding scientific interest but the feeling of tension and urgency that marked late occasions was abated. A few papers of special importance were Prof. D. K. Henderson's on the advantages of prefrontal leucotomy, Dr. Paterson's on psychiatry on an organic basis, the description by Mr. Alexander of the operation devised by Mr. Dott and himself for the relief of spinal compression in Pott's disease, and the account given by Mr. Dott and Dr. Blackwood of the clinical and pathological effects of too-heavy doses of *x* rays on the brain and of radiosensitivity of meningiomas. Since these and other papers of equal merit will be published eventually there is no need to enumerate them in full. By special request Lieut. Pudenz, of the U.S. Naval Medical Service, showed his fascinating colour film of brain movements during head trauma. The collaboration of the British Medical Research Council and the American Board of Scientific and Medical Research had made this visit possible. It was greatly valued by all who took part.

Correspondence

Toxic Properties of Sting-ray's Sting

SIR,—In a recent paper by Dr. E. W. Gudger entitled " Is the Sting-ray's Sting Poisonous ? A Résumé showing the Development of our Knowledge that it is Poisonous "[1] a full account of my work on the spine of *Trygone pastinaea* has been given, but the author concludes this description with the following remark: " While Evans made no experiments as to the poisoning nature of the spine and the products of the glandular tissue, he submits that the acute pain, inflammation, and paralysis are similar to the symptoms produced by the stings of other venomous fishes with which he experimented." Living trygones are rare on the East Coast fish markets and my material has been usually obtained from the South Coast and forwarded to me by the staff of the Ministry of Agriculture and Fisheries who live in those parts. This accounts for the omission of experimental evidence of the toxic properties of the stings.

Recently Fl. Lieut. J. Fawcitt, of R.A.F. India Command, has sent me some very valuable observations on the effects of wounds by the cordal spine of the sting-ray, prevalent in the Bay of Bengal. He has given me permission to publish his clinical notes on cases he has observed.

> " During the four months I was in charge of a sick-quarters on the shores of the Bay of Bengal I saw and treated a number of cases of sting-ray and jelly-fish stings. The cases described below are typical of those observed by other medical officers in the area, as well as by myself.
>
> While bathing thigh deep in the sea I was stung on the right ankle by a sting-ray. The weapon was not left in the wound. There was a stab incision just in front of the internal malleolus of the right ankle. There was practically no haemorrhage from the sting, and the edges of the wound looked bluish and bruised. The initial pain was severe and localized, though the whole limb felt numb. Three-quarters of an hour after the sting there was onset of pain on respiration, which rapidly increased in severity until even shallow breathing was extremely painful. This was followed in an hour and a half by intermittent spasms of the abdominal muscles, which rapidly increased in frequency until they became almost continuous. In addition there were extreme restlessness, nausea, tingling of the extremities, and slight dizziness.
>
> Within four hours the pain was so severe that morphine was necessary, and half a grain was given orally. This was followed by two attacks of vomiting, and the pain was so little relieved that a further third of a grain was given hypodermically. Following this a certain amount of restless sleep was obtained during the rest of the night. After fifteen hours intercostal pain on respiration and marked spasm of the abdominal muscles were still present, and did not disappear for three days. Constipation was an added discomfort.
>
> Though the site of the sting was never intensely painful except immediately after the initial stab, a chronic ulcer developed, which took 16 days to heal. Though it is difficult to view pain objectively in oneself, other victims have unanimously agreed with me that it was the most severe pain they had ever experienced."

The description of a case of a man stung severely by jelly-fish is also given in the same letter as follows:

> " An airman was stung on both thighs by a large jelly-fish, and was admitted to sick-quarters within twenty minutes. He described the sting as being like red-hot wires drawn across the front of his thighs. He was a man of poor physique; there was intense pain with a moderate degree of shock; temperature 99° F. ; pulse 100. On the anterior surface of his thighs there were large, reddened, oedematous patches, with cord-like raised areas where the tendrils of the jelly-fish had swept across them. There was already marked abdominal rigidity, respirations were shallow and rapid, and there was intense intercostal pain.
>
> For want of any other remedy spirit. ammon. aromat. was immediately applied to the stings, and this completely abolished the local pain though it did not affect the generalized symptoms. These were relieved by a third of a grain of morphine hypodermically, though a further injection was necessary six hours later. Eighteen hours after the sting acute intercostal and abdominal pain were still present; the patient had vomited twice during the night, and complained of nausea and restlessness. The symptoms gradually wore off, but did not finally disappear until the sixth day.
>
> There were two striking factors in this case that I found present in all severe cases of sting-ray and jelly-fish stings that I saw: (1) abdominal rigidity of a degree that is only normally seen in an acute abdominal catastrophe; (2) constipation that was so stubborn that an enema was necessary on several occasions."

These observations are very important, and they tend to show that the poison in both the sting-ray and jelly-fish are very similar in their clinical effects. It is known from the work of many investigators that there are two toxic substances in the sting of jelly-fish—namely, congestin and thallasin—which will be found fully described in the classic work by Marie Phisalix, *Les Animaux Venimeux et les Venins.*

It can be argued from this that, although the venom of the sting-ray has not been examined in the same way as that of the jelly-fish, it is probable that it is of the same nature. It also tends to disprove the contention of earlier observers that the sting of the ray was poisonous only on account of the introduction of the slimy mucus on the skin.—I am, etc.,

Beccles. H. MUIR EVANS.

Excision of Patella

SIR,—When Mr. H. A. T. Fairbank writes or speaks, those of us who are younger in years and experience read or listen with respect and affection, for his power of critical analysis blended with a long experience has always contributed to any argument in which he has joined.

Despite my training in the conservative Liverpool School of Orthopaedics, I cannot help feeling that his letter (July 14, p. 62) condemning excision of the patella is a little too sweeping. He concludes the letter by stating, " I am convinced that the best advice one could give a young surgeon would be to learn to suture the fragments of a fractured patella with accuracy and not to resort to excision of the bone in the hope of getting a rapid result." My commentary on this sentence is the following three cases.

In 1929, when I was his registrar, I assisted Mr. Watson-Jones, who is, as everyone knows, a very skilled operator, to suture a simple, transversely fractured patella in a man aged about 60. The immediate result of this operation delighted the patient, the surgeon, and his registrar. Three or four years later I happened to come across the patient while doing an evening surgery for his panel doctor. The man had much pain and crepitus. My disappointment was so great that the case has never left my thoughts whenever the subject of the treatment of a fractured patella has to be discussed.

The second case was a patient of Mr. Ollerenshaw's in 1939, who again had an accurately sutured transverse fracture of the patella. A few months after returning to the comparatively light work of a chauffeur-gardener he slipped and refractured the bone. This is the second disappointment, and although excision was then carried out the poor result cannot be blamed on the excision so much as the fact that he had two traumata and two operations.

The third disappointment was one of my own patients who in 1944 suffered a simple transverse fracture without any separation and was treated conservatively by plaster-of-Paris splintage. Some six months later he had pain and weakness, not due to limitation of movement, but due to arthritis. A skiagram revealed lipping of the articular surfaces of the patella in the line of fracture—i.e., the gliding surface was irregular despite the most perfect position that any surgeon could obtain.

These three cases would never enter into anybody's statistics of end-results because they are distributed among three surgeons, but they suggest that accurate suture of the fragments does not necessarily lead to a good result. These and many other cases force me to accept the fact that, after a patella has been fractured, only a very small number of patients regain a good, strong, fully movable, painless knee; and it is with this background that the results of all forms of treatment must be compared. This apparently pessimistic view will probably be contested. I suggest that it is not pessimistic, but accurate.

When considering whether excision or suture is better we must also realize that in the majority of cases a patient, though possessed of a symptomless knee prior to the fracture, is approaching or has attained the age when *x* rays reveal the bony changes known as osteo-arthritis. In these patients even a simple contusion of the knee without any fracture not infrequently leads to as much pain, weakness, swelling, and sometimes loss of movement as in cases of a fracture.

When a patella is excised for osteo-arthritis or rheumatoid arthritis the patients start off with an already painful, weak, and perhaps stiff knee, and although they know just as well as the critical surgeon that after the operation the knee is not perfect these patients are pleased because they have a good deal less pain. It is true that some knees are weaker than others after excision of the patella.

---

[1] Reprinted from *Bull. Hist. Med.*, 1943, 14, No. 4.

I cannot agree with Mr. Fairbank that it is only essential to repair the hole left in the capsule. I regard it as imperative to make what I like to term a "false ligament" joining the lower end of the central portion of the quadriceps tendon and the upper end of the patellar ligament. This false ligament is made up of overlapped and rolled extensor aponeurosis plus silk or thread continuous suture. It is designed to glide over the patellar portion of the femur in order to replace the lost bony pulley, and the more carefully one constructs this ligament the more satisfactory is the voluntary extension of the knee afterwards.

Finally, remembering that the knee cannot ever be as powerful as the undamaged knee, it is important to explain to the patients that no matter what we do to the knee it can never be perfect, but that our treatment will give the best possible result. We must be careful to point out that this partial imperfection will include some weakness. Otherwise we shall have the same story as was told by the first patient whose patella I excised. I regret that I had not then realized the importance of warning the patient of what the future would hold for him. After he had recovered from the immediate injury and operation he went to his trade union's convalescent home at Llandudno for a fortnight, and on his return told with delight how he had been able to climb up the Great Orme. However, a few weeks later he returned, complaining of his inability to walk up and down a flight of stairs at his work. It is not fair to say that he was malingering; but he realized his knee was weak—just as I knew it would have been weak after suturing of the patella—and feeling the economic insecurity that makes life so difficult for all workmen he imagined himself much more disabled than he was in reality.—I am, etc.,

Manchester. W. SAYLE CREER.

SIR,—Mr. Fairbank's letter (July 14, p. 62) with its admirable exposition on the present position of excision of the patella is timely and welcome. I can confirm the results of Mr. Fairbank's experience where so many patients are now classified as *permanently partially disabled* as a result of the operation. The results of immobilization of the bone fragments by suture never produced the disabling results one so often sees following the excision method. I meet so many of the younger inexperienced generation of surgeons who are imbued with the conviction, acquired from textbooks and current literature, that excision of the patella following fracture is the *only* treatment worth considering, and they await with bated breath an opportunity of putting their belief into practice.

In a simple fracture by direct violence with stellate comminution of the patella the bone fragments are usually enclosed in the containing "sheath" limited by the boundaries of the periosteum and articular cartilage; if treated conservatively by rest a good functional result is usually obtained. In my experience it is seldom that bone fragments perforate the "sheath," but if they do so the knee-joint must be opened and the fragments removed.

With a transverse simple fracture caused by muscular violence it is not always appreciated that the aponeurosis fused with the periosteum, covering the subcutaneous surface of the patella, is ruptured at a much lower level than that of the bone fracture. The operation I have done over a long period of years has been the approximation of the fractured bone surfaces by two interrupted chromic catgut sutures of 20 days' absorption, care being taken not to encroach on the articular surface of the patella—i.e., *into* the knee-joint; even as important is the repair of the torn aponeurosis by interrupted catgut sutures. My results have been good. Few have had much limitation of knee-joint movement; in no case has there been a sequel of infective arthritis.

Most elderly doctors can testify to acute disappointments following the premature booming of some new method of treatment, medical or surgical, which subsequent events proved limited in value or worthless. I would make a plea for more restrained optimism where a new surgical operation is advocated without the justification of an ample test-time limit. To mention one such case:

A medical man suffering from a duodenal ulcer had a short-circuiting operation done by a well-known surgeon who had recently returned from a surgical tour in the U.S.A. During his travels the surgeon saw a new type of operation which so appealed to him that he abandoned his old well-tried and successful technique for the new method. The results were disastrous to the patient in question, who, for over 20 years until he died, expressed his disappointment forcibly in these words: "I am the victim of a fashion in surgery; if Mr. 'X.' had only done his ordinary operation and not the new method he saw in the U.S.A. I would not be in the plight I am now in." The surgeon soon returned to his old technique.

Surely it is reasonable to ask that surgical innovations should not be broadcast, and, in particular, not included in teaching textbooks until the operation has been evaluated by some time factor. This could be done under the aegis of a reputable surgical "society," which could refer it to a committee of inquiry; they could arrange for an adequate number of operations to be done, the results checked and finally reported upon after an adequate time has elapsed. Only upon confirmation of results should an account of the new operation be included in a teaching surgical textbook. Of course the surgical society concerned must take care that the originator of the innovation should, on confirmation, be accorded the full credit for the discovery. I have no hesitation in saying that had this procedure been followed in excision of the patella for fracture, a large number of patients—Service men and civilians—would have been spared a severe permanent disability.—I am, etc.,

R. J. WILLAN.

SIR,—Mr. Fairbank states a strong case for the adoption of a conservative, or at any rate a critical, attitude towards excision of the patella, partial or complete, for injury.

I should like strongly to support his conclusions. My reason for so doing is based on a fairly extensive experience of isolated cases and on my observations at a convalescent depot in East Anglia during the period 1942-3. At the latter, at from 2 to 12 months after operation I noted some 13 consecutive cases of complete excision of the patella for fractures. The operations had been carried out by various surgeons in the area. Of the 13 patients, three were returned to duty in Category A, two were boarded as unfit for further service, and the remainder suffered from varying degrees of disability. The disability was usually the result of imperfect control of the final degrees of full, firm extension. These failures may no doubt be attributed to faulty technique or to unsatisfactory after-treatment; the fact remains that it is difficult to assure a perfect result. It was noticeable that even in men with good function the thigh on the side of the excision remained appreciably smaller in circumference than that on the sound side.

In compound injuries, and in some instances of gross comminution, excision may be the best course. In most simple fractures it seems a confession of incompetence on the part of the surgeon to remove a useful bone because he is not mechanic enough so to fix the fragments that approximate restoration to the normal can take place. The application of the term "useful" to the patella may be justified on account of its service in the extensor control of the knee, its protective value, and its cosmetic significance.—I am, etc.,

Oxford. C. MAX PAGE.

Standardization of Instrument Fittings and Apparatus

SIR,—There was some discussion in your columns a short time ago about the advantages which British medicine would enjoy from the adoption of the metric system. Reform is also badly needed in another direction, and that is in the matter of standardization of surgical instrument fittings and apparatus. It is encouraging to note in a recent answer in "Any Questions?" that the standardization of needles and mounts is already on the way (June 30, p. 932). For such standardization to be of value, however, it must find general acceptance, and it is in this sort of thing that totalitarian countries enjoy an advantage. I understand that some years ago the manufacturers in this country were forced to make other sizes to meet foreign competition, having already agreed upon the S.I.M.A. fitting as a standard one. There should be little difficulty over standardization, however, once the profession has appreciated its convenience, or rather its lack of inconvenience.

At present the variety of fittings in use is bewildering, and confusion arises especially in the matter of syringes, cannulae, and needles, in the bayonet and other fittings for the injection of oily fluids and local anaesthetics, and in intravenous apparatus. An instrument catalogue may illustrate a long series of adaptors to make different sizes of mounts fit different sizes of needles. Such adaptors, moreover, result in clumsiness and an increased risk of leaks, and are very apt to be missing when wanted.

Intravenous infusions of various kinds are now given with great frequency, and with suitable apparatus are simple and safe. It is annoying, however, to find, after successfully inserting a needle into the more or less empty and collapsed vein of a shocked patient, that the available nozzle will not fit the needle, and that a connexion has to be made by threading rubber tubing over the needle. This often results in the needle being forced through or out of the vein, or the delay allows clotting to occur in the lumen of the needle. It may also be found that different types of apparatus are in use for the giving of blood, plasma, saline, and glucose. It is true that with a little ingenuity one type of apparatus may be connected up to another by such measures as inserting needles into tubing, and sometimes it is possible to transfer fluids from one container to another. All this, however, means increased risk, and some recent reports, such as those of fatal air embolism due to transfusion, or fatal sepsis due to the intravenous injection of penicillin, show the risks which already exist in intravenous therapy. All who have used the apparatus standardized by the transfusion services throughout the country since the war will agree that it is remarkably simple and satisfactory to use, and with the improved materials available in peacetime it would be a great convenience if all intravenous fluids could be given with a similar standardized apparatus.

It unfortunately often happens that the ingenuity of inventors and manufacturers produces apparatus which is an improvement on that previously available but which requires replacements and refills of non-standard size. Surely standardization need not curb commercial progress. The time seems suitable for an investigation of the whole problem. Once standard fittings have been introduced, adaptors could continue to be made till existing stocks of non-standard apparatus have been used up.—I am, etc.,

Birkenhead. **BRYAN WILLIAMS.**

Cerebral Fat Embolism after E.C.T.

SIR,—The case of cerebral fat embolism following electrical convulsion treatment reported by Drs. Meyer and Teare (July 14, p. 42) is of interest, since a somewhat analogous case was reported by A. Karlen (*Acta chir. scand.*, 1942, **87**). Karlen described pulmonary and cerebral fat and marrow embolism in a man of 25 years who had violent convulsions after an injection of "per-abrodil" (a non-oily fluid) into the sacral canal; the man died in a uraemic-like state. Necropsy revealed ruptures and haemorrhages in the abdominal wall muscles, the lumbar and psoas muscles, diaphragm, etc. The muscle ruptures occurred during the convulsions. No fractures were found, but the vertebrae were not examined in detail.

It is known that fractures of the vertebral bodies may occur during severe convulsions, and Karlen was careful to point this out and cited the relevant authorities. Karlen considered that the fat embolism arose from such fractures. Such vertebral fractures may not be evident on inspection; section of the vertebral bodies may be necessary for their detection. Violent convulsions, as in convulsion therapy, may actually cause compression fractures of the vertebrae (see case report by Stalker, *Lancet*, 1938, **2**, 1172). In a series of 51 cases of psychiatric disorders treated by convulsion therapy the incidence of compression fracture of the vertebrae was no less than 43% (Polatin *et al.*, *J. Amer. med. Ass.*, 1939, **112**, 1684).

The post-mortem examination notes of the case reported by Drs. Meyer and Teare state that a careful examination of the spine, etc., was made, but no fracture was detected. Unless the vertebral bodies were sawn through and examined the possibility that a fracture was overlooked cannot be ruled out. It would be of interest, therefore, to have more precise information on this. The point is of interest, since the view has long been held that concussion could give rise to fat embolism. The evidence is slender. In an extended series of investigations over a period of five years I was quite unable to substantiate this view. I have collected a large series of cases of fat embolism; fat embolism was never found without fracture or surgical trauma of bone or trauma of fatty tissues. It is hoped to publish this series of cases shortly.—I am, etc.,

R. DRUMMOND,
Late Assistant Lecturer, Department of Pathology,
Cardiff. Welsh National School of Medicine.

Treatment of Coma

SIR,—The paper on arsenical encephalopathy by Col. Ransome and Capts. Paterson and Gupta (May 12, p. 659) is very valuable. They profess great faith in the treatment of comatose patients by postural "decompression" and advocate it for cerebral malaria, the coma of hyperthermia, arsenical encephalopathy, and, perhaps lead encephalopathy. Also they direct that convulsions and restlessness should be "ruthlessly" suppressed. Many years ago I tried nursing cases of obstinate hyperthermic coma in the sitting position, with undoubted improvement as compared with other cases lying down, but with results less brilliant than shown by the authors. As with them the underlying idea was to prevent pulmonary oedema.

Not long ago it was suggested that patients developing anaesthetic convulsions should be treated by raising the head, and almost complete control of the fits was claimed for this method. The upright-sitting position certainly has no effect on the convulsions of hyperthermia, so perhaps they differ from anaesthetic convulsions in causation; but the two conditions have much in common nevertheless.

Ransome, Paterson, and Gupta recommend the use of soluble hexobarbitone for the control of convulsions in the cases of coma treated by them. No doubt this therapy is based on the recognized methods for combating anaesthetic convulsions. I would hesitate to use soluble hexobarbitone in these cases (encephalopathies), for I have seen prolonged coma, uninterrupted except by death, following minor operations in three cases after 1 to 3 grammes of the substance intravenously. I considered this too "ruthless." I have not seen any fatal results after the intravenous administration of evipan sodium, though this was a very popular anaesthetic at one time. In my opinion the inhalation of oxygen from a mask—Cowan and Mitchell type when available—is an invaluable adjunct to other forms of treatment, and the oxygen appears to have an anticonvulsant effect, but prolonged use may be necessary. Oxygen appeared to me to be kinder to the suffering encephalon.

The authors ask for reports from other people on the effect of their postural drainage, which is my excuse for this note. Much of the outstanding success justly claimed by the authors —as they admit—is due to the superb nursing skill enjoyed by their patients.—I am, etc.,

FRANK MARSH,
Pathologist, Anglo-Iranian Oil Company.

Abacterial Pyuria

SIR,—I read with great interest Mr. Hugh Donovan's article on abacterial pyuria (July 7, p. 12), as many cases of this nature presenting a urethral discharge attended my venereal clinics in the Middle East. The efficacy of 0.3 g. N.A.B. once weekly for a few weeks must be seen to be believed, since all other treatments are utterly useless. In my cases the provisional diagnosis was made on the smears obtained showing numerous pus cells and epithelial cells with complete absence of any bacteria combined with the two-glass test, both glasses showing a marked haziness due to pus. Frequency and urgency were often slight in some of my cases. Tuberculosis in my experience is never associated with a urethral discharge, especially in its early manifestations.

With regard to aetiology, I had the opportunity of having several slides stained and examined by experts in virus work, but with negative results. The similarity of some cases of early bilharzia infection and the response to an arsenical has suggested to me some submucous infection of the vesical and urethral mucous membrane. The cases of epididymitis referred to by Mr. Donovan have also in my experience showed no signs of urinary infection, the urine being crystal clear.

One last point I would like to stress is that the time has come when "urethritis," apart from the gonococcal variety, should be classified on a better basis than at present, if only to relieve the minds of our patients suffering from a persistent urethral discharge.—I am, etc.,

Orford, Woodbridge. **F. L. LYDON.**

Obituary

W. T. GORDON PUGH, M.D., F.R.C.S.

We regret to announce the death on July 22 of Dr. W. T. Gordon Pugh, Chief Medical Superintendent of Children's and Tuberculosis Services, London County Council, and formerly Medical Superintendent of Queen Mary's Hospital for Children at Carshalton.

William Thomas Gordon Pugh was born on April 9, 1872, the son of a civil servant. He was educated at the University College of Wales, and the Middlesex Hospital Medical School, where he gained an entrance scholarship, the Lyell Gold Medal and Scholarship, and the Senior Broderip Scholarship. He took the conjoint qualification of London in 1894, the M.B., B.S. in 1895, the M.D. in 1898, and the F.R.C.S.Eng. in 1935. After appointments as house-physician and house-surgeon at his own hospital he was R.M.O. at Hackney Road Children's Hospital. In 1897 he joined the fever service of the late M.A.B. at the North-Eastern Hospital, and in 1907 was promoted medical superintendent of what is now the Southern Hospital, Dartford. In 1909 he became the first medical superintendent of the newly opened Queen Mary's Hospital for Children, Carshalton, and here he found his life's work. He retired in 1937. Gordon Pugh was at one time president of the Orthopaedic Section of the Royal Society of Medicine, and he was a member of the British Orthopaedic Association. He published many reports and articles on the problems of surgical tuberculosis, and built up and sustained the reputation of Queen Mary's Hospital at Carshalton as one of the most important centres in the country for the treatment of this condition.

W. A. D. writes:

All who knew W. T. Gordon Pugh—and indeed many who did not—will be grieved at the news of his death on July 22. In his particular specialties "Pugh of Carshalton," as he was always known, had achieved international fame.

His great interest lay in the treatment and after-care of children suffering from non-pulmonary tuberculosis and in orthopaedics generally. Queen Mary's Hospital developed under his guidance into the largest children's hospital in the country. It contained 1,284 beds and gave ample opportunity for his unlimited energy. On his transfer to the service of the London County Council in 1930 he had even greater scope for his activities and was an invaluable member of many central committees, particularly that on hospital standards.

It is true to say that Gordon Pugh was beloved by all who came into contact with him—doctors, nurses, other staff, patients and their friends and relatives. His kindness, courtesy, and patience in all things were unfailing. Every year they hold an enormous children's fête at Carshalton. Whilst he was there Pugh was the life and soul of the party; and since his retirement he attended regularly these annual gatherings. At this year's—on July 30—his presence will be sorely missed. He took a great interest in the work of the school for the patients which is part of the hospital. He was the author of a popular book on nursing. He leaves a widow and two children. His son is in the medical service of the Navy, and his daughter is married to a doctor.

We regret to announce the sudden death at the age of 73 of Dr. **Edward Morris** of Donington, Lincs. He received his medical education at St. Bartholomew's Hospital and qualified L.S.A. in 1906 and M.R.C.S., L.R.C.P., a year later. After qualifying he held the posts of resident house-physician and resident house-surgeon at St. George's Hospital. He was also house-surgeon at the York Road Lying-in Hospital for Women. Dr. Morris went into general practice at Donington 36 years ago, and during this long period earned the affection and respect of a wide circle of friends and patients in the district. The son of a gentleman-farmer on the border of England and Wales, Dr. Morris had in his early days a great interest in ponies and horses, and when he first practised in Donington used to make his round on horseback. He was keen on and proficient in many branches of sport. Of his family of seven, his son, Dr. Patrick Morris, is practising in the same district.

A colleague writes the following appreciation of Dr. A. W. **Matthew**, whose obituary notice appeared in the *Journal* of July 21: On May 27 Arthur Matthew, senior anaesthetist to St. Mary's Hospital, died suddenly as he was saying good-bye to friends at the Royal National Orthopaedic Hospital. There had been no illness, no premonitory sign, no suggestion that he was not in normal good health. During the last few war years he had often complained of fatigue due to incessant work, which included a large number of night calls, but to those of us who worked with him in the theatre day after day there was no suggestion that he suffered from some mortal lesion. The news of his death came as a great shock to all who work at St. Mary's. Matthew was not only one who administered anaesthetics. He made a careful examination of all his patients before the operation, and also, by his insight into human nature, an accurate assessment of the mental and emotional state. Though the time of his association with his patients was necessarily brief, yet he came to know them and gain their confidence, which made the ordeal of operation something of a quiet, unanxious surrender. Matthew had less interest in the academic side of his work than in its practical application. He spoke and wrote little, but his merit was acknowledged by his colleagues when they elected him President of the Section of Anaesthetics of the Royal Society of Medicine in 1942. All who knew him recognized his professional merit. Those who were fortunate enough to be his friends also knew him as a great, loyal, delightful colleague and companion. The loss to St. Mary's is irreparable, not so much because we have lost a great anaesthetist as because the whole hospital, through all its ranks, has lost a lovable friend.

The Services

The President of the Czechoslovak Republic has conferred the Military Medal (1st Class) on Wing Cmdrs. J. C. Blair, R.A.F., and J. C. Scott, R.A.F.V.R., in recognition of valuable services rendered in connexion with the war.

Temp. Surg. Lieut. D. A. T. Farrar, R.N.V.R., has been mentioned in dispatches for bravery and skill, while serving in one of H.M. ships, in a successful engagement with enemy light forces.

Temp. Surg. Lieut. W. L. Leslie, R.C.N.V.R., has been mentioned in dispatches for courage, tenacity, and great devotion to duty in fire-fighting and rescue work under exceptionally hazardous conditions.

Capt. E. J. Jones, R.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant conduct in carrying out hazardous work in a very brave manner.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in Italy: Brig. (Temp.) E. M. Townsend, M.C., and Brig. (Acting) D. G. Cheyne, C.B.E., M.C., late R.A.M.C.; Cols. (Temp.) G. W. R. Bishop, O.B.E., T.D., J. M. Mackenzie, C.B.E., M.C., R. E. Rees, M.C., T.D., and J. T. Robinson; Lieut.-Cols (Temp.) T. M. R. Ahern, W. M. Capper, J. H. Croom, G. Y. Feggetter, R. T. Grant, K. McNeill, O.B.E., H. Mannington, J. S. Miller, T. P. P. Murphy, R. J. Niven, M.C., O. A. Savage, H. L. Sheehan, J. Trotter, O.B.E., R. L. Turner, O.B.E., and H. S. Ward, O.B.E.; Lieut.-Col. (Acting) H. W. L. Nichols, T.D.; Major E. Fowler; Majors (Temp.) D. W. Ashcroft, D. S. Austin, H. M. Barnard, D. Bell, H. Bridges, A. S. Bullough, W. A. Carey, H. J. Croghan, L. F. Dawes, F. H. Edwards, M.C., A. B. Evans, W. R. Everatt, H. K. Fidler, T. E. Field, M.B.E., M. C. K. Finlayson, A. M. Giles, E. H. C. Harper, L. Heasman, G. M. Hobbin, O. P. D. Lawson, W. M. Macleod, K. C. Mallen, R. J. B. McEwen, P. C. Mitchell, M.C., W. F. Nicholson, H. D. O'Brien, R. G. W. Ollerenshaw, P. L. O'Neill, J. D. O'Riordan, A. Orleck, M.B.E., D. L. Owen, M.B.E., J. H. Patterson, A. S. Ramsey, C. G. Rob, M.C., H. L. Settle, R. Thornley, R. A. R. Topping, D. J. D. Torrens, F. E. Wheeler, A. B. White, W. J. Wiles, W. Wilson, and J. Yofe; Major (Acting) P. K. Walker; Capts. J. R. Bennett, D. C. B. Bramwell, A. L. Brown, P. H. Davison, D. S. Dick, E. Greenwood, A. A. Guild, A. M. Gwynn, P. M. James, G. H. P. John, R. M. J. Keir, H. C. Kennedy, H. Levine, R. J. A. Macdonald, M.B.E., J. M. McInroy, L. C. Montgomery, H. B. Morris, H. Mowschenson, K. I. Peckitt, J. Pinching, J. J. Reeks, G. T. Robertson, A. F. Rodger, R. W. Ross, R. Shields, A. M. Stewart, G. B. Tait, V. N. Taylor, and H. D. S. Vellacott; Capts. (Temp.) J. P. Adlam, J. S. Brunton, L. Camrass, F. J. Downes, J. A. J. Hammond, H. G. McQuade, and N. C. Mond; and Lieuts. R. Frame, N. L. Loosmore, D. J. L. Rowland, and E. D. Waters, R.A.M.C. Col. (Temp.) R. L. Raymond, O.B.E.; Lieut.-Cols. (Temp.) V. D'A. Blackburn, A. N. Mackenzie, and T. K. White; Majors (Temp.) H. R. Anand, D. M. Iyer, and H. F. T. Macfetridge, D.S.O.; Capts. H. M. Archibald, S. R. N. Rao, R. Ramachandra, and S. Mukerii; and Lieuts. C. N. Le Tang and L. Siviah, I.A.M.C.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in Burma: Brig. (Temp.) H. G. Winter, M.C., late R.A.M.C.; Brig. (Acting) D. F. Panton; Cols. (Temp.) J. H. Baird (Reserve of Officers), A. O. Bekenn, O.B.E., and J. R. Dawson; Col. (Acting) S. W. K. Arundell; Lieut.-Cols. (Temp.) F. Ayrey, D. H. D. Burbridge, A. Burns, H. Gass, G. B. Heugh, A. J. Martin, T. A. Pace, J. P. Raban, J. R. Steen, D. S. Valentine, and E. J. M. Wenyon; Lieut.-Col. (Acting) S. B. Dimson; Majors (Temp.) K. D. G. Abbott, D. G. Adamson, D. M. Baker, F. I. Evans, P. B. L. Nicholas, P. J. O'Connell, G. W. Pinder, C. I. Raeburn, and G. I. M. Ross; Majors (Acting) R. M. Campbell and J. F. Stokes; Capts. B. E. Camus, S. Citron, P. J. R. Davis, J. W. Doupe, H. W. W. Good, D. R. Gunn, H. L. Hart, J. C. Henry, A. B. J. Hill, L. P. Hodgson, J. C. Jeffrey, E. L. H. Jones, J. C. Leask, J. O'Hara, N. Pedersen, M.C., H. G. Stanton, D. B. Watson, B. G. Wells, and R. B. Wright; and Capt. (Temp.) D. Blacklee, R.A.M.C. Lieut.-Cols. (Temp.) J. H. Arthur, M.B.E., G. B. Jackson, M. L. A. Dewan, J. L. O'Neill, and A. D. Wilson; Majors (Temp.) L. M. CASUALTIES IN THE MEDICAL SERVICES

Wounded.—War Subs. Capts. D. R. Hughes, L. G. Kiloh, and F. H. Leckie, M.C., R.A.M.C.

Universities and Colleges

UNIVERSITY OF OXFORD

In Convocation on July 21 the honorary degree of D.Sc. was conferred on Prof. H. M. Turnbull, D.M., F.R.S., F.R.C.P., director of the Pathological Institute of London Hospital.

UNIVERSITY OF CAMBRIDGE

The Marmaduke Sheild Scholarships in human anatomy have been awarded to David Bulmer (Peterhouse) and Rodney Peter Holmes (Trinity College).

UNIVERSITY OF LONDON

The following scholarships, exhibitions, and prizes have been awarded at University College Hospital Medical School.

Goldsmid Entrance Scholarships, Miss J. D. Cross (University College, London), V. E. Amassian (Trinity College, Cambridge). *Goldsmid Entrance Exhibition,* I. W. Broomhead (St. John's College, Cambridge). *Filliter Entrance Scholarship in Pathology,* W. I. N. Kessel (Trinity College, Cambridge). *Atchiso* [illegible] *ship,* Miss M. E. Hughes. *Magrath Scholarshi* [illegible] Wade; *Midwifery,* G. F. Jolly; *Surg* [illegible] *Erichsen Prize,* T. H. Morgan. *Li* [illegible] C. J. Don. *Alexander Bruce* [illegible] *Cold* [illegible]

(Salisbury, S. Rhodesia), Dr. Robert Alexander Miller (Grantown-on-Spey), Dr. Alexander James Murray Drennan (Edinburgh), and Dr. Wm. Forbes (Edinburgh) were elected Fellows of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on July 20, with Prof. R. W. Johnstone, President, in the chair, the following candidates, who have passed the requisite examinations, were admitted Fellows: Denis Charles Bodenham, Roy Theodore Scovel Goodchild, Thomas Labatt Lawson, Michael Lentin, Michael Joseph Murphy, John Alexander Vere Nicoll, John Archibald Simpson, John David Stenstrom, Kenneth Frank Wilsdon.

It was resolved that, to celebrate the victory in Europe, the Honorary Fellowship of the College be conferred upon the following members of the medical profession: Brig.-Gen. Elliott C. Cutler, U.S. Army Medical Service; Andrew Davidson, M.D., Chief Medical Officer, Department of Health for Scotland; Surg. Vice-Admiral Sir Sheldon F. Dudley, K.C.B., M.D., F.R.S., F.R.C.P., Medical Director-General of the Navy; Major-Gen. Paul R. Hawley, U.S. Army Medical Service; Mr. Eardley L. Holland, M.D., F.R.C.S., President, Royal College of Obstetricians and Gynaecologists; Dr. Johan Holst, Professor of Surgery in the University of Oslo; Sir Alfred Webb-Johnson, K.C.V.O., C.B.E., D.S.O., President of the Royal College of Surgeons of England; Sir Edward Mellanby, K.C.B., M.D., F.R.S., F.R.C.P., Secretary, Medical Research Council; and Air Marshal Sir Harold E. Whittingham, K.C.B., K.B.E., F.R.C.P., Director-General of Medical Services, Royal Air Force.

SOCIETY OF APOTHECARIES OF LONDON

At a recent meeting of the Court of Assistants, with the Master, Dr. J. P. Hedley, in the chair, the deaths of Sir Stanley Woodwark, Immediate Past Master, Sir Buckston Browne, Honorary Freeman and Diplomate, and Viscount Dawson of Penn, Honorary Freeman, were announced with regret.

The following were appointed to represent the Society on the bodies named: Dr. J. P. Hedley on the Central Midwives Board; Mr. L. Vernon Cargill on the Research Board for the Correlation of Medical Science and Physical Education; Surg. Rear-Admiral C. P. G. Wakeley on the British Postgraduate Medical School.

The following served on the Strickland Goodall Memorial Lecture Committee: The Master, Dr. J. P. Hedley, and Dr. Geoffrey Bourne; Prof. T. R. Elliott, nominated by the Royal Society; Dr. George Graham, nominated by the Royal College of Physicians of London; and Surg. Rear-Admiral G. Gordon-Taylor, President of the Royal Society of Medicine. Dwight Emary Harken, licentiate of the Society, was appointed as fourth lecturer and delivered a lecture entitled "Foreign Bodies in Relation to the Great Vessels and Heart" in the Hall on June 26.

Sir Wilson Jameson and Prof. W. D. Newcomb were reappointed adjudicators for the Gillson Scholarship in Pathology, which was awarded to John Llewellyn Penistan for 1945.

The follo [illegible] Master with the Livery of th

Medical News

The British Medical Association is advertising for two Assistant Secretaries as well as for a Scottish Secretary. It is allowing a four-months period to intervene between the advertisement and the last day for applications in order that Service candidates at home or over-seas shall have opportunity to apply. The Scottish Secretary will take up his duties on Jan. 1, 1946, or on demobilization, and the Assistant Secretaries on Feb. 1, 1946, or on demobilization.

Mr. Justice Macnaghten, allowing an appeal by the Crown from a decision of the Commissioners for the Special Purposes of the Income Tax Acts, on July 27 decided that the National Anti-Vivisection Society were not entitled to exemption from income tax under Section 37 (1) of the Income Tax Act, 1918.

The announcement in this column last week (p. 139) regarding the future of the Canadian military hospital on Lord Astor's estate at Cliveden was based on information now stated to be inaccurate. Negotiations are now going on about the future of the hospital and its contents, but it seems unlikely that they will terminate in an arrangement such as our statement said had been completed.

Dr. John Chancellor McKenzie, O.B.E., retired last month from the post of Commissioner of Medical Services, Ministry of Pensions, Edinburgh, and was succeeded by Dr. John Wilson McCagie. On his retirement the staff of the Ministry entertained Dr. McKenzie, and a presentation was made to him by the Chief Regional Officer.

Mr. T. E. A. Stowell, M.D., F.R.C.S., member of the Council of the Industrial Welfare Society, has been elected First Vice-president of the International Association for Life-Saving and First Aid to the Injured.

Capt. R. D. Marett Tims, L.M.S.S.A., has been appointed Officer (Brother) in the Order of the Hospital of St. John of Jerusalem (*corrected announcement*).

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* the only variations of any size were falls in measles (469) and diphtheria (36), and a rise in whooping-cough (48).

In Yorks West Riding the notifications of whooping-cough rose by 35, and of diphtheria fell by 21. In contrast to the general fall in measles, rises occurred in Essex (82) and Norfolk (51). A slight rise in measles was also recorded in the south-west, where the regional total increased by 32.

Dysentery notifications fell by 4. The chief centres of infection were London 47, Lancashire 32, Warwickshire 15, Essex 14, Middlesex 13.

In *Scotland* a general fall was reported in the incidence of infectious diseases. The largest decreases were scarlet fever [illegible]

No. 28

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 14.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Diphtheria Immunization in Asthmatic Child

Q.—*Two children, aged 7 and 9, were immunized 5 years ago with T.A.M. What would you advise as a boosting injection? One child is asthmatic. Is there any fear of undue reaction if A.P.T. is used? Would you advise combining with whooping-cough prophylactic vaccine?*

A.—Children aged 7 and 9 years should not be given a boosting dose of A.P.T. without a preliminary Schick test, to which they may give a pseudo-positive reaction indicative of an increased sensitivity to diphtheria toxoid. In such cases an injection of A.P.T., or indeed of any diphtheria antigen, may evoke a rather severe reaction. T.A.F. is often used for the immunization of older children and adults, but T.A.F. contains a small amount of a foreign protein and is therefore not to be recommended for use in an asthmatic child. If the Schick test is positive without any pseudo-reaction, a small dose (0.2 c.cm.) of A.P.T. should be used. If the test is pseudo-positive no further immunization should be attempted; instead, the Schick test should be repeated in 3 to 6 months' time, when it will often have become negative in pseudo-reactors. Immunization against pertussis in children of this age is scarcely advisable, since they are past the age of greatest susceptibility; besides, the large doses of pertussis vaccine usually recommended may produce undesirable reactions in an asthmatic child.

Sulphonamides for B. coli Infections

Q.—*Are any of the recent sulpha drugs, such as sulphamezathine, likely to prove effective against old-standing B. coli recurrent cystitis? Stock and autogenous vaccines have been tried and found useless. Mandelates after a number of courses over many years are losing their effect. Wash-outs and other urinary antiseptics have been of only temporary assistance.*

A.—It is not clear from the question whether treatment with any of the sulphonamides has yet been tried. If not, the instructions for the treatment of urinary-tract infections in *The Medical Use of Sulphonamides* (M.R.C. War Mem. No. 10) should be followed. It is almost impossible to say, without an actual *in vitro* test of the patient's own organism, which of the newer sulphonamide compounds is likely to be the most effective. Sulphathiazole is on the whole more active than sulphanilamide, and has been found to act well in quite small doses, such as 0.2 gramme 4 times a day. Sodium bicarbonate should be given in addition, in order to keep the *p*H of the urine slightly on the alkaline side of neutrality. An advantage of sulphamezathine is that owing to its greater solubility larger doses can be given without risk of crystalline deposition in the urinary tract; this drug might be tried in doses of 1 gramme 4 times a day if others fail.

Treatment of Asthma

Q.—*What is the most modern and best treatment for a patient during an asthmatic attack?*

A.—The patient should be sent to bed, preferably a bed with kapok pillows and rubber mattress and in a bedroom with as little as possible in the way of carpets, rugs, drapery, and other sources of dust. Encouragement and reassurance may greatly help the nervous patient. The physician should place his hands on the front of the chest and encourage the patient to empty the lungs, rather than strive vainly to expand them even further. An initial subcutaneous injection of 3 to 5 minims of 1 in 1,000 solution of adrenaline hydrochloride should be given. This may be repeated at half-hourly intervals, and if relief is still not obtained the syringe may be strapped in position and the adrenaline injected continuously at the rate of 1 minim a minute. Injection of adrenaline may be supplemented or replaced by inhalation of the drug; 1 in 100 solution is used for this purpose. The mouthpiece of the nebulizer is inserted in the mouth and one or two puffs are inhaled at the moment of deep inspiration. If adrenaline fails, the physician may try pituitary extract, 0.5 to 1.0 c.cm. intramuscularly; theophylline with ethylene diamine (aminophylline), 0.25 to 0.5 gramme in 10 c.cm. of water, very slowly intravenously; or pethidine hydrochloride, 100 mg. intramuscularly. It is possible that pethidine shares the disadvantages of morphine, and it should be used with care. Inhalation of oxygen, or oxygen and helium, may be of value if the attack is protracted.

In conclusion, there is nothing very modern about present-day therapy of the asthmatic paroxysm, for adrenaline has been used since the beginning of the century. The best treatment is early treatment; the longer treatment is delayed, the more likely the attack is to become prolonged and intractable. Finally, treatment should not be regarded as over when the paroxysm is relieved. It is, in fact, only just begun, and every effort must then be made to discover the factors which have excited the paroxysm and to remove or remedy them if possible.

Pituitary Extract for Herpes Zoster

Q.—*It has been stated that herpes zoster has been successfully treated by pituitary extract. Has this method of treatment been extensively tried, and with what result?*

A.—The reference in the *Extra Pharmacopoeia* (Martindale) is to a paper by S. H. Portnoy, "Some Experiences with Posterior Pituitary Solution in Herpes Zoster," published in the *J. Med. Cincinnati* (1938, **18**, 619). Files of this journal are apparently not available in this country. The treatment of herpes zoster by pituitrin was introduced by Vandel in 1923. In 1930 Sidlick (*Arch. Derm. Syph.*, Chicago, 1930, **22**, 91) reported favourable results in a series of 54 cases. The duration of the disease before treatment varied from 24 hours to 5 weeks. Many of the patients obtained relief of pain after one injection, but a number required three and one required six. There were apparently no failures, and Sidlick described the treatment as "most efficient." Niles (*N.Y. St. J. Med.*, 1932, **32**, 773) compared 16 cases of herpes zoster treated with pituitrin and an equal number of controls receiving other treatments. He concluded that the course of the illness was shortened and the severe pain usually accompanying it was generally rapidly relieved by pituitrin injections. Niles's series included one man aged 70 with post-herpetic neuralgia, and he was not relieved. Gillett, who reported in the *Lancet* (1934, **2**, 307) a group of 3 cases treated with pituitrin, concluded that it acted best when the pain was more intense, but that relief was uncertain and not infallible. The treatment is mentioned in more recent books and periodicals, but no other extensive trial has been found in the literature available.

Testosterone in Angina Pectoris

Q.—*Recent clinical trials suggest that testosterone propionate exerts a favourable effect on the symptoms, if not on the course, of angina pectoris. Is this so, and what is the scheme of dosage? What, if any, are the side-effects from the use of this drug, and is previous cardiac infarction a contraindication? One or two recent references would be appreciated.*

A.—Testosterone propionate has been used for the treatment of angina pectoris, and very favourable results have been recorded. The rationale of the treatment is by no means clear. Walker concludes that there is a direct vasodilator action, since this therapy was found by him to be effective in peripheral vascular disease. In animals testosterone produces hypertrophy of the heart muscle. It might also be argued that arterial degeneration occurs in later life when gonadal function is decreased, and that testosterone would tend to retard or reverse such effects. The dosage is 50 mg. injected intramuscularly twice or thrice weekly. There are unlikely to be any side-effects from this treatment. Recent cardiac infarction, however, should probably be regarded as a contraindication. The two references are: Walker, T. C., *J. clin. Endocrinol.*, 1942, **11**, 560; Lesser, M. A., *New Engl. J. Med.*, 1942, **226**, 51.

Fox-Fordyce Disease

Q.—*Is there any cure for Fox-Fordyce disease, and if not, what is the best remedy for the irritation?*

A.—Fox-Fordyce disease, characterized by an itchy eruption of small red or skin-coloured papules, is fortunately a rarity, because treatment often entirely fails. The primary changes are located in the apocrine glands, and therefore *x*-ray treatment may help by its selective action on them; the secondary lichenization is also beneficially affected by *x*-ray treatment.

Doctors' Expectation of Life

Q.—*What is the expectation of life of a medical man at the age of (a) 60 and (b) 65?*

A.—It is not possible to answer this question, as no life table has been compiled on the mortality of the medical profession. It is certain that the expectation of life would be less than that for all males, since the ratio of the death rate to that of all males, for ages 45–54, 55–64, 65–69, is 108, 111, 103. The standardized mortality ratio for medical men aged 20–65 is 106 and ranks in the 123rd position in a list of 200 occupations tabulated by the Registrar-General.

Splitting of Nail Edge

Q.—*What are the cause and treatment of frequent splitting of the nail edge parallel to the free border?*

A.—In a healthy person the nail grows continuously from its root at the rate of 1 mm. per week; the proximal half-inch is supported by the underlying tissues; but the extreme distal portion is unsupported and readily betrays any inherent weakness by breaking under slight trauma. Any condition which adversely affects those cells in the nail-bed which manufacture the nail-substance will lead to a weakness in the transverse section being made at that time, though it may be many weeks before that section will reach the end of the nail, where it will be more subject to trauma. A transverse ridge indicating the affected section will sometimes be seen (Beau's line).

Brittleness of the nail (onychorrhexis) may be a congenital defect, and has been known to occur in several consecutive generations. Most cases, however, are due to pathological conditions which affect the root of the nail. Any serious illness or injury may lead to the formation of a weak section of nail which will prove brittle when it reaches the termination of the nail. Constitutional disease such as gout is said to lead to the formation of brittle nails, and thyroid insufficiency may produce the same result. General skin diseases such as psoriasis, eczema, and lichen planus sometimes affect the nail and may make it brittle. In the case of ladies the repeated application of nail varnish, and its removal by solvents such as acetone, may make the nail more friable, and the same result may follow frequent washing of the hands in hot water, especially in a hot alkaline solution. Some have claimed that a deficiency of iron in the system may produce brittle nails.

Treatment depends upon the cause, which should be diagnosable after a consideration of the foregoing. If no cause can be found, the nail should be carefully and regularly trimmed, and trauma avoided. It has been recommended to paint the weak nails with collodion, but in bad cases it would probably be better to wear a protecting glove whenever possible.

Smallpox Vaccination

Q.—*Why is cowpox virus no longer used in this country for immunization against smallpox?*

A.—The use of cowpox virus in the prophylactic immunization against smallpox has been abandoned because we have a very suitable alternative agent for the purpose in vaccinia virus. Vaccinia virus is a fixed variant of smallpox virus made by adapting the latter virus to growth in the tissue of the calf. Direct variolization of the calf is usually unsuccessful, but the work of the Royal Commission on Vaccination (1889–97) showed how this could be done, and that the fixed variant of smallpox virus so produced—vaccinia virus—could be freed from contaminating bacteria kept in an active state by storage in glycerol. Glycerinated calf lymph came into general use for the purpose of vaccination against smallpox when this procedure was made compulsory in this country in 1898. Some people have assumed the identity of cowpox and vaccinia viruses, but the work of Downie has shown that although the two are closely allied they can be distinguished by serological and other means.

Frigidity in a Woman

Q.—*A young married woman since her marriage has not felt any sexual impulses, although her husband has normal relations with her. She is a sensible type of girl, very fond of him. No abnormality has been detected, although she had to have a plastic operation on the vulva performed by a specialist after her marriage. During coitus there has never been any vaginal secretion.*

A.—This is a big question, for there are so many causes of sexual frigidity, and these are sometimes obscure. We can only suggest some types.

Constitutional.—Some women are obviously more constitutionally highly sexed than others, depending largely on the endocrine secretions, and this in the absence of anything which may be called disease. If it is true that the pituitary is the initiator of sexual feeling, then one might look to the gonadotrophic secretion as the cause. The "lanky" subgonadal type is a case in point. There is the further fact, which we may regard as biological, that there are many apparently normal and happily married women who never have an orgasm, and the idea that women in general are just as highly sexed as men is, after all, probably a fallacy. They do, however, have a greater need of, and capacity for, love, since they themselves need protection whilst they protect the offspring.

Of *psychological* causes the possibility of a conditioned reflex has first to be considered. Many women, previously normally sexed, who after marriage have an incompletely ruptured hymen and suffer pain may thereafter cease to have any desire, although the cause of the pain is removed. One would like to know the reason for the operation on the vulva in this case, and whether there being "something wrong there" inhibited the free expression of libido. Another present-day cause is the relations with the husband. A woman with a previous romantic attachment to some other man may be "very fond" of her husband, but can never completely yield herself to him, as she is not fully in love with him; or she may be a mother to him. It may, however, be necessary to look for deeper and more unconscious causes. Though she is now "sensible" about sex, she may have inhibitions about sex due to early training or an infantile taboo regarding some sexual activity. Threats of punishment may lead to the inhibition of sex, producing a conscious guilt or fear of sex. Again, an early external masturbation, especially if it is continued over puberty, sometimes prevents the libido from passing into the vagina, in which case ordinary coitus will have no effect. But sometimes it may be merely a matter of posture, for we have known some women who have no sex feeling except with coitus *a posteriori*. A woman who as a child was given enemata may be so disposed; and this, after all, is the natural approach in animals. These are some of the causes of frigidity, from which it will be seen that the specific cause in any case may need sex investigation at the hands of an expert.

LETTERS, NOTES, ETC.

Speech Training

Dr. L. M. M. **Beadnell** writes: I would like to protest against the inaccuracy of the term "speech therapy" now coming into use. Shock therapy is not treatment of shock, but treatment of other conditions by means of shock; the same applies to malaria therapy, occupational therapy, etc. Surely the word intended is "speech *training*."

Spraying Enclosed Spaces

Mr. N. E. **Hickin**, Ph.D. (Bletchingley, Surrey) writes: In your issue of July 14 the question was asked, "Is paraffin or kerosene the best solvent for the spraying of enclosed spaces, such as mess-decks?"; and the answer is given that kerosene is about the most satisfactory carrier liquid for insecticides available at present. I wish to disagree most strongly with this contention. By far the best medium for conveying insecticides to enclosed spaces is water; and it would be agreed that this is even cheaper and more readily available, with even lower toxicity to man, than kerosene, and I have carried out numerous experiments on the insecticidal value of water-borne insecticides with the bed-bug and other infesting insects as the test insect. Several highly concentrated and officially recommended insecticides, such as the lethanes, are available in emulsified form which only require added water to dilute to the necessary strength for spraying, and it will be appreciated that these sprays are absolutely non-inflammable, and, so far as the bed-bug is concerned, equal in insecticidal value to the same concentration of lethane dissolved in kerosene.

⁂ We have submitted the above to the expert who gave the answer, and he writes: There are minor disadvantages in the use of water as a domestic insecticide base (effect of damp on wall-paper, etc., tendency to rust iron spray-guns) just as there are other objections to paraffin (smell and slight fire risk). But the major reason for advocating paraffin is that the majority of effective insecticides are soluble in oils and not in water. It is, of course, possible to emulsify them; but dilute emulsions are seldom stable, and there are obvious disadvantages in preparing dilutions before every use of a spray-gun. Emulsions, too, are usually more viscous and therefore more difficult to atomize. Finally, it is usually believed that kerosene has some slight insecticidal value of its own; and while it may be true that a certain insecticide applied as an emulsion is as toxic as the same concentration in kerosene solution, we know of little or no published evidence on the subject.—Ed., *B.M.J.*

Viper Antivenenes

Dr. J. E. J. **Palser** (Allen and Hanburys Ltd., London, E.2) writes: In his valuably informative paper on adder-bite in England and Wales (July 7, p. 13) Dr. C. W. Walker refers to the importance of the prognosis in view of a complete lack of all European viper antivenenes. We should like to mention that our branch at 7, Vere Street, London, W.1 (Tel. Mayfair 2216), has a stock, though very restricted, of snake-bite serum—*Sérum Antivenimeux E.R.* (Pasteur). This antivenene is prepared from horses which have been immunized against the venom of European snakes, and it is imported into this country because of its efficacy against the bite of the adder (*Vipera berus*). We supply it in vials of 10 c.cm.—i.e., one dose—at 10s. 6d. As, however, the stock is at present so limited, we should be much obliged if medical practitioners would order the serum for immediate use only, not for storage. On request, we should be pleased to send it by the quickest possible means.

BRITISH MEDICAL JOURNAL

PROBLEMS OF NAVAL WARFARE UNDER CLIMATIC EXTREMES*

BY

MACDONALD CRITCHLEY, M.D., F.R.C.P.

Senior Neurologist, King's College Hospital; Physician to Out-patients. National Hospital, Queen Square

PART II.—LECTURE I (*continued*)

CLOTHING

The story of naval clothing can be told in four chapters. At first there was little or no control of what was worn, and pressed men came aboard clad in their filthy rags, which were replaced only when eventually disintegrated. This practice naturally favoured the spread of louse-borne disease, and especially the *febris nautica*, or typhus. Next came the period of medical reform at the close of the eighteenth century, when Lind, Blane, and Trotter in turn pleaded for a regulation sea-habit. At length, from the weight of medical pressure, it was made compulsory for all new entries to be stripped, scrubbed—their rags destroyed—and then re-clad in clean apparel supplied by Admiralty "slop ships." Since 1789, thanks to Middleton, the comptroller, special ships were set aside to accommodate new entries during the first few weeks of their Service career. The third chapter concerns the regularization of the quantity, cut, and pattern of the clothing issued—the story of naval uniform, in fact. Two factors brought this about: the institution of continuous service in 1852, and the Grog Committee of 1857, checking the practice of men going ashore and bartering their kit for rum. The Uniform Committee of 1858 followed the precedent of the French marine of two years before, and enacted that every seaman should have so many articles of naval dress, of standard quality and appearance. The Uniform Committee of 1890 reopened the subject and made more recommendations along the same lines. This stage of preoccupation with uniform design, badges of rank, buttons, and gold lace lasted until the outbreak of the present war.

Since 1939 we have embarked upon the fourth chapter, which deals with the organized science of clothing as a means of protection against climate, flash, bullets, insects, gas, and other nocuous influences. This novel subject of clothing physiology may be considered in greater detail.

Clothing for Cold Climates

In the Royal Navy special expeditions must have always demanded special clothing, and indeed the Service has for long played an important part in advising upon the appropriate dress for polar explorers. Their counsel must have largely been empirical, founded upon the experiences of generations of explorers and the usages of local inhabitants. The need for special cold-weather clothing in the Navy would seem obvious, and yet, judging by the complaints lodged by Blane and others, no adequate routine provision was made in the old days for the exigencies of the climate. Even as late as 1890 evidence was presented to the Uniform Committee that all was not well, for we read: "*It is often quite pitiable to see the men . . . although they have piled on so many articles of clothing under their serge frocks that they can hardly move, crouching under the lee of funnel-casing, etc., shivering and shaking all over. . . . The want of giving due importance to this subject has resulted, there can be no doubt, in our men being old and rheumatic when they ought to be in full vigour. . . . Had protective clothing been compulsory and not optional, the spectacle of men spending their leave on a bed of sickness would not have been such a commonplace.*"

The Arctic operations of this war have focused attention upon this problem and have also led to a vast improvement in the nature of the clothing issued. The Canadian cold-weather-clothing trials held during the winter of 1943–4 form a landmark in this study, and gave an opportunity for a field test of the comparative merits of the Navy, Army, and Air Force clothing used by the British, Canadians, and Americans.

Field tests show that cold-weather clothing must be flexible enough to suit a number of different circumstances. There are problems of dry cold *versus* wet cold; still air as opposed to high-velocity winds; sudden rises of temperature which, though occurring in the lower part of the scale, are as great a contrast as between a spring morning at home and a tropical midday. Lastly, there are the differences between men engaged in heavy work and those who stand inactive on look-out; and an important intermediate group whose exertions are interrupted by short stand-easies in the open.

The role of cold-weather clothing is one of heat regulation: it forms a protective insulation which retards heat exchange. This is brought about in various ways—partly by the thermal properties of the fabric itself, partly by bodily heat production caused by the heavy clothing, but mainly by the garments trapping insulating layers of warm air—the so-called "private climate." When clothes become wet, either from sweating or from outside, the insulatory action suffers enormously, for water has 240 times the thermal conductivity of air and 3,000 times its heat capacity.

A. P. Gagge, A. C. Burton, and H. C. Bazett have made an ingenious attempt to form a scientific vocabulary for discussing the thermo-regulatory function of clothing. They start by assuming that the sensation of environmental comfort depends upon the temperature of the skin, as suggested by the traditional table drawn up by Vincent. It is, of course, open to question whether this is not an over-simplification of the problem, by ignoring cortical mechanisms which participate in the feelings of warmth and of cold. Nevertheless, it may perhaps serve as a working hypothesis. They suggest that the optimal average skin temperature conducive to comfort is 92° F. (33° C.). A person seated at rest and in a state of thermal comfort has a metabolic activity of 50 calories per hour per square metre of the surface area. This unit they call a "*met.*" For a man of average size this is about the same thermal output as that of a 100-watt lamp. The same individual when standing has a heat production of 1.5 met (or 75 cal./m.^{2}/hr.), and walking fast on the level, 4 met (or 200 cal./m.^{2}/hr.). The amount of insulation (as afforded by clothing) required to keep such a sitting-resting subject comfortable in a normally ventilated room (air movement 20 ft./min. at a temperature of 70° F. (21° C.) and a humidity less than 50%) constitutes the unit measurement of insulation, which they call a "*clo.*" One clo equals the insulating value of everyday clothing, or the value of a heavy top-coat alone. In cold environments the additional clothing needed to maintain comfort may be reckoned in terms of 2 clo, 3 clo, and so on.

---

* Being the Croonian Lectures delivered to the Royal College of Physicians, July 10 and 12, 1945.

Doriot says that 4 clo is the greatest thickness of clothing in which a soldier can work; and 8 clo is the maximum he can carry as sleeping-gear.

The conception of a clo unit is attractive by its very simplicity. It recalls the traditional Chinese description of cold weather in terms of a "one-coat" or a "two-coat" day. Perhaps it is too simple, and may vary and err like other biological measurements based on subjective sensations translated into speech. The factor of acclimatization is not catered for. For greater accuracy one must resort to the physical laboratory and compute the insulation values of a particular textile from the density, thickness, and thermal conductivity of the fabric.

Among the physical properties of clothing which matter in heat regulation there is the density of the textile, the looseness of the weave, the thermal conductivity, and the hygroscopic value of the fibres. These properties affect the permeability of the cloth to air, to water, and to water vapour, and its power of heat storage. Fabrics which are hygroscopic—e.g., wool, silk, rayon—are thereby minor sources of heat until equilibrium is reached between the garment, the body, and the environment. The age of a garment, its cleanliness, and its reaction to repeated wetting or washing, all affect thermal conductivity. Colour has a bearing upon the heat-absorbing powers. Consequently the value of a particular material as a protection against cold is influenced by a number of factors. For example, Siple has compared blanket cloth (15.1 oz.) with melton overcoating (22.8 oz.): though the former is 30% lighter than the latter it has 1.4 times more insulation value. But as it is 4 times more permeable to air its protection in moving air is low. If, however, a layer of poplin (8.9 oz.) is put outside the blanket the weight now becomes the same as the overcoating. In still air its insulation value is now double that of the overcoat material, while in moving air its resistance is nearly 3.75 times as great.

As a means of protection against cooling by radiation and conduction wool is both efficient and economical. Protection against cooling by moving air calls for a shell of a closely woven, light-weight, water-repellent cotton fabric—e.g., those known eponymously as Wordie, Grenfell, Fison, Byrd, or Shirley cloths.

Fur is the characteristic wear in polar climates. Eskimos use only two garments—the inner one of caribou with the hairs towards the skin, and the outer one with the hairs directed externally. Fur comprises in volume only 2% solid matter and 98% air. Its biophysical effects are analogous to wool and poplin juxtaposed, in that an insulating layer of warm air is imprisoned within the hairs while a wind-impermeable layer is formed by the hide. But for general purposes fur is much too heavy, and its scarcity would in any case preclude its use in the Service.

For those who must do hard physical work in environments of intense cold, and especially if intervals of inactivity recur, the Brynje (or Brun) system of clothing has much in its favour. It is the traditional clothing of the Norwegian ski-troops. The Brynje set of garments consists of a loosely woven string vest worn beneath a wind-proof jacket with wide sleeves, a zip-fastener opening, and a hood. Sometimes a lining of fine-mesh fishing-net is worn beneath trousers made of the same wind-proof material as the tunic. Mittens and a képi type of cap, also lined with fishing-net, complete the outfit. It is important that this system of clothing be adopted in its entirety, for there is no special virtue in wearing Brynje vests as compared with any other loose-meshed undergarment without the rest of the outfit. So long as the wearer is exerting himself and producing heat the hood is lowered and the zip-fastener undone. When at a standstill the hood should be raised and the tunic fastened tightly to the neck.

The advantages of such a system of clothing might be considerable in the case of naval landing parties and of Royal Marines operating ashore. The Brynje system is not likely to be of much value to personnel afloat, except perhaps the stoke branch.

It is believed that at −40° F. in still air 11 clo of insulation is required to conserve body heat. Watch-keepers in severe Arctic weather will therefore need a different system of clothing. The Navy has adopted and modernized the pattern of the anarak, or the traditional Eskimo garment. This comprises a long smock of duffel cloth furnished with a hood and covered with a layer of windproof material—e.g., Grenfell cloth. Long-haired fur—wolverine or musk-rat—edges the hood. Trousers of wind-proof fabric are worn over the ordinary serge trousers. Such a garment is especially useful in conditions of dry intense cold, and perhaps less suitable for the driving wind and wet of a North Atlantic gale. For this latter type of weather a one-piece suit would be desirable. One of the chief difficulties about winter clothing in ships is that bulkiness makes it difficult to clamber through hatchways. The same applies to tank crews operating in severe cold. There is a scope, therefore, for a one- or two-piece padded (or wadded) suit like the winter garments of the Chinese or Russians, but made of modern closely woven fabric, lined with a light-weight heat-insulating flock—e.g., kapok, aerogel, or bubbfil. Most difficulty is found in the choice of protection for the hands and feet. For walking through crisp snow there is much to be said for the Russian "valinki," or high boots of felt. Unfortunately they are unsuitable in the wet even when covered by a rubber galosh; hence their value in the Royal Navy is limited. Ordinary rubber and leather sea-boots are most inadequate in very cold weather. The foot-gear worn by Arctic dwellers is much better—e.g., moccasins, mukluks, finneskos, and kamliks. The last, made of untanned sealskin with the hair close-shorn and sewn with reindeer tendon, are almost ideal, though for shipboard wear they need wooden or leather soles. Kamliks are already in limited use in the Service, and were the supply problem simpler they might now be in general issue. The choice of gloves turns on the question whether the rating is called upon to carry out finger manipulations or not. If so, there is much to recommend a glove made of rayon or silk, worn beneath a fur mitt. According to Doriot, 2 clo is the most that can be worn on the hands and dexterity still be retained. Otherwise a duffel cloth mitt covered by a loosely fitting seal-leather outer one is most suitable. Separate "trigger-finger" compartments are not approved.

Eskimos make considerable use of the insulating properties of dry "senne-grass," which they stuff inside their gloves, boots, and pockets. This practice might be adopted and improved upon by using a more efficient light-weight plastic.

Electrically heated suits, as used in the R.A.F., have been seriously considered for naval wear. Watch-keepers in exposed positions, unable to move about to keep warm and too cramped to wear many layers of clothing, might be made comfortable and more efficient by such means. Director crews in the control tops, and perhaps look-outs upon an open bridge, are in mind. The various technical difficulties are not insurmountable. To the physiologist one of the problems concerns the correct placing of the heating elements within the suit—whether to warm the trunk, the extremities, or both. Overheating must be avoided, lest the wearer become somnolent.

Clothing in the Tropics

Let us now turn from Arctic to tropical clothing. In this connexion nothing is more striking than the contrast between the practice a generation or so ago and that which obtains to-day in ships on tropical service. During Victorian times, and even within the memory of many serving officers, it was usual in the Persian Gulf in the hottest season to wear high-necked uniform, thick underwear, topees, and spine-pads. The ratings' white ducks were heavy, cumbersome, and uncomfortable. Disciplinary action was taken against those who ventured on deck without sun-helmets. "*The best dress in a hot climate, for working, and in boats is a check shirt with collar over a flannel*": so wrote Admiral Commerell in 1889.

Admiralty Fleet Orders, and especially those issued from the East India Station, display the gradually changing opinion about correct tropical wear. In 1871, we read, officers must wear waistcoats if they elect to leave their frock-coats unbuttoned. We find that in 1893 the signal might be made in hot weather, "Off jumpers." In 1912 singlets instead of flannels were permitted on occasion in the Persian Gulf. In 1921 the sennet hat (i.e., the characteristic sailors' straw hat) was abolished. In 1925 shirts were allowed instead of tunics, and, at the discretion of the senior officer, ratings—but not duty men—might be excused jumpers. In 1932 officers' tropical rig comprised tunic, shorts, and black stockings.

To-day ratings afloat in the Tropics wear shorts and sandals, and usually nothing else, even on their heads. Officers may wear the same. In boiler-rooms, of course, light clothing is worn to protect the skin against the intense radiation of heat. Ashore, officers and ratings wear, as "tropical rig," cap, shirt, shorts, white stockings, and shoes. Sun-helmets and dark glasses are virtually never seen, and the spine-pad, which survived as an extra strip of material sewn into the rating's shirt, has gone by the board. Contrary to all prognostications, the health of the Navy has improved since this scanty rig became the custom, especially as regards prickly heat and boils.

What is the reason for such a change from overdress to comparative nudity? In the first place it is largely sociological. Sailors nowadays share with the rest of the community a high standard of living and of personal hygiene. Scanty comfortable wear is now a hall-mark of emancipation, social security, and enlightenment. In part, overdress in the Tropics was bound up with the idea of protection against chill and the "dry belly-ache." The high incidence of fever in the eighteenth-century Navy was at times ascribed to a drop in temperature after sundown, but it is obvious that unrecognized cases of malaria were chiefly at work. To protect against the perils of the miasmata, flannels and woollens were worn in the Tropics, especially by boat crews at night. Traces of this belief linger in the cult of the cholera belt as a protection against tropical infective enteritis.

Some of the blame must be laid on the naval executive, and on Admiral Lord St. Vincent in particular. Like many other high-ranking laymen, he held strong but peculiar views on medical matters. In a Fleet Order of Oct. 13, 1810, we read: "*Confident as the Commander-in-Chief is that many consumptive cases might be prevented and others mitigated by timely application of flannel next the skin in catarrhs, coughs, and common colds, he most seriously exhorts the captains of ships comprising the fleet under his command to inculcate this doctrine in the minds of their surgeons, who, from caprice and passive opposition to, every wholesome regulation, grossly neglect this important duty.*" Naval medicine suffered as the result of this lay interference; for the surgeons—startled into acquiescence—fell into line, and for a time actually became the chief exponents of this cult.

Thus, during the Committee stage of the 1890 Commission on Clothing, opinions were sought as to the most suitable rig for the Tropics. The staff surgeon in *H.M.S. Hercules* testified that "*cholera belts made of two thicknesses of best flannel, overlapping in front, and secured by strings, and well quilted; . . . would in my opinion prevent an enormous amount of diarrhoea, enteritis, and even dysentery . . . inboard ship, especially in the Tropics.*" Another offender was the then Medical Director-General, whose *ex-cathedra* recommendations for the Tropics comprised: flannel with sleeves reaching half-way to the wrists, and flannel underpants coming below the knee in order to protect the joints against rheumatism; and a modified sun-helmet on all occasions, to protect the nape of the neck—"a vital part of the nervous system."

The scanty dress worn nowadays at sea appears ideal from physiological and hygienic points of view, but there is a drawback—namely, the risk of severe burns during enemy action. There is a need, therefore, for some sort of garment which will cover all exposed areas of skin, including face and hands; in other words, an action rig which can be quickly donned when needed. This rig should be of the lightest possible weight, so as to impose the least physical load; it can, if necessary, be made of material impregnated against flash. The choice of fabric is a wide one, and there is much in favour of a loose cellular-weave cotton, so long as it is not worn ashore after nightfall. Of greater difficulty is the decision as to the appropriate design, and trials have been made of one-piece garments; shorts which can be lengthened to form trousers; and shirts, gauntlets, and hoods stowed close at hand to the ratings' action stations. Common sense enjoins that a certain risk must be run, for it would be intolerable to wear an action rig all day and every day at sea in the Tropics, whatever its virtues against flash.

But, in addition to this working dress which can be quickly transformed into an action rig, the sailor in the Tropics will need a shore-going uniform which is smart and cool. It might be required that such a uniform be worn by landing parties and sailors on combined operations. Here the chief consideration is not flash- but mosquito-permeability. The sailor who remains ashore after sundown, or whose ship ties up in a malarious district, requires that his uniform should not expose an undue area of skin, and that the textile should be impervious to mosquitoes. This is a property which can be readily tested in the laboratory. The cool cellular weaves are thereby ruled out. Thick twills are uncomfortably hot. The fabric of choice is therefore one of the tightly woven cottons, such as gaberdine, Byrd cloth, poplin, Shirley cloth, or else nylon or a nylon mixture. Here other but less important factors will decide—e.g., water repellency, ventility, ease of impregnation with anti-gas chemicals or insect repellents, colour, durability, tropic-proofness, and lastly, of course, availability.

With personnel working and fighting ashore, and especially in the jungle, lightness of weight assumes added importance. Jungle clothing, though primarily a military problem, also concerns Royal Marine detachments. Every ounce of unessential equipment, and any undue heaviness in uniform and accoutrement, increases the physiological burden. Considerable attention has therefore been given to the determination of the relative climatic efficiency of fabrics by studying their influence on "the index of physiological effect" (Robinson). Subjects are tested in a hot chamber of standard temperature and humidity, and walk for a specified time upon a treadmill working at a certain speed. The reactions of the subject as shown by pulse rate, skin and rectal temperatures, and rate of sweating are recorded under basic conditions—i.e., while wearing shorts and shoes only. The subjects are then studied while wearing experimental uniforms of different textiles. This affords a delicate measure of a fabric's suitability for tropical wear, and in general terms it can be said that the physiological load of a material varies directly with its weight.

In the case of seamen and mariners working ashore in the Far East it is highly important so to design the working rig that not only mosquitoes but also leeches, ticks, and mites are excluded. Because of their insinuative properties this is not an easy matter, but the control of such a military hazard as scrub typhus is largely bound up with adequate covering of the trunk and extremities, together with the use of repellents.

The colour of the garment is of some importance in the Tropics, especially when the sun's glare is intense. At one time the suggestion was made that the ideal tropical dress would comprise a white outer layer worn over black under-garments. But whites, though cool and smart in appearance, need frequent laundering. They may also render the wearer when ashore conspicuous to hostile aircraft. Hence the advantages of a blue-grey uniform, which is both light enough to be fairly heat-repellent and dark enough for purposes of camouflage.

Brynje vests of wool mixtures have been tested in the Tropics. They should be worn beneath another garment, and hence add to the physiological load of the wearer. These vests have two advantages, however: they keep the outer layers of clothing off the skin, so that clammy garments do not stick to it, while mosquito-bites are also thus avoided. Brynje vests are useful for wear beneath an officer's white tunic.

It is not suggested that physiological tests should be the sole criterion in the choice of fabrics. Suitability depends upon many additional factors. A particular textile might seem ideal for tropical wear, being insect-proof and cool, and yet prove to be uncomfortable, too flat and smooth, clammy and clinging when wet, friable, and subject to deterioration from moulds. Light weight is not the only source of coolness. For instance, a loose fit combined with a certain rigidity may be an advantage in creating a wider air space. The bellows action of a pair of slightly starched shorts may give a cooling effect beyond that due to weight alone. Even the "feel" of a textile is significant. Design is most important, and constriction of the body and limbs must be avoided not only in Arctic wear (to promote free circulation) but also in the Tropics (to avoid prickly heat).

The procedure in choosing an item of Service clothing for the Tropics, jungle, or Arctic should be something as follows: First a report as to the merits and demerits of the items at present in use. Next, the selection of textiles and design which are promising and which are available in bulk. These are made up. Some go to the physiologists for testing as to heat load, insulation value, flash-proofness, and so on. Next come mock field trials, whereby troops in this country wear the items under conditions which mimic to some extent the terrain or environment which will be encountered abroad. Full reports are made. At the same time samples are dispatched over-seas for testing under genuine Service conditions. Questionaries are compiled, and reports submitted by observers sent out specifically. Lastly, after a period of, say, six months, the experimental items are returned, and examined as to wear and tear, deterioration, and so on. Such is the modern and common-sense drill which replaces the fortuitous choice of Service uniform of earlier times.

LECTURE II

The Human Problem in Naval Warfare

The first lecture mainly concerned the material side of naval warfare under climatic extremes and those modifications of environment and dress which have been evolved to meet the contingencies. One now turns to the human side of the problem, a consideration often neglected. As the Fleet developed from sail, the personnel changed from simple men engaged upon simple tasks to a community of skilled technicians and specialists. Instruments and equipment became more and more elaborate and sensitive, and mechanical and engineering research was lavished upon their design, their upkeep, and their protection against rough usage. Perhaps attention was focused too narrowly upon the instrument and not enough upon the man, who, after all, may prove to be the weakest link in the chain of efficient function. There is nothing new in this discrepancy, for it has been a perpetual source of contention in the Service. Over 150 years ago Blane was grumbling that "*sailors . . . had not the attention paid to them which would have been due even to inanimate machines of equal utility, for there seemed to be much more anxiety about preserving arms from rusting and cordage from rotting than about maintaining men in an effective state of health.*"

Two questions may be asked: first, How do men fare who have to keep watch while exposed to intense cold or excessive heat?; and, secondly, How do personnel react after prolonged service in polar or tropical climates? The one largely deals with mental and physical efficiency and the other mainly concerns morale.

On the bridge or weather-deck, or in the control top of a ship in the Arctic, a watch-keeper may remain immobilized up to four hours, unable to keep warm by exercise. During this time he is required to keep alert at some responsible, if not vital, task, the temperature being well below zero. Impeded by many layers of clothing, he faces a wind of high velocity with driving sleet or snow. Gradually the bulky clothing proves tiring and burdensome. The high wind makes hearing difficult and handicaps intercommunication. Lacrimation and smarting of the eyes impair visual acuity. The northern twilight and the mist may combine with fatigue to produce visual illusions, so that a look-out may mistake a breaking top for a bow wave or the wake of a periscope. The pain of the intense cold produces a general sensation of distress, which, as it continues, more and more dominates consciousness. In this way attention becomes distracted; the victim becomes slow and inaccurate in perception and performance. A mood of depression may supervene, though irritability is the commonest effect. Finger movements become clumsy, either through numbness from cold or because of the cumbersome Arctic handwear. Lastly, somnolence is common, and may become overwhelming when the rating comes off watch and goes below to his warm mess-deck.

The contrasting picture is that of a rating in the Tropics, trying to maintain vigilance while crouched in some minute compartment, with a dry bulb standing at 95° F. (I have known it to be 110° F.) and a wet bulb at 85° F. There may possibly be some near-by electrical apparatus which itself is generating heat to the figure of some 1 to 1.5 kilowatts, which is almost equivalent to the amount of heat that would be given off by 15 men at rest. He may be naked except for shorts; his body is streaming with sweat, and in addition he is probably covered with the irritating rash of prickly heat, perhaps secondarily infected. Hot nights—precluding regular sound sleep—diarrhoea, toe-rot, otitis externa, and other maladies and discomforts have perhaps already left their mark, and he has to cope with an exacting, boring, but highly important task.

One may quote the description afforded us by Burdon, the medical officer of a Persian Gulf sloop:

> "In addition to monotony and strain, the fierce climate played a major part in producing neuroses. The summers of 1940 and 1941 were very humid and hot, with malaria in addition in 1941. In June, 1941, for example, the forenoon temperature in the sick-bay was about 110° F., although the deck above was wooden and kept wet. Sometimes it was midnight before the thermometer registered less than 100° F. The evening fall of temperature was offset by the relative increase in humidity, so that the only respite from sweating profusely came between midnight and morning. Even so, it was usual to wake up on a mattress sodden with sweat. . . . The wet bulb in the shade on deck showed maximum recordings of just over 100° F. on three occasions. It is usually regarded as impossible to work under these conditions, but work went on for weeks on end until the cooler weather arrived. The usual rig was a pair of shorts and sandals, and these were permanently wet where they touched the body. Sweat dripped from the elbows, fingers, nose, and chin, and ran in a rivulet down the spine. It was a difficult task to write a letter without smudging it. A copious fluid intake was of course a necessity, and everyone suffered from sweat rashes, often with sepsis. A journal referring to this period mentions the 'repeated and powerful mental irritation induced by humidity, heat, and flies.' Such conditions engendered in most subjects an irritable despair, which cannot adequately be described. . . . Nearly everybody lost weight, some as much as a stone. Physical illness was common, and during the worst period as many as 10% of the complement were off duty sick at one time. In the worst quarter 43% of the total complement had an illness lasting on an average 7 to 14 days. The main causes were malaria, septic infections, and heat exhaustion; all were related to the climate. Accident-proneness was also raised during the hot weather. . . . Mood was worst when the climate was worst."

To justify drastic improvement in habitability it is not enough merely to assert that inefficiency occurs; it must be demonstrated, measured, and, if possible, correlated with the thermometer scale. The problem must be put on the very firmest scientific basis. Three approaches are open: (1) a comparison with experiences in industry; (2) field studies—i.e., in ships; and (3) laboratory tests in environments of severe cold or heat.

Habitability: Comparison with Experiences in Industry

Industrial data are to some extent tied up with experimental studies. Comparisons are hindered by the non-uniformity of the environmental standards adopted. (i) Using *dry-bulb* readings, Huntington found the optimum temperature for factory workers to be 60 to 65° F. Bedford found that 15% more work is done at 68° than at 75° F. Cadman said that work in coal-mines was impossible at a saturated temperature of 86° F. McConnell, Houghton, and Taylor asserted that a saturated temperature of 90° was the upper limit for a man at rest, but Dreosti found that fit and acclimatized persons could do light work even at a saturated temperature of 95° F.—though he did not mention how long or how well they worked. (ii) Judging by isolated *wet-bulb* figures, Wyatt noted a falling off in the output of cotton-weavers above 73° F. The Cotton Cloth Factories Regulations (1929) required that artificial humidification must cease when the wet-bulb temperature exceeded 72.5° F., and enacted that all work must stop should the wet-bulb temperature be above 80° F. Caplan found that working efficiency dropped rapidly in gold-mines over 92° F. and that it virtually ceased at 97° F. (iii) Using the terminology of "*effective temperature*" Vernon and Bedford found a decreasing output in coal-mines as the figure exceeded 66° F. According to Yaglou, twice as much work was done at 70 as at 93°, and Liberson and Marques found the work capacity halved in changing from 91 to 97°. At 95° (Yaglou) mechanical efficiency suffered, especially for heavy work. (iv) Employing *dry- and wet-bulb katathermometry*, Orenstein and Ireland noted impaired efficiency in the Rand gold-mines when the cooling power was less than 6 (dry) or 16 (wet). At cooling powers of 1.5 and 5 respectively the production was only 55%. (v) *Air-conditioning* of offices has been noted many times as leading to better performance, but the enhanced efficiency has rarely been measured. Workmen building the Boulder Dam suffered severely from heat during the first year, with 15 deaths from heat-stroke. Next year, when their dormitories were air-conditioned, there was a marked improvement, with no deaths and only 5 cases of cramp. The output of a factory in Manila was increased by 28% by air-conditioning. (vi) Lastly, *increased air movement* has been shown to give results. In the gold-mines a small fan giving 2,000 cu. ft./min., placed 10 to 20 feet away, increased output by 46%. (Orenstein and Ireland). Lee, Reid, and others showed that the physical well-being of tank crews in the Tropics was improved by spot-cooling with ambient air, and more particularly with cooled air; and still further when air—especially cooled air—was introduced beneath the clothing by means of a hose. These industrial studies have the drawbacks of intangibility, the terms "light work" and "heavy work" not being always clearly defined, details of clothing and water consumption not being given, and environmental standards being ill established. The other defect is a paucity of data as to work in cold conditions. Indeed, almost the sole available information relates to an increased accident rate in munition workers in the last war, when their factories were kept at a low temperature. This was ascribed largely to loss of manual dexterity. Moreover, there is very little information as to mental work. Almost the only information comes from Huntington, who found that the scholastic performance of U.S. naval and military cadets was lowest during both the hottest and the coldest seasons, and highest in the spring and autumn. Kuno noted that mental work was especially tiring in very hot atmospheres—an observation which he ascribed to the known inhibitory effect of mental exertion on the sweating produced by high temperatures.

Field Studies (Ships)

That inefficiency occurs at sea in all these foregoing uncomfortable circumstances can scarcely be doubted, though to demonstrate the point may not be easy. It may be that in the excitement of action the shackles of apathy and lassitude are thrown off and performance returns to normal. The same temporary improvement may happen in a laboratory when a subject is given an actual psychometric task.

Wireless sending and receiving would be a good index of efficiency, for any deterioration would soon become obvious. Thus in transmitting messages the speed of sending might drop. More errors and corrupt signals might be expected to creep in, with a tendency to lengthen the dashes and to accentuate the dots. Wireless receivers would perhaps betray their inefficiency by their posture, their untidy penmanship, and a tendency to miss the first few words of the signal.

Engine-room ratings are noticed to be sleepy and lackadaisical in very hot weather, and when off watch they turn in rather than read, write, or play cards. In submarines, before the introduction of coolers, personnel sometimes made silly errors and omissions. Two medical officers taking records in a hot and stuffy shell-handing room found difficulty in making correct arithmetical calculations. The ship surgeon may find it difficult to embark on the writing-up of his quarterly report.

In the gunnery division there may be a premature flattening out, if not a decline, in the learning or working-up curve, which usually ascends steadily after a ship has commissioned. Men engaged in heavy tasks may flag in the heat to the extent of retarding the work of others. It may be necessary to open the hatches periodically while at action stations, and to detail hands to stand by to close them in an emergency. While ammunitioning ship minor accidents are not uncommon, and these occur more often in the Tropics.

The foregoing field observations relate to tropical conditions, but would largely apply also to the Arctic. Extremes of temperature produce psychological effects which are comparable, both being in great part due to the distracting influence of intense discomfort. In the cold the greatest effects would be on personnel who are immobilized and who are on the alert to pick up a chance visual or auditory stimulus (asdic, radar, look-out personnel). Men whose work entails physical exertion—e.g., shell-handers, stokers—will suffer far less than in the Tropics. H. G. Armstrong has described the sequence of events in airmen. Restlessness, discomfort, impaired tactile acuity, numbness, and clumsiness of movement are accompanied by distracted attention, mental distress, loss of morale, indifference, or distaste towards the operational mission, leading to a tendency to panic. Stupor and death would supervene in those extreme circumstances. M. C. Grow describes the mental symptoms of exposure to cold as beginning with disordered judgment, a distortion of the intellect, leading to incoherence, confusion, and eventually to a fatal coma. The author believes the cerebral symptoms in states of cold are due to anoxia, and not to the release of histamine-like toxins into the blood.

Laboratory Tests

To gather scientific evidence it has been necessary to carry out efficiency tests under laboratory conditions. Within a hot-chamber, wherein high levels of temperature can be attained, one studies the physiological reactions of naval ratings upon a treadmill adjusted so that their work reproduces the energy expended in any of their duties afloat. But nowadays most sailors might be classed as sedentary workers, and their jobs are skilled psychomotor and psychosensory activities rather than hard muscular work. Hence one installs in the hot room mock-up instruments which duplicate the principles of ordinary naval tasks in such a way that speed and accuracy can be recorded and inattentiveness and irritability noted. Such experiments are under way in the Department of Experimental Psychology, Cambridge, and will be carried out in a naval establishment in the Tropics; while the U.S. Navy are working along similar lines at Bethesda.

Again it is noteworthy that there is a dearth of experimental psychological study of performance in environments of severe cold.

It is not intended to deal here with the physiological effects of heavy work in hot atmospheres—a subject so thoroughly studied by workers in Boston, Philadelphia, Brisbane, Johannesburg, and the University of Indiana. For the Royal Navy there is the important work under way at the National Hospital, Queen Square, by Carmichael, McArdle, Weiner, and others. My own interests lie more in the researches into psychological efficiency of ratings under various test conditions. Examination first under average temperate environments measures the inefficiency due to fatigue, and determines the effect of correct seating, lighting, instrument display, and the influence of such factors as rest, water, salt, food, and such drugs as benzedrine and pregneninolone. The optimal duration of watches and tricks—a question hitherto treated empirically—can now be answered scientifically. Such experiments are then repeated in hot rooms where the effective temperature can be regulated and maintained as desired. The subjects can be kept continuously in these hot atmospheres, for a week or two if desired.

It is not yet permissible to describe the researches of the Cambridge school. The work of Prof. F. C. Bartlett and of the late Dr. Craik, Mackworth, and Cameron will not be revealed until the war ends, but already important Service applications have emerged. Some interim data may be quoted without indiscretion. Bartlett's study of fatigue accruing from elaborate and highly skilled work can serve as an index of what probably occurs in hot environments. He points out that there may be a progressive and unnoticed raising of the threshold range, an increasing inaccuracy of timed response, a dissociation of performance and of stimulus units. The subject's insight grows more and more defective. He becomes worried, irritable, and obsessed with his physical discomfort. "He is at once more optimistic about his performance and pessimistic about his state."

This unawareness of inefficiency is of extreme importance in naval warfare. Officers and ratings, without realizing it, may be losing efficiency and yet scorn the suggestion. Physiologists will recognize a similar unconscious impairment of performance both in states of anoxaemia and in CO_2 poisoning.

Efficiency in an individual may matter little, but when that person is a vital link in a chain then the small error may become highly significant. True, one can rouse oneself from the apathy engendered by heat to give an ultimate performance which may be adequate. But such a recourse to reserve capital cannot go on indefinitely, and toleration might lead to a dangerous complacency. The personal loss of efficiency during fatigue may be projected, and, as Bartlett showed, the individual may blame the instrument rather than himself. This process of exterojection may ultimately lead to a lack of the man's confidence in his machine, an increasing preoccupation with his physical discomfort, discontent, and eventually an impaired morale.

(These lectures will be concluded in next week's issue, which will contain a list of references.)

A CRITICISM OF THE BASSINI OPERATION AND ITS MODIFICATIONS

BY

GEORGE B. MAIR, M.D., F.R.F.P.S., F.R.C.S.Ed.

Surgical Registrar, Woodend-Oldmill Emergency Hospitals, Aberdeen

In 1883 Bassini published the description of his operation for the repair of inguinal hernia. It constituted a real advance in the surgical treatment of hernia at that time, and has since been in common practice. During the past 20 years many have inquired into the rationale and results of the operation, and there has been a tendency on the part of more and more people to criticize it adversely.

A school of thought has arisen following upon the work of Hamilton Russell (1906, 1922, 1925; Ogilvie, 1937) which teaches that, for those cases of indirect inguinal hernia in which the sac is congenital, the muscles of the canal powerful, and the muscular rings competent, it is better to perform a modified operation consisting of simple herniotomy and with as little disturbance to the integrity of the canal as possible. Where there is an indication for repair, preference is given to fascial sutures or a fascial graft. The exponents of this school of thought condemn the Bassini operation, and their views contrast strangely with those of many reputable surgeons who find it satisfactory. The exchange of correspondence in recent issues of the *Journal* has raised the old question of hernia repair again, and has prompted me to write this paper, in which the Bassini operation is discussed on the basis of the experiences of many workers that have been published during the past 62 years. The operation is here considered from the point of view of theoretical soundness and practical results. The statistics given have been taken from papers in which the authors' claims as to recurrence rates appear to be accurate, follow-up of the cases has been carried out, and the criteria of cure have been exacting.

In a paper published by Randall (1930), Deaver, professor of surgery, University of Pennsylvania; Harvey, chief surgeon in New Haven (Connecticut) Hospital; McGuire, professor of surgery, Vanderbilt University, Nashville, Tennessee; Phemster, professor of surgery, University of Chicago; White, surgeon to Washington University, Washington, D.C.; and Morgan, of Tahon Springs, Florida, all condemn the hernia operations of Bassini and his successors in letters to Randall which are quoted in his article, and admit to a 25% recurrence rate on the average. Cowell (1930) stated that "the Bassini operation is now obsolete and only of academic interest."

On the other hand, a great deal of confidence is reposed in the Bassini operation by many workers (Farr, 1927), and some even claim only 2 or 3% recurrences with it. A great gulf separates the two extremes of thought. Some idea of the value of the Bassini operation and its modifications to-day may be gained by an examination of the writings and experiences of the last half-century.

Multiplicity of Modifications

One of the most damaging pieces of evidence which can be laid against the Bassini operation is the fact that so many surgeons have adopted their own modifications. The reason for this surely must be that in their hands the results of the Bassini operation were unsatisfactory. Unfortunately, none of the modified operations give uniformly better results than the original (Turner, 1937). In an extensive survey of the literature I have found over 70 modifications of the original Bassini. Many of these are almost identical and have been claimed as original by their designers, unaware that others at an earlier date had tried the method and found it wanting. No useful purpose is gained by listing those many suggestions, but it may be said that they have concerned each and every possible anatomical structure in the region of the inguinal canal, and altered each structure in ways as ingenious as they are numerous. But most of the modifications have one common factor—an attempt at union between the conjoined tendon and Poupart's ligament. It is reasonable to believe that in that step may lie the reason for the indifferent results found by so many people.

Indications for Reinforcing the Posterior Canal Wall

In a small or moderate-sized indirect hernia, where the muscles are undamaged by distension and the rings are sound, the posterior wall of the canal is generally found at operation to be strong enough to fulfil its functions of support. Why, then, should any endeavour be made to strengthen it? In cases where the sac is of the congenital type, or where the history leads one to believe the condition is congenital, if the muscles are sound there is no need to strengthen them. Nature is better than man at guarding anatomical danger spots. In any case 75% of the recurrences after Bassini operations take place at the internal ring—the spot, or one of the spots, which the operation has been designed to protect (Turner, 1937). In many cases the precipitating cause of the hernia lies probably in some unexpected strain imposed on the internal ring taking the muscle sphincters unawares. If the congenital sac is removed in these cases, any tear of the fascia transversalis repaired, and the lateral pillars of the internal ring sutured to narrow the opening, the probability is that a good result will be obtained (Fallis, 1936).

Abnormalities of the Conjoined Tendon

Support requires to be given to the posterior wall in all cases of direct hernia, and in those in which the muscles are weak and stretching of the canal has followed. But in these circumstances the conjoined tendon is generally also atrophied to a greater or less degree, and is unsuitable as a medium for support to the weakened area. Moreover, it may not insert into the pubis, but may show an abnormal insertion into the rectus sheath some distance above the pubis. This type of abnormality has been discussed by Polya (1906, 1912), Foldes (1920), and Skillern (1922), and is more frequent than is commonly realized.

In a series of 100 consecutive operations by myself upon the inguinal canal for primary indirect inguinal hernia, the nature of the insertion of the conjoined tendon was noted. In 46 cases the structure could be observed attaching to the pubis and forming a stout posterior wall to the medial part of the canal. In 20 the tendon inserted into the rectus sheath at least 1 in. above its lower extremity, and in the remaining 34 the tendon was inserted to the rectus in its last inch. In 15 of these there was poor connexion, by atrophic fibres, to the pubic crest. Therefore, in only 46% of cases in that series were the correct anatomical findings, as described by Gray (1942), found to be present. In 20% the insertion of the conjoined tendon was abnormal, and in the remaining 34% abnormality to a greater or lesser degree existed.

It may be argued that, in the cases examined, abnormal anatomy was sure to be found owing to the presence of a hernial sac, and that this in effect produced the abnormality. As against that argument it may be stated that those cases which showed the abnormal insertion of the conjoined tendon were in eight instances associated with small sacs and that the operation performed was simple herniotomy. Six of the remaining 12 were associated with large herniae in which it was not possible to distinguish cause from effect, and the remaining six were classified as moderate in size. There a repair was performed, but it was considered that the presence of the hernia had not caused atrophy of the conjoined tendon, and that probably the abnormality described owed nothing of its origin to the hernia.

Thus, even where there is an indication for strengthening the posterior wall, the Bassini operation is unlikely to give a satisfactory result owing to the poor material at hand for use in repair. Where the posterior wall is reasonably normal, further support to it by a Bassini operation does not give the necessary added support to the internal ring or area lateral to the pubis (Turner, 1937), which are the fundamental weak spots and sites of the majority of recurrences.

Stein (1942) states that suture of the conjoined tendon to Poupart's ligament is wrong also, because of the fact that nowhere in human economy is muscle used as a buffer, as its functions are motion, locomotion, and stabilization.

Site of Recurrence

Three-quarters of the recurrences of Edwards's (1943) series took place after a Bassini repair. The most common sites of recurrence are: (*a*) the internal ring; (*b*) immediately lateral to the pubis; (*c*) through the posterior canal wall (Watson, 1925). Of these three, only the last is well protected by a Bassini type of repair. If the conjoined tendon is atrophied or abnormal in its insertion the medial part of the canal cannot be effectively guarded, as it is not possible to bring down the medial limit of the tendon to Poupart's ligament.

Recurrence Rate for the Bassini Operation

Study of recurrence statistics is interesting, but is confusing owing to the wide variations in results of different clinics over the world. This applies to statistics regarding any type of hernia repair. Very many variable and uncontrollable factors influence the statistical analysis. First, the question as to what constitutes a recurrence. To the critical eye a small bulge may be accepted as a failure, while a larger one may by others be considered as within normal limits (Grace and Johnston, 1937). Many cases which recur do not return to the same clinic for further treatment, and in the absence of an efficient follow-up system the recurrence figures for the clinic may be gratifyingly low. Certain people state that, this being so, any given clinic has its quota of recurrences arising from other places, and that these migrant recurrent cases cancel each other out from a statistical point of view. This is a beautiful thought but not sound deduction.

The question as to length of time after operation before re-examination is important. Randall (1930) takes the view that success can be based only upon the results of a five-year period or over. This is not the general opinion, and Taylor (1920), Patterson (1928), Fallis (1940), Joyce (1940), Gould (1940), Edwards (1943), and others consider that the vast majority, up to 80%, recur within the first year, while many believe that the majority recur within the first six months. This is the opinion of Coley (1924). My own view is that the recurrence rate rises slowly with every year after operation, but that for practical purposes the majority of recurrences take place within the first year. In my own experience most have recurred within six months.

Many follow-up statistics are based upon a written questionary sent to the patient and returned with his own findings. This method is apt to give a low recurrence rate, as a substantial number of people are unaware at first that they have a recurrence. Nevertheless, bearing in mind the many variable factors, there are published figures which appear to be as accurate as is possible, and for the Bassini operation and its modifications Table I contains representative figures taken from many different clinics. The figures are for oblique inguinals.

TABLE I.—*Recurrence Statistics for Indirect Inguinal Hernia treated by a Bassini Operation*

Surgeon	Operation	No. of Cases	Recurrence Rate (%)
Fallis (1940)	Halsted	1,386	8·6
Fallis (1940)	Modified Bassini	214	13·4
Oudard and Jean (1922)	Modified Bassini	French Navy	10·0
Coley (1924)	Classical Bassini	332	8·7
Massachusetts General Hospital (Andrews, 1924)	Modified Bassini		9·0
Bellevue, N.Y. (Andrews, 1924)	„ „		7·5
Johns Hopkins, Boston (Andrews, 1924)	„ „		10·9
Max Page (1943)	Bassini	London Police	20·2
Selinger (1927)	Classical Bassini	266	18·0
Erdman (1923)	Modified Bassini	1,093	6·67
Taylor (1920)	„ „	816	5·6
Average recurrence rate (%)			11·8

This figure, 11.8%, is the average culled from several sources, and corresponds closely with the general experience of recurrences for indirect herniae in adult males treated by the Bassini operation, classical or modified.

The technique of a Bassini is more likely in theory to afford support to the canal which is the site of a direct hernia. Table II gives an analysis of results with direct hernia from various clinics.

The figures of Gibson and Felter (1930), with those of Coley (1924), are remarkable for being so much better than those of other workers. The explanation for this is hard to seek, as it is improbable that they are technically superior to many others among their gifted colleagues. There is no evidence that Coley and Felter selected their cases, and, according to their account, they conduct a thorough follow-up examination at least one year after operation. Still, the results they submit for direct hernia are superior to those of most other workers. One feels that there must be a reason for this which has so far not been made clear. If their results are due to the excellence of their technique they have much whereon to congratulate themselves.

TABLE II.—*Recurrence Statistics for Direct Inguinal Hernia treated by the Bassini Operation*

Clinic or Author	No. of Cases	Recurrence Rate (%)
Erdman (1923)	—	16·1
Massachusetts General Hospital (Andrews, 1924)	—	1·5
Johns Hopkins Hospital (Andrews, (1924)	—	29·1
Taylor (1920)	77	22
Watson (1924)	—	20
Lyle (1928)	75	13
Fallis (1940)	154	11·6
Lameris	102	28·4
Bruenor	171	18
Taylor	265	18
Coley (1924)	280	5
Max Page	London Police	25·8
Gibson and Felter (1930)	427	6·5
Average recurrence rate (%)		17·6

From an impartial consideration of results from many reputable sources it is shown that the Bassini operation carries with it a recurrence rate, on the average, of 11.8% for indirect inguinal hernia and 17.6% for direct. These figures are too high to be satisfactory.

Union of Conjoined Tendon to Poupart's Ligament

It has been mentioned that all the Bassini operations have one step in common—union of muscle, usually the conjoined tendon, with the inguinal ligament. Therein may lie the source of failure, and extensive investigations have been conducted into the rationale of this step in the technique. Doubt has been expressed whether satisfactory union can be achieved by attempting to unite muscles with tendon. The subject must be approached from both the clinical and the experimental point of view. It should be noted that the structure described as conjoined tendon is tendinous only near its insertion and that in the main it is composed of muscle fibres. It extends from the internal ring medially to the pubic tubercle.

Clinically, Edwards (1943) noted at operation on 53 recurrences after Bassini operations that the internal oblique in most cases was a thin attenuated sheet of pale-brown muscle, and he considered it was unlikely that it could afford much protection to the internal ring or the posterior wall. The findings after recurrences for simple herniotomy showed healthy muscles. He concluded that the Bassini sutures lead to muscle atrophy and result in a weakening of the canal. The evidence of Max Page (1943) supports Edwards's opinion. Page contrasted his figures of 1934, with a 20.5% recurrence rate after Bassini repairs, with those for 1943, when he had improved his results to 12% failures as a result of adopting more conservative methods of treatment, and using herniotomy rather than hernioplasty in those early cases in which muscles were sound. Moreover, in his series there was no selection of cases, and the results are a fair comparison, showing improvement only because of the new method used in treatment. Turner and Eckhoff (1929) give a recurrence rate of 3% for 98 simple herniotomies. These compare very favourably indeed with the figures for the Bassini lists in Tables I and II.

It is not reasonable to blame the attempt at union of conjoined tendon to Poupart's ligament for the high incidence of failures unless experimental and pathological evidence confirms this. Seelig and Chouke (1923) attacked the problem experimentally, and found, when they sutured a flap of fascia lata in a dog to the underlying muscles, that the sutures were liable to cut out. Even where they did not cut out, union took place only by means of thin scar tissue which was easily stretched.

Burdick (1928) found that suturing fascia to muscle led to healing by means of delicate scar tissue, which developed from the areolar membrane investing the surfaces and from the loose connective-tissue stroma separating the bundles of fibres. He stated that the scar is not strong, and if subjected to strain slowly stretches. Where linen or silk was used instead of catgut the tendency to stretch was not so marked, but often the linen cut out and gave the same result as when catgut had been used. Scarification of the tissues before stitching increased the density and strength of the scar, but prolonged and unusual strain still resulted in its yielding. Side-to-side suturing, as when conjoined tendon is applied to Poupart's ligament, never resulted in permanent adhesions, but yielded after slight strain.

MacGregor (1930) has stated that in his opinion muscle will not act efficiently when sutured so as to alter the direction of its normal line of fibres. Fibrous degeneration, he says, follows at an early date. He also believes that firm union is possible only when fascia is stitched to fascia or muscle to muscle, but not when muscle is stitched to fascia. Koontz (1926) further investigated the problem, but failed to verify Seelig and Chouke's findings in their entirety. He showed in one series of experiments that muscle did unite to fascia, but only when the areolar tissue had been thoroughly removed before suturing. The strength of the resulting scar depended on the intimacy of contact between the two structures. If this union was not close enough, stretching took place at a later date. Rosenblatt and Meyers (1928) also succeeded in promoting union between muscle and fascia, verifying the work of Koontz, but suggested that the main factor in effecting it is tight tying of the sutures. This, they said, induces a fibrin reaction which is later transformed into connective tissue.

A further contribution by Rosenblatt and Cooksey (1927) described the findings in 21 operations on dogs wherein the internal oblique or rectus muscle was sutured to the inguinal ligament with silk gut. It was found 40, 60, and 70 days later that there was firm union between the muscle and fascia in all cases. The union did depend, however, on complete removal of all areolar tissue, and the strength of the scar also had a relation to the area of the surfaces in contact. They stated that to permit the areolar tissue to remain is to invite the situation which exists in a joint—that is, non-adherence of insulated structures. The union takes place when, by removal of all this areolar tissue, there is intimate contact between the muscle bundles and the adjacent fascia or tendon. The muscle bundles are surrounded by a sheath of white fibrous connective tissue, and each muscle fibre has its neighbour bound to it by the same element. The entire muscle or group of bundles is also held together by white fibrous tissue. The elements for a connective-tissue union therefore are present, and explain how union does take place. The muscle is united to the fascia or tendon by scar tissue. There is no conversion of muscle cell to fascia.

G. W. and K. Roberts (1925) agreed with Seelig and Cooksey, and stated that it is rarely possible to achieve sound union between elements which are of different structure. They, with Cowell (1930), stated that as Poupart's ligament is of white fibrous tissue, and conjoined tendon is of red muscle, union by firm scar tissue cannot take place. The experimental findings are somewhat conflicting, but the consensus of opinion is that union does occur, only under definite conditions which demand that all areolar tissue is removed from the areas to be approximated, and that the sutures be applied under tension. Union then takes place by scar tissue, which is apt to stretch under strain. On the practical side further evidence comes from the operating theatre. It is recognized that in many cases of repair Bassini sutures are applied to tissues which are reasonably well developed and that apparently a firm reinforcement of the entire posterior wall will be effected. Yet, when operating on the same cases again for recurrence, the lower part of the conjoined tendon is found to be atrophied, and recurrence has developed just lateral to the pubis. This can be considered only as a pressure atrophy due to necrosis at the site of the tight sutures. This observation has been made in the literature by several writers (Fantino, 1912; Fairfield, 1915; Burian, 1919), and my own experience confirms it.

It may be stated, after consideration of the practical and experimental evidence, that in this step common to all Bassini operations there may be one reason for their comparative failure in some hands. It is probable that areolar tissue is left in many cases and prevents firm union taking place between the conjoined tendon and Poupart's ligament. Secondly, the anchoring sutures may cause necrosis of the muscle, or, alternatively, they may not be tied tightly enough to maintain muscle and ligament in apposition.

The Bassini Operation and the Small Indirect Hernia

There still is one factor which may help to explain the failure of the Bassini: its application to cases which do not require plastic repair at all. It cannot be over-emphasized that if the muscles and rings are competent there can be no indication for plastic repair of any kind. Removal of the sac is sufficient in these cases (Russell, 1906, 1922, 1925; Ogilvie, 1937), and the performance of Bassini repairs is not only useless but actively harmful, predisposing to recurrence by causing atrophy of the lower fibres of the conjoined tendon.

Reasons for Failure of the Bassini Operation

The Bassini operation may fail for the following reasons:

1. Because it is applied to cases not requiring plastic repair.
2. Because when used—as, for example, in direct hernia—the conjoined tendon may be so atrophied that it is of but little value as a means of support.
3. Where it is used with normal muscles it predisposes to recurrence through causing pressure necrosis and atrophy of the lower fibres of the conjoined tendon.
4. Because even when used in cases worth repair it still fails to guard the medial portion of the posterior wall of the canal, and may also not guard the internal ring.
5. Because frequently the conjoined tendon is sutured to Poupart's ligament before all the areolar tissue over the parts has been removed with meticulous care, thus achieving poor union.
6. Because the sutures have been tied too slackly.

It follows from discussion of the available facts that the Bassini operation is found wanting from points of view of end-results, rationale, and technique—at any rate, in the opinion of a considerable number of workers. There are, of course, many other causes of recurrence, common to almost all operations for hernia, but the purpose of this paper is only to discuss the steps in repair which are peculiar to the Bassini operations. Therefore, failure to remove the sac completely or to ligate it properly, the missing of a second sac, and so on are not considered in this contribution.

In view of these considerations, some alternative method must be adopted for those cases requiring plastic repair, and before it can be claimed superior to the Bassini it must from every point of view be demonstrated to be of greater soundness.

It seems from the evidence to hand that, despite the satisfaction in the Bassini operation or its modifications expressed by many surgeons, the operation fails in its results when compared with those of other methods. Where repair is called for the results of living fascial sutures are superior. There is not space in this communication to give the case for fascia as opposed to the Bassini, but Andrews (1928), Lyle (1928), Cattell and Anderson (1931), Foster (1936), Robins (quoted by McClosky and Lehman, 1940), Gray (1940), Edwards (1943), and many others have found in fascia the answer to the problem.

Where the hernia is small and the muscles are sound Max Page (1943) and others have noted an improvement in their results by abandoning the Bassini operation in favour of a more conservative procedure.

Conclusions

The Bassini operation is criticized on the following grounds:

1. The conjoined tendon often inserts abnormally into the lower part of the lateral aspect of the rectus sheath rather than the pubis, and thus when stitched to Poupart's ligament leaves a deficiency medially in the canal through which the recurrence may take place as a direct hernia.
2. In large and in direct herniae the conjoined tendon is frequently atrophied to a greater or less degree and is unsuitable material for reinforcing the posterior wall of the canal.
3. Even where the conjoined tendon is suitable for repair, union with Poupart's ligament can take place only by means of scar tissue, and then only when all areolar tissue has been removed from the surfaces that are to be united. The scar tissue readily stretches.
4. In the small type of hernia and where the muscles of the area are sound, experience has demonstrated that better results are obtained by simple removal of the sac and, if necessary, by reinforcing the fascia transversalis.

5. The clinical results of the Bassini operation in repair of direct inguinal hernia are associated with a recurrence rate which is too high for satisfaction and which is higher than the recurrence rate associated with fascial repair.

6. The clinical results for indirect inguinal herniae which need repair are associated with a recurrence rate again too high for satisfaction, and higher than that associated with fascial repair.

The fact remains that many workers maintain that the Bassini operation or one of its modifications gives good results in their hands. This contrasts with the experience of many sound surgeons and of important teaching centres where the operation has been tried and found wanting. The reason for this conflict of thought is obscure and probably insoluble.

It may be said that no expression of opinion in regard to the efficiency of an operation is of value unless supported by careful follow-up examination not only for recurrence but for late post-operative morbidity. Papers have been published describing the late morbidity after operations for the repair of hernia by several methods, and again the conclusions in regard to the Bassini are somewhat less satisfactory than those for fascia (Bloodgood, 1899; Erdman, 1923; Russell, 1925; Lyle, 1928; Patterson, 1928; Gibson and Felter, 1930; Foster, 1936; Fallis, 1940).

Although opinions differ in regard to the treatment of hernia there is agreement, at any rate, about one thing—that the treatment of hernia is highly controversial, has been for many years, and is likely to remain so for many more. Such a state of affairs can arise only where the results of treatment fail to reach the highest levels of satisfaction; and until some advance is made which will conclusively and universally solve the choice of operation for hernial repair controversy is likely to rage.

E. J. Donovan and T. V. Santulle (*Amer. J. Dis. Child.*, 1945, **69**, 176), who record ten cases, state that, though gastric and duodenal ulceration are rare in infancy and childhood, the diagnosis would probably be made much more frequently if it were realized that it may occur at this age. Haemorrhage, which is the commonest complication, was found in six out of the ten cases. Perforation and pyloric stenosis were also observed. Malignant disease was not encountered.

BASSINI'S OPERATION FOR INGUINAL HERNIA

BY

THOMAS L. GORDON, F.R.C.S.Ed.
Dispensary Surgeon, Western Infirmary, Glasgow

During the last few years the value of Bassini's operation for inguinal hernia has been deprecated, and many alternative procedures have been recommended. In my view there is, however, still a wide field of usefulness for Bassini's method, and, provided the technique is skilfully applied, the results are as good as, if not better than, most of the other procedures. Naturally, this operation is not indicated in every case of hernial repair, and its choice in any particular instance can as a rule be definitely decided only when the canal is exposed. In the young or even in the middle-aged, with good musculature and a well-formed inner ring, usually no more is required than a thorough removal of the sac, but in patients with poor musculature, a weak transversalis fascia, and a large internal ring Bassini's operation gives very satisfactory results. The following is the procedure usually adopted.

Technique

After the usual skin toilet an inguinal incision is made, 3 to 4 in. long, in the line of the inguinal canal; a good length of incision is advisable for proper exposure. Haemostasis must be complete throughout and, where possible, vessels are picked up before division; this prevents staining of the tissues and allows clearer differentiation of the various structures. The external oblique aponeurosis is then divided by making a small incision 2 in. from the external ring and, with a pair of scissors, cutting from this incision along the line of the fascia to the centre point of the external ring and upwards as far as the level of the internal ring. Both upper and lower margins of the fascia are picked up by two pairs of pressure forceps. Traction through these forceps is now applied to the upper layer, and with a gauze swab it is freed from the underlying internal oblique and rectus abdominis, as far as this can be carried out without undue force. The lower layer is pulled down and the upper surface of the inguinal ligament is well exposed by gauze dissection of the areolar tissues. At this point two nerves are noted—the ilio-hypogastric and ilio-inguinal; the latter, lying along the cord usually on its anterior surface but occasionally on its lower and posterior, is picked up, divided, and ligatured at both ends, as there is usually an accompanying vessel; the ilio-hypogastric, running superior to the cord below the external oblique aponeurosis, may have to be treated in a similar fashion if it is so low that it might be included when suturing this later.

The cremasteric muscle is divided along the line of the cord and the latter is lifted from its bed, two small gauze swabs being passed below it to allow light traction. Below the cord, where it lies over the pubis, the areolar tissue is cleared, either by gauze or scissor dissection, depending on its thickness, until the inner end of the inguinal ligament, the pubic spine, and the approximating area of the pubis are clearly exposed. Dissection of the cord in the usual manner is carried out until the sac has been well separated, and this is ligatured as high above the neck as possible, the internal oblique being retracted to enable this to be done satisfactorily. It is possible that retraction of the epigastric vessels may also have to be carried out to give good exposure for this procedure.

The cremasteric muscle and fascia are now dealt with. This muscle is very variable, sometimes being exceedingly thick and tending to interfere with proper repair. In some cases it is not necessary to remove it, but in the majority it is better to do so completely, as this allows closer approximation of the internal oblique to the inguinal ligament. If the remaining part of the cord is still very thick or contains a large mass of veins, portions of these should be removed to allow more accurate closure of the external ring. For obvious reasons care should be taken not to remove too much of the pampiniform plexus. Running over the transversalis fascia are some veins which, at times, may be very large and closely adherent to the cord at the level of the external ring, and it is as well to ligature these in two places, removing the intervening portion and leaving the bed of the canal clear.

One is now ready to carry out the repair. Using No. 1 or No. 2 chromic 20-day catgut, interrupted sutures are inserted at 1/2 in. intervals. The first of these takes in the lower portion of the rectus, the conjoint tendon, and the periosteum of the pubis close to the pubic spine. The next includes the conjoint tendon and inguinal ligament, and the remainder the internal oblique, transversus abdominis, and inguinal ligament; with each a good bite of the muscle is taken, the needle being inserted 1/2 to 3/4 in. from its lower border. The last suture closes the internal ring until only the tip of the forefinger can be inserted comfortably; occasionally, if the ring is very large, an extra suture is put in on the outer side of the cord. A continuous suture of No. 0000 chromic 20-day catgut is inserted over the interrupted sutures, picking up the muscular margin and the inguinal ligament. When inserting the needle into the inguinal ligament, for both the interrupted and the continuous sutures, slightly different levels are taken to prevent splitting of the fibres. The remains of the cord are now laid back in this bed and the external oblique aponeurosis is sutured with No. 0 chromic catgut till the external ring admits the tip of the forefinger. The deep fascia is sutured with No. 0000 chromic catgut and the skin wound closed with interrupted silkworm sutures. After dressing, a firm spica bandage is applied.

After-care.—The stitches are removed on the 8th to 10th day and the patient is kept three weeks in bed, and a further two months must elapse before he starts heavy work. For the first week patients are nursed so far as is possible in the extended position, as it has been found that in some cases in which a knee pillow has been used or they have been allowed to sit up there is a complaint of slight discomfort in the groin of a dragging nature for a few months after the operation. After the first week, however, they can move about the bed as much as they care to do, although no special exercises are performed, but, when lying, the leg on the affected side should be kept extended. After leaving hospital the only instructions given are, for a period of three months, to lift no heavy weights which would necessitate their having to hold the breath to do so, as when the diaphragm is fixed in this manner a very considerable strain is put on the inguinal regions.

Points regarding the Operation

The *transversalis fascia* varies considerably in its strength. In some it is a good solid structure which could be used for repairing the posterior wall of the canal, but in the great majority it is thin, and by itself would be unlikely to stand up to much stress, particularly in cases of direct hernia. Bassini himself, however, used to divide the fascia and overlap it as well as bringing down the internal oblique muscle. This fascia is closely adherent to the under-surface of the internal oblique, and when this muscle is brought down there is bound to be a degree of plication and ultimate contraction. In cases in which the inner ring may be on the wide side and this fascia is of good quality there does not appear to be any reason why it should not be used for narrowing the ring, and in cases of direct hernia a wedge should be removed, after which the edges are sutured and the usual repair then done.

Internal Oblique.—When this muscle is brought down to the inguinal ligament before separating it from the external oblique there is often considerable tension, but once this manipulation is carried out remarkably little tension occurs in the great majority of cases. It has been contended that the margin of the muscle is destroyed and that its valvular function is diminished. This, however, is quite definitely not the case when the operation has been performed satisfactorily. The margin of the muscle does become stretched, attenuated, and fibrosed; but it forms a very excellent posterior wall to the inguinal canal, and if, in these cases, a finger is put into the internal ring and the abdominal muscles are contracted it is quite obvious that there has been no loss of function in the musculature of this region.

Occasionally at the inner angle considerable tension on the suture is present, and in these cases a flap from the anterior sheath of the lower rectus can be turned over to cover this defect, or a vertical relieving suture in the fascia can be made. In only one of the series quoted below was the latter procedure required.

Inguinal Nerve.—In all the cases cited below the ilio-inguinal nerve has been removed without any complaint afterwards of numbness or other symptoms. It is advisable to remove this nerve, for if it becomes incorporated in any fibrous tissue a very acute ilio-inguinal neuritis can be set up, and the canal has to be reopened and the nerve removed. Recently a patient had to be operated on for this complication after a Bassini operation had been performed elsewhere. As well as finding that the nerve had been incorporated in the external oblique sutures, it was noted how well the posterior wall of the canal and the internal ring were supported by the attenuated muscular bed.

Results

This paper is a review of 143 cases, submitted to Bassini's operation since 1936, by either Mr. A. J. Hutton or myself, in Mr. Hutton's wards in the Western Infirmary. They included all types of hernia, both simple and strangulated, and all ages. In the whole series there were two deaths, both of these in patients over 70 operated on for strangulated hernia.

A questionary was sent to all survivors, and 118 replies were received. Of these, eight had since died from some other cause than the hernia, which apparently was quite satisfactory at the time of their death, but they are not included in this list. In 10 cases the letters were returned "Not found," leaving 100 cases suitable for analysis. In the 100 cases 107 herniotomies were performed. These were subdivided as follows: bilateral, 7; right direct hernia, 8; left direct hernia, 6; right indirect hernia, 47; left indirect hernia, 32. Of this series 5 were recurrent and 11 strangulated. The age groups were: 10–20 years, 4; 20–30, 11; 30–40, 19; 40–50, 20; 50–60, 27; 60–70, 16; 70–80, 2; 80–90, 1.

Altogether there were three recurrences: the first of these was in a man 48 years of age, with a direct hernia and exceedingly poor musculature, and not really very suitable for this type of operation; the second, in a man of 65 who had had a bilateral operation nine years previously and had developed a recurrence with strangulation, also of the direct type of hernia, and with very poor musculature. The third of these patients, a man aged 62, returned to his work very shortly after operation and slipped while lifting a heavy weight, after which his hernia recurred.

The average time before resuming work was eight weeks, varying from three weeks to six months, and all returned to their normal occupations except four who were over 60, and of these two retired and two returned to lighter work.

Bassini's series of cases, numbering 216 simple herniae between 1884 and 1889, showed a recurrence rate of 3% and a suppuration rate of 5%. In the cases quoted above, beyond slight reddening of the skin round the silkworm sutures in a few cases, no further evidence of sepsis was found. At the Pio Istituto Bassini at Milan, where this operation is the method of choice, in a series of 10,000 cases, they state that the recurrence rate is between 1 and 2% for simple herniae.

Although figures can be very misleading they do give a fair indication when assessing results, and those quoted compare favourably with any given previously. This operation should therefore be considered as a standard operation and especially indicated in the middle-aged and old where a fairly satisfactory musculature is present. It must, however, be meticulously carried out to obtain satisfactory results. In fact, the tissues —both muscular and fascial—have to be exceedingly poor before the operation is contraindicated. The technique is easily acquired, and there is much less scope for error than in many of the procedures in common use to-day.

RELATION BETWEEN GASTRIC ACIDITY AND THE ANTERIOR-PITUITARY-LIKE HORMONE CONTENT OF URINE IN PREGNANT WOMEN

BY

STANLEY WAY, M.R.C.O.G.

Assistant, Department of Obstetrics and Gynaecology, the Medical School, King's College, Newcastle-upon-Tyne

(From the Laboratory of the Princess Mary Maternity Hospital)

The earliest observations on gastric acidity in pregnancy were made in 1925 by Nakai, who showed that there was a striking diminution in both the free and the total acid content of gastric juice in response to a test meal. This was confirmed by Artz (1930) and Anderson (1932), both of whom drew attention to the fact that the lowest secretion of free acid coincides with the period of pregnancy when nausea and vomiting are common. Strauss and Castle (1932), investigating anaemia in pregnant women, confirmed that secretion is diminished, and further showed that there is a rise in secretion of free acid in the last month of pregnancy and a very great rise immediately after delivery. They also showed that the gastric response to histamine was greatly diminished.

In 1938, during a statistical investigation into the incidence of hyperemesis gravidarum, I noticed an extraordinarily high incidence of this disorder in patients who were suffering from hydatidiform mole. Since hydatidiform mole is associated with the presence in the urine of large amounts of anterior-pituitary-like hormone it appeared to me that this hormone might be responsible for the low secretion of acid in the gastric juice.

Soon after this work was started an important piece of experimental evidence was published by Culmer, Atkinson, and Ivy (1939). They showed that in dogs with Pavlov pouches the secretion of free and total acid could be very greatly diminished, even after histamine, by the injection of fairly large amounts (1,000 to 5,000 rat units) of anterior-pituitary-like hormone. They were unable to produce this effect with any other hormone known to be secreted in excess during pregnancy.

It is well known that the secretion of anterior-pituitary-like hormone rises rapidly after the 28th day of pregnancy and reaches its maximum between the 56th and 84th days, when there may be as much as 50,000 rat units per litre in the serum, and the secretion in the urine may be as high as 150,000 rat units in 24 hours. Then there is a falling off, and at full term the amounts, although greater than in the non-pregnant, are comparatively small.

Method of Investigation

For the purpose of this investigation it was decided to correlate the secretion of free and total acid in response to a test meal with the secretion of anterior-pituitary-like hormone in the urine. Wartime conditions prevented estimations in units per 24 hours being made, so samples from 24-hourly specimens were taken and Aschheim-Zondek reactions performed on undiluted samples, and samples diluted 1 in 5, 1 in 10, and, in half the cases, 1 in 100. Since this high dilution gave almost consistently negative results it was abandoned. The technique of the test meal was that described by Dodds and Whitby (1931). Histamine was not used. Investigation was made of 63 patients, who gave no history of gastric disorders. Twenty-two were between the 35th and 40th weeks of pregnancy; 20 between the 20th and 29th weeks, and 21 between the 8th and 16th weeks. In addition four other patients were studied. One of these had a missed abortion and one a dead foetus at full term; one had a hydatidiform mole and one a chorion-epithelioma. Seven were studied at different stages of pregnancy and 12 before and after delivery or termination of pregnancy.

Results

Chart I shows the average secretion of free HCl, in three groups of patients, according to the period of pregnancy.

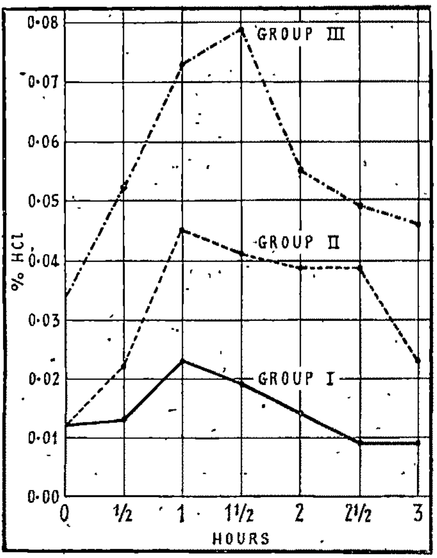

Chart I, showing average secretion of free HCl in three groups of patients according to period of pregnancy.

Group I (8–16 weeks) showed a maximum secretion of 0.023% HCl
Group II (20–29 weeks) „ „ „ 0.045% HCl
Group III (35–40 weeks) „ „ „ 0.079% HCl

Two normal pregnancies gave a positive Aschheim-Zondek reaction at 1 in 100; 28 were positive 1 in 10; 15 were positive 1 in 5, negative 1 in 10; and 18 were positive but negative in dilution. These cases form Groups A, B, and C in Chart II, which shows the average secretion of free HCl according to the degree of dilution in which the Aschheim-Zondek reaction was positive. Two cases positive 1 in 100 are included in Group A.

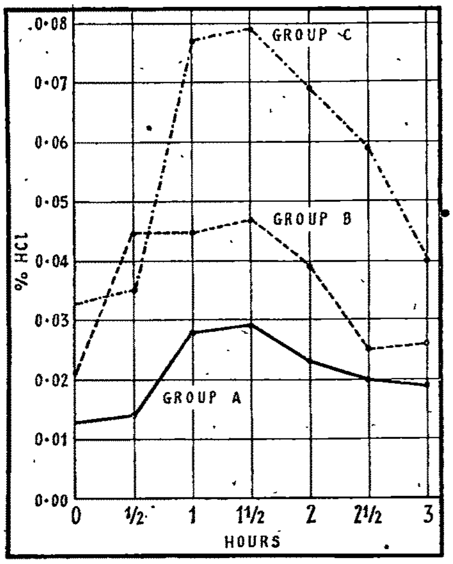

Chart II, showing average secretion of free HCl according to degree of dilution in which the A.-Z. reaction was positive.

Group A—positive 1 in 10—shows a maximum secretion of 0.029% HCl

Group B—positive 1 in 5, negative 1 in 10—shows a maximum secretion of 0.044% HCl

Group C—positive, but negative in dilution—shows a maximum secretion of 0.079% HCl

In all three groups the maximum secretion occurred at 1½ hours.

Chart III shows the average secretion of free hydrochloric acid in 12 cases immediately before delivery or termination of

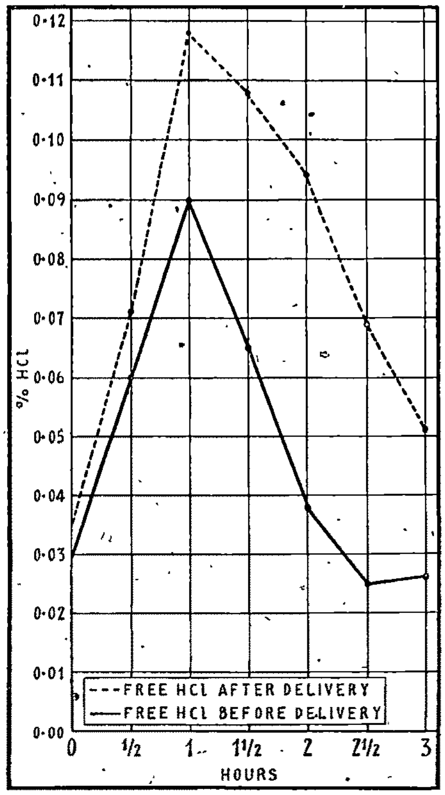

Chart III, showing average secretion of free HCl in 12 cases immediately before delivery or termination of pregnancy and average secretion of same 12 patients one week after delivery.

pregnancy (maximum secretion 0.09% HCl) and the average secretion of the same 12 patients one week after delivery (maximum secretion 0.118% HCl). In these patients the Aschheim-Zondek reaction was completely negative on the second occasion.

The case with the dead foetus at full term and the missed abortion at 12 weeks both showed a normal response and had negative Aschheim-Zondek reactions. The chorion-epithelioma followed a hydatidiform mole. The patient was first seen three days after aborting the mole; the Aschheim-Zondek was weakly positive, but negative in dilution, and the maximum secretion 0.02% HCl. Six weeks later, when she had a large malignant mass in the uterus, there was complete achlorhydria, and the Aschheim-Zondek was positive up to a dilution of 1 in 100. Hysterectomy was performed, but the patient died after operation and no further studies were possible. The patient with the hydatidiform mole was not studied while the mole was present. When seen six months later the Aschheim-Zondek was positive up to 1 in 10 and the maximum secretion 0.124% HCl. No evidence of chorion-epithelioma could be detected at this time. Four months later the Aschheim-Zondek was only weakly positive and the maximum secretion 0.302% HCl.

The seven patients who were studied more than once in pregnancy showed a low secretion of acid (average 0.036%) when the Aschheim-Zondek was strongly positive in early pregnancy and a much higher secretion (average 0.078%) towards term, when the prolan secretion was very much lower. The total acidity ran a course very similar to the free acid, with the exception that it was depressed to a less extent and that the difference between the curves for high and low prolan concentrations was less than in the case of free acid.

Comment

The hypochlorhydria of pregnancy has been ascribed to the neutralizing effects of regurgitated duodenal contents. Bile appeared in fewer than 3% of my specimens, and some of these contained large quantities of free acid. Strauss and Castle (1932) also found but few bile-stained specimens, and are of the opinion that duodenal regurgitation is not the cause of hypochlorhydria.

Evidence is brought forward here to show that in human pregnancy there appears to be some relation between the free and total acid in the gastric juice and the amounts of anterior-pituitary-like hormone secreted in the urine, and that it seems to be inversely proportional. Further studies are being made.

I wish to thank the members of the staff of the Princess Mary Maternity Hospital, Newcastle-upon-Tyne, for allowing me access to cases under their care; my friend Dr. Frank Dickens for his advice and constant encouragement; Dr. Ruth Dearing and Dr. E. Wilkinson for their invaluable help in collecting specimens; and, last but not least, the 67 patients who so willingly submitted to these investigations.

The costs of this work were defrayed by a grant from the Research Committee of the Council of King's College, Newcastle-upon-Tyne.

The 93rd annual report of the Board of Management of the Hospital for Sick Children, Great Ormond Street, says that during the period of the flying-bomb and rocket attacks as many children as possible were accommodated for safety in the various wartime country branches, but all the beds that could be made available in London were fully occupied. The hospital fortunately suffered only minor damage as a result of the attacks, and the casualty department gave service to many injured adults and children from outside. The report pays tribute to the late Sir Thomas Barlow, who was a member of the medical staff in various capacities for not less than 70 years, and continued to take a personal interest in the work long after his retirement from the active list. In the history of Great Ormond Street Sir Thomas held a unique position, for he was the last personal link with the founder of the hospital, Dr. Charles West, under whom he served in his earliest years. Another distinguished physician and very good friend was lost by the death of Dr. Hugh Thursfield, for 36 years an active, and afterwards consulting, member of the staff.

DIARRHOEA DUE TO GIARDIA LAMBLIA

BY

J. F. FRASER, M.B.
Lieut.-Col., R.A.M.C.

AND

ROBERT TAYLOR, M.B.
Capt., R.A.M.C.

It had long been considered that the flagellate *Giardia lamblia* (which name is adopted here instead of *G. intestinalis* or *G. enterica*, as it is in more common use) was non-pathogenic, and Napier (1944) states that until recently he had questioned its pathogenicity except in children; but in the last few years, since the introduction of a specific treatment by Brumpt (1937) and Martin (1937), all his doubts have been dispelled. Manson-Bahr (1943), too, states that all authorities are by no means agreed as to the pathogenicity of *G. lamblia*. In 1942 a report was made to the Medical Research Council (Ormiston *et al.*, 1942) concerning an outbreak of enteritis due to *G. lamblia* in a nursery for evacuees.

The present series have been studied in the medical division of a British general hospital in India over a period of 18 months. During this period there were admitted 872 cases of diarrhoeal diseases; these were differentiated into the following classes:

1. Bacillary dysentery (Flexner, Sonne, Shiga, Schmitz, and Bayd) (4 of these had associated *G. lamblia*)	237
2. Clinical dysentery (Cases with an indefinite exudate, blood and mucus in the stool, but no isolated pathogenic organisms and no *Entamoeba histolytica*)	184
3. Amoebic dysentery (4 of these had associated *G. lamblia*)	158
4. Diarrhoea with no demonstrable organisms	272
5. Giardiasis	21

The proportion of cases in which *G. lamblia* was present was 3.32%. Napier (1944) records that in Calcutta, between 1935 and 1938, of 20,000 stools examined 6.27% contained *G. lamblia*. He does not state in how many cases the flagellate was associated with other diseases, but his series includes the stools of children, in whom *G. lamblia* occurs more commonly than in adults. The present analysis is confined to the cases in which no other cause was found to account for the diarrhoea. The total number of cases of giardiasis in this series was 21.

Symptomatology

Diarrhoea.—All cases had diarrhoea on admission, the number of stools varying from 3 to 12 in 24 hours.

Pain.—Six cases had no pain. In 15 pain of a colicky nature was complained of, with an urgent desire to go to stool. Evacuation of bowels relieved the pain. In only one case was tenesmus complained of.

Flatulence.—This was not a marked feature except in 2 cases.

General Malaise.—This was usual, but not so prominent as in cases of true dysentery of the same severity.

Fever.—Two cases had a mild pyrexia (100° F.), but in only one did this persist, and then for but four days.

Loss of Appetite.—This was noted only in cases which had been ill for a few days.

Vomiting.—None complained of vomiting.

The average duration of symptoms before admission was 5.5 days; limits, 1 to 35 days. The case lasting 35 days—that of a British officer—was exceptional, as most of the B.O.R.s were admitted on the first or second day of diarrhoea. The only system affected was the gastro-intestinal. The tongue was generally coated. In the abdomen no physical abnormality was detected in 10 cases. Sites of tenderness in the others were located as follows: Generalized, 2; R.I.F., 2; L.I.F., 1; in epigastrium and right hypochondrium, 6—the liver was palpable in two of these cases. In all but two cases the stools were watery faecal, rather paler than normal, but not approaching the colour or consistency of the stool of sprue. Generally they appeared greasy, but no fat estimations were done. In two blood and mucus were present, and in one mucus only. In two cases with a long history of continuous diarrhoea—35 days and 28 days—the stools were bulky, resembling those of sprue in consistency but not in colour.

In eight cases there was no history of diarrhoea previous to the present attack. The others gave a history of repeated attacks of diarrhoea for some weeks, and three reported alternating constipation and diarrhoea. In only one case was there a history of bacillary dysentery.

Treatment

All cases were given a five-day course of mepacrine 0.1 g. t.d.s. The stools were examined on three successive days after completion of treatment, and on all but two *G. lamblia* had disappeared. After a second course both were found to be clear. All cases were given a generous diet as soon as the diagnosis was established, and symptoms disappeared by the third day of treatment. The duration of stay in hospital was 14 days; limits, 9 to 41. The 41-day case was that of the officer mentioned previously. He had lost a great deal of weight and required building up. One other case, which had furunculosis as well as giardiasis, was in hospital for 31 days. Owing to the rapidly changing personnel of the station it was possible to follow up only two cases. One had recurrence of diarrhoea after nine months, but on this occasion the cause was bacillary dysentery, and no *G. lamblia* was found. The second had had recurrent diarrhoea for some months, but has been free for three months since his treatment.

Comment

With the exception of two cases all were admitted to hospital when the fly season was at its height. In 1944 seven cases came from one camp and seven from another. A large number of flies from the traps were examined, but no *G. lamblia* cysts or flagellate forms were detected.

It will also be noted that the description of the stools differs somewhat from that of Manson-Bahr (1943), except in two cases with long histories. It is possible that in the Army one gets the cases into hospital at an earlier stage than in civil practice, and this may explain the difference.

Summary

Twenty-one cases of diarrhoea believed to be due to infestation with *G. lamblia* are described. The percentage in relation to other diarrhoeal diseases is stated. Symptoms, physical signs, and treatment are discussed. Two cases have been followed up for a short period.

We wish to thank Major J. L. Dales, R.A.M.C., and Major M. Joseph, R.A.M.C., pathologists, for their examination of the stools; and Col. F. Cook for permission to publish this paper.

Medical Memoranda

Giardiasis associated with Recurrent Rectal Haemorrhages

It may be of interest to record a case of giardiasis associated with the passage of large amounts of blood. Infestation with *Giardia lamblia* is common in Fiji, often symptomless, and in no other case have I found it associated with the passage of blood per rectum.

Case History

The patient was a female child, 4 years old, of mixed Fijian and European descent. She first entered the Colonial War Memorial Hospital on March 13, 1944, with a history of fever, constipation, and weakness, and the passage of blood with the stools. She appeared a normal well-developed child, and general physical examination revealed no abnormality. At subsequent examinations there was a vague abdominal tenderness but no guarding. She remained in hospital till May 6, during which time the stools were persistently accompanied by the passage of blood. At times the blood was clotted, at times bright red, and mucus was often present. The stools were soft and pale, and frequently there was diarrhoea. Investigations made during the period March 13 to May 6 included five stools which were negative for worms and ova and cysts, and for bacillary dysentery. On April 12 the haemoglobin was 80% and the red cell count 3,100,000. Sigmoidoscopy revealed no abnormality. The haemorrhages became less, her general condition improved, and she was discharged to the out-patient department.

She was readmitted on May 12 with a recurrence of blood-stained stools for three days before admission. Physical examination was again negative. Further investigations of the stools revealed the presence of *Trichuris* on May 18, and on May 27 heavy infestation with *Giardia lamblia*. Eight further stools submitted subsequent to treatment of the *Giardia* infection were negative for that parasite, though hookworm and *Trichuris* were afterwards found and treated. The Widal test was negative for *E. typhosa* on May 27, and barium enema and radiographs of the chest showed no abnormality of the large bowel or lungs. The anaemia was at its worst on June 1, with haemoglobin 60% and red cells 2,800,000. Apart from treatment of the anaemia the patient was given 3/4 grain of mepacrine hydrochloride three times a day for 5 days following the discovery of *Giardia* on May 27. This course was repeated after 10 days' interval. After the first course of mepacrine no blood was observed with the stools, and eight further stools were negative for *Giardia*.

The patient was discharged on June 22, 1944, her general condition having gradually improved since the course of mepacrine.

My acknowledgments are due to Dr. V. W. T. McGusty, C.M.G., O.B.E., Director of Medical Services, Fiji, for permission to publish this case.

Suva, Fiji. Medical Officer, Colonial War Memorial Hospital.

Spontaneous Lobectomy

The description of a case of spontaneous lobectomy associated with *Bacillus friedländeri* infection by J. W. Taylor (*B.M.J.*, 1944, **2**, 500) has prompted me to put on record two further cases of this uncommon condition.

Case I

A man aged 41 was admitted to Queen Elizabeth Hospital, Birmingham, on Feb. 3, 1942, under the care of Dr. A. Brian Taylor. He gave a history of two weeks' illness, beginning with a rigor and continuing with pain in the right side of the chest, cough with blood-stained sputum, dyspnoea, and pyrexia. He had been treated with sulphapyridine. On admission he was thin, dyspnoeic, looked ill, and had a temperature of 100°. Clinical examination suggested a moderately large right pleural effusion, more posterior than anterior. This was confirmed by radiographs, a lateral view showing a convex anterior border to the shadow. Aspiration produced thick brown foul-smelling pus, which on culture yielded a heavy pure growth of *B. friedländeri*. The sputum was purulent, and contained a heavy mixed bacterial flora with a marked preponderance of *B. friedländeri*. On Feb. 5 drainage of the empyema was performed under local analgesia, a portion of the 9th rib being resected. The cavity extended upwards and forwards and was limited below by necrotic tissue. Closed drainage was instituted for 12 days, and then open drainage, and pleural wash-outs were started. On the 18th day after aspiration, while a pleural wash-out was being performed, the patient had a fit of coughing, and through the sinus he coughed a piece of tissue corresponding in size to a large portion of the lower lobe. Although necrotic, its pulmonary structure was quite recognizable. Progress henceforward was satisfactory, and although the sinus continued to discharge for a few months it eventually healed and has remained dry. The patient is now back at work.

Case II

A man aged 49 was admitted to this hospital on Jan. 25, 1944, under the care of Dr. A. Brian Taylor. He gave a history of "influenza" two months previously, followed by cough, high temperature, and delirium. He was treated with sulphapyridine and improved. Since then he had continued to cough, bringing up purulent sputum and complaining of pain in the left chest.

On admission he was thin and had a temperature of 101°. The percussion note was impaired over the left upper thorax, with diminished bronchial breath sounds. *X*-ray examination showed a fluid level in the left chest, rather anterior, at the level of the third costal cartilage. Paracentesis in the fourth space in the anterior axillary line produced creamy odourless pus which yielded a moderately heavy pure growth of *B. friedländeri*.

On Feb. 3 operation was performed under local analgesia. A portion of the 5th rib was resected in the anterior axilla, and foul thin pus was found and withdrawn. During this procedure a slough of necrotic upper lobe measuring about 10 by 8 by 3 in. came out, and a persistent bronchial fistula was left. Open drainage was instituted; 48 hours later a violent secondary haemorrhage occurred into the pleura and through the tube, and was accompanied by haemoptysis. A blood transfusion of two pints was given, and his condition improved. Some bleeding occurred at intervals for nearly two weeks.

The patient became afebrile and his condition gradually improved, although his cough continued for a time. Three weeks after drainage, radiographs showed in the opposite upper lobe an abscess cavity which had not previously been present, and sputum yielded a heavy nearly pure growth of *B. friedländeri*. This right-sided cavity became smaller and disappeared without any surgical intervention. The patient is now about and feels well, but still has a large sinus with a bronchial fistula. Pleurograms show an anterior apical cavity with several bronchial openings, probably into the pectoral and ventral branches of the upper-lobe bronchus, the axillary-apical bronchus appearing intact.

Comment

Two cases of spontaneous partial lobectomy are described, both associated with pure *B. friedländeri*, pneumonia, and empyema. One was in a lower lobe, and has proceeded to a satisfactory recovery. The other was an upper-lobe lesion, was followed by a violent secondary haemorrhage and by a transient abscess in the opposite upper lobe, and has recovered with a residual broncho-cutaneous fistula.

B. friedländeri appears to have some special ability to cause sloughing of the lung, perhaps through thrombosis of the pulmonary vessels.

I am indebted to Dr. A. Brian Taylor for permission to record these two cases.

Queen Elizabeth Hospital, Birmingham.

A Case of Third-generation Syphilis

The following report of a case recently encountered may be found of interest.

Case History

The patient, a boy aged 14, was brought to hospital by his mother to see whether anything could be done to improve his gait. He had previously attended another hospital, where a W.R. was done but no lumbar puncture performed. The mother was then told that the boy was a congenital idiot, and should be sent to a mental home. No reference at all had been made to syphilis, and no further advice tendered to her.

The boy is the middle of three children, having an elder sister and a younger brother. His was a precipitate delivery, and he had been a weakling since birth. He was completely disinterested in life, and could read and write only with great effort. He could not dress himself, nor could he carry out his toilet unaided. He had never been able to walk properly.

Examination showed that the boy walked with a typically tabetic gait, due to spasticity of the lower limbs. There was slight sensory loss in both feet. The right pupil was dilated and did not react to light, while the left was normal and reacted to light. Both fundi were normal. There were no other signs of syphilis. The blood W.R. was positive. The C.S.F. findings were as follows: W.R., + + +; Lange, 5553210000; cells, 20 per c.mm.; total protein, 30 mg. per 100 c.cm.; globulin, increased.

Diagnosis.—The diagnosis was quite obviously that of congenital taboparesis. On investigating the rest of the family—the two other children, the father, and the mother—the only one who showed a positive W.R. was the mother. She avowed that she had never had syphilis, nor any treatment; but that both her parents had died as a result of the disease. This would indicate that she is herself a congenital syphilitic, even though she shows no signs, apart from that complacent facies which is so often seen. The father had been a blood donor for more than 25 years; it is therefore reasonable to assume that his blood W.R. has been negative all that time, and certainly during the 20 years he has known the mother. Both the daughter, aged 17, and the younger son, aged 12, show no signs of the disease, and are brilliant scholars. It can thus be stated that these three members of the family are, and always have been, free from syphilis; and should the mother have acquired it at all it would have been manifest in one or all of them. The evidence therefore shows that the mother is a congenital syphilitic who has given birth to a third-generation congenital syphilitic.

Comment

Third- and fourth-generation syphilis appears to be rare, and very difficult to prove. It is also evident that congenital neurosyphilis responds well to treatment, provided that the patient does not suffer from fits (see Nabarro, 1934). This is borne out by the progress of the patient, who after his first course of 10 weekly injections of 2 g. of tryparsamide and 0.2 g. of bismuth, showed the following C.S.F. changes: W.R., +; Lange, 0111000000; cells, 2 per c.mm.; total protein, 20 mg. per 100 c.cm.; globulin, slight increase. In addition to these changes, his general condition has improved dramatically. He can now dress himself, bath himself, and goes to school daily. He takes a general interest in life, and is always asking if he may go to the cinema or to see friends—things he had never done before. He asks questions about his treatment, whereas a few months ago he did not care.

The lesson to be learnt from such cases is that those which appear to be the most hopeless may be benefited by treatment. This of course raises the question whether they could be avoided by the administration of arsenic to all congenital syphilitics during pregnancy. Closer investigation into the histories of congenital syphilitics might show the disease to be commoner than is supposed.

Reviews

ANNUAL REVIEW OF PHYSIOLOGY

Annual Review of Physiology. Vol. VII. Editor, James Murray Luck; Associate Editor, Victor E. Hall. (Pp. 774. $5.00 or 30s.) California: American Physiological Society and Annual Reviews Inc.; London: H. K. Lewis and Co. 1945.

The appearance of Volume VII of this *Review* almost coincidently with the end of European hostilities will evoke from physiologists and those who wish to keep abreast with physiological literature an expression of gratitude for the boon this publication has been through the war years. The sense of misgiving for introducing a new publication into a world already burdened with scientific literature, to which the editors confessed in the preface to the first volume in 1939, must, indeed, have changed to one of duty as they became responsible each year for presenting their survey of physiological advances. The present volume, the largest yet published, contains 26 articles, compared with 19 in 1944, in which are reviewed almost 4,500 publications representing the work of over 4,000 investigators. It is clear that physiological work has not been at a standstill during the war years, although many of the reviewers in the introductions to their articles stress the diversion of interest from "pure" to "applied" physiology. The lifting to some extent of the security bans on publication during the past 18 months has permitted some of this applied work to be revealed. As an example of this tendency the review of "Applied Physiology" (J. H. Comroe and R. D. Dripps) is devoted to aviation medicine, fitness and performance, and resuscitation; and references to the various effects of anoxia appear in many reviews. Some of the excellent work on the effects of environmental conditions, such as heat and cold and the adaptation to, or protection against, them, is referred to in articles on "Water Metabolism" (I. McQuarrie) and the "Physiological Effects of Heat and Cold" (Allan Hemingway).

Apart from the emergence of war research the *Review* follows lines which have now become familiar. The advances in what may be regarded as the main divisions of physiology—e.g., respiration, digestive system, heart, blood, kidney, energy metabolism, endocrine regulation of metabolism and reproduction—during the past year are surveyed. But the choice of a fresh reviewer makes for an alteration in perspective from year to year—though here might be entered a caveat against the tendency, which shows in more than one instance, to revert to the "card index" type of review. The articles in the early volumes of the series were distinguished by their critical appraisal of the contemporary field and the adoption of a definite point of view by the reviewer. The four articles on neurophysiology—"Electrical Activity of the Brain" (F. A. Gibbs), "Conduction and Synaptic Transmission in the Nervous System" (G. P. McCouch), "Somatic Functions of the Nervous System" (M. A. Kennard), and "Special Senses" (J. M. D. Olmsted)—make a useful symposium despite the unavoidable absence of a fifth review on visceral functions of the nervous system.

Among articles on topics which are not reviewed annually the one on "Peripheral Circulation" (E. M. Landis) is likely to be of interest to clinicians for its sections on capillary permeability and vascular reactions to haemorrhage; while those on "Permeability" (S. C. Brooks) and "Physical Properties of Protoplasm" (W. Seifriz) signify the important role of the physical chemist in elucidating problems of cell physiology. "Exercise" (C. L. Taylor), while covering ground dealt with in some other articles, has a useful survey of "fitness tests."

It is impossible to do more than give an indication of the articles in this *Review* and their trend. To the physiologist who finds it impossible by his own reading to keep pace with the publication of individual papers in every section of the subject, or to the clinician who wishes to keep abreast with the latest advances in physiological knowledge and thought, this compilation is obviously indispensable.

ARTERIAL HYPERTENSION

Arterial Hypertension. Its Diagnosis and Treatment. By Irvine H. Page, M.D., and Arthur Curtis Corcoran, M.D. (Pp. 352; illustrated. $3.75 or 22s. 6d.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

This book on hypertension is by authors whose names are well known for their investigations into experimental hypertension in animals. It is regrettable that the expectations thus aroused are hardly realized, for its quality is decidedly uneven. There is to start with an aetiological classification, but the range of this is so wide that it has no practical value; angina pectoris should hardly find a place. "Neurogenic hypertension" is then described, with an account of a diencephalic syndrome which is unfamiliar. The early stages of essential hypertension are considered to be mainly due to psychoneurosis. Then follow apparently the structural changes; but no very clear line of thought is put forward. The section on physical examination omits any reference to the state of the peripheral arteries, the heart sounds, and the apex beat. The cold pressor test receives a good deal of discussion, which rather outweighs its practical value. Great stress is laid on the retinal examination, and quite rightly, but it is doubtful whether any but the expert ophthalmologist can distinguish the minute differences described. The section on pathology is superficial and the description of arterial diseases obscure; calcification, for instance, is not mentioned. The section on psychotherapy contains a lot of good common-sense advice, but also a good deal of superficial statement. There are considerable chapters on angina pectoris and coronary thrombosis which have little direct bearing on the subject; and the special relevance to hypertension they might have is not brought out. Congestive heart failure is hardly approached in a modern way, for the characteristics of left ventricular failure which are such a feature of hypertension are not given. Alternation of the pulse is not mentioned at all, and the reference to gallop rhythm is inadequate; the description of it as a "cry for help" is surely a misquotation which should refer to alternation. The electrocardiograms are few and appear to be incorrectly described.

The best section, as one might expect, is that on the kidneys, and here is something very well worth reading. All the latest information is clearly set forth in the light of the most recent views of renal physiology. There are some good illustrations. The part played by the kidneys in the later phases of hypertension and the vicious circles set up are described in an interesting and intelligible manner. There follow chapters on treatment, with some discussion of sympathectomy and thiocyanate therapy, but here there is as yet little scope. In their renal experimental work the authors are good, but most of the rest is off the point and unlikely to be of much use to the practitioners for whom the book was written.

ORTHOPAEDICS FOR AUXILIARIES

Fractures and Orthopaedic Surgery for Nurses and Masseuses. By Arthur Naylor, Ch.M., F.R.C.S. With a foreword by Ernest Finch, M.S., F.R.C.S. (Pp. 288; fully illustrated. 16s. plus 7d. postage.) Edinburgh: E. and S. Livingstone. 1945.

This book is written by an examiner in surgery of the General Nursing Council, and may therefore be taken to fill a need in the training of nurses, at any rate from the academic standpoint. It is a short and concise manual of orthopaedic surgery and deviates little from accepted lines, while the text is clear and reading not laborious. Apart from one or two illustrations which are incomplete or inaccurate though qualified in the legends, and one or two which are difficult to understand, the pictures are useful and informative. On the whole the book is up to date, and its main value lies in its brevity, which results from a careful elimination of the rarer orthopaedic conditions and from compression of much that is included.

The set-up is on lines familiar to medical men, but one gains the impression that, from a practical aspect, masseuses and nurses will not find much to help them in their day-to-day handling of patients. Practical points are relatively few and, where elaborated, often more of interest to the house-surgeon than the nurse: for instance, descriptions of methods of plaster application are given, but the more important nursing details of how to observe and treat a patient in plaster receive few lines and little emphasis.

The possession of this book will certainly help the student nurse working in the orthopaedic wards to understand the rationale of the treatment accorded to her patients, and should be of value to her when she comes to face the examiners. By then, no doubt, she will also have learned the practical side of the work from the other members of the orthopaedic team and, in particular, the ward sister.

Notes on Books

Dr. BRUCE WILLIAMSON has revised his little volume, *A Handbook on Diseases of Children*, for a fourth edition (E. and S. Livingstone; 12s. 6d., plus 6d. postage), and recent advances have been included. The quality is "patchy"; sections on the heart, for example, are good, whereas dietetics and nutritional disorders are poorly done. There is a frequent reference to "Grade A milk," and an absence of familiarity with current views on the treatment of such disorders as rickets and scurvy.

The number of diabetic cookery books is legion, but *The Cookery Book for Diabetics* compiled by the Diabetic Association (H. K. Lewis and Co.; 4s.) is rather a special one. In the first place it is compiled by diabetics themselves and with an eye to wartime difficulties and dull food. It is more than a mere collection of recipes, and can claim to be the diabetic's "guide to good living." The first 6 pages give simple but adequate lessons in food values, brightly illustrated with a delightful imp. The bulk of the book is occupied by practical, attractive, and accurate recipes. Indeed they have almost made Prof. Mottram, who writes a foreword, long to be a diabetic. The book contains other practical information and includes Lawrence's 5-gramme food tables. The book in no way encroaches on the physician's province by prescribing diets, but enables any prescription to be followed in an attractive and varied way. All diabetics intelligently interested in their diets—and there are thousands in the country—will find this book very helpful.

Preparations and Appliances

"STERILE" WATER: AN OUT-PATIENT AND SURGERY TECHNIQUE

Dr. ALEX COMFORT writes from the Royal Waterloo Hospital, London, S.E.:

Modern ideas of bacteriology and contemporary nursing training have increased the demand in out-patient clinics for "sterile" water without increasing proportionately the bacteriological criticism to which such water is subjected. The pathogen-sterility of water derived from a corked Winchester, however often it may be renewed, is as a rule experimentally inferior to that of tap water. Water adequately sterilized in flasks for surgically clean procedures such as the washing of syringes and the solution of drugs is usually of limited availability both in surgeries and in small out-patient clinics, because of the wastage brought about by rejecting each flask as it is opened. The amount required in such minor procedures rarely exceeds 5 c.cm., and if each operation involves the opening of a 100-c.cm. flask the space devoted to sterilization must necessarily be large.

The following procedure for the preparation of small quantities of bacteriologically sterile water, without apparatus and in a portable form, may be of interest to those who have to deal with bulk injections under surgery conditions.

A suitable number of ordinary insulin bottles are cleaned, the rubber caps removed, washed, and replaced; each cap is transfixed with a small-bore intradermal needle, and the bottles are immersed at the beginning of the day's work in a bowl of boiling distilled water. They remain there for five minutes, when the bowl is removed and allowed to cool. Filling is automatic and almost complete. The needles are removed, and the cold bottles of sterile water are transferred to the injection tray or to the medical bag. The bottles float inverted if a needle with a sufficiently heavy sleeve is used. The rubber caps seem to resist boiling well, and a single bottle will withstand some dozens of refills. The amount in each bottle suffices for washing and filling a 2-c.cm. syringe, and the entire batch is reboiled daily. The method has worked well in practice.

Rh INCOMPATIBILITY AS A CAUSE OF MENTAL DEFICIENCY

It has long been known that in a small proportion of infants dying of erythroblastosis foetalis cerebral changes are to be found. To these the name "kernicterus" was given by Schmorl,[1] who found 6 instances in 120 cases of jaundice of the newborn coming to necropsy. Although the staining and damage may be widely spread throughout the cerebral and cerebellar cortexes it is the basal ganglia which tend to be specially affected. Accordingly it was not surprising that it should be discovered that among children who survived were to be found occasional instances of severe mental defect associated particularly with extrapyramidal rigidity and athetosis. The relationship to the pathological entity "kernicterus" was confirmed by Zimmerman and Yannet[2] in a detailed study on a child who died at the age of 3. Thus it may be anticipated that among mental defectives there will occasionally be found individuals who have a history of severe jaundice at birth, who are Rh-positive, and who present evidence of involvement of the basal ganglia. It is, however, a very rare picture. Yannet and Lieberman[3] found only a single instance among 1,200 admissions to a colony for mental defectives.

If this were all, the practical importance of Rh incompatibility as a cause of mental deficiency would be slight indeed. But Yannet and Lieberman are able to show that this is far from being the complete story. Zimmerman and Yannet[2 4] had previously observed that among their own families, and in those reported in the literature, were to be found instances of severe mental retardation without evidence of the involvement of the basal ganglia. In the second place certain children identified post mortem as cases of kernicterus had suffered from so slight a jaundice that it had been considered physiological. Accordingly Yannet and Lieberman set out to discover whether there was any evidence to show that Rh incompatibility might be responsible for a proportion of ordinary low-grade mental deficiency. They determined the Rh blood group of 109 idiot and imbecile children, together with that of their mothers: 53 of the children fell into various special groups (mongols, 23; spastic diplegia, 13; post-natal infection, 8; birth trauma, 4; cranial anomalies, 3; cerebellar ataxia, 1; amaurotic idiocy, 1). Of these, only 4 proved to be Rh-positive with Rh-negative mothers, which is close to the expectation in a random sample of the general population. On the other hand, the 56 undifferentiated idiots and imbeciles included no fewer than 11 who were Rh-positive with Rh-negative mothers. If we were to draw a random sample of 56 mothers and children from the general population, the expected number, accepting the proportion of Rh-negative persons as 15%, would be 5.15—less than half the number observed. So large a discrepancy would not occur by chance oftener than once in about 75 trials. This calculation, moreover, does not take into account the fact that the deviation from expectation is in the direction demanded by hypothesis. This finding is the first indication, and a very strong one, that a far from negligible proportion of low-grade defectives owe their condition to Rh incompatibility. Taken in conjunction with a hypothesis firmly grounded on pathological and clinical observations, it seems out of the question that the excess could be anything other than an indication of cause and effect. Some children, therefore, who recover from their pernicious jaundice, or who may not display pernicious jaundice at all, become mental defectives of ordinary undifferentiated type because of damage to their brains owing to development of anti-Rh factors in their mother's blood. These observations have been speedily repeated by Snyder, Schonfeld and Offerman.[5] They confirm Yannet and Lieberman's findings, for 11 out of 68 similar undifferentiated defectives proved to be Rh-positive with Rh-negative mothers. Adding the two series together, the number is 22 out of 124. The expected number in a random sample of 124 is 11.40. The odds against so big a difference as this arising by the accidents of sampling are nearly 600 to 1, again without allowing for the fact that the deviation is in the expected direction. The evidence in favour of the hypothesis is thus very strong, but the figures are not yet sufficient to allow any close estimate to be made as to how much mental deficiency is due to this cause. Should further work reveal a figure similar to that indicated in these first series, then Rh incompatibility would be about half as important numerically as mongolism as a cause of mental deficiency among institutional defectives.

Before this new discovery was made Haldane, in a paper discussed in an annotation in these columns,[6] pointed out that erythroblastosis foetalis is responsible for more deaths than is any other inherited condition—perhaps for more than all of them put together. Rh incompatibility therefore raises a problem in negative eugenics second to no other. We suggested in our annotation that this eugenic problem might be evaded in the future by timely recognition followed by prompt treatment of the newborn child. Prof. Leonard Parsons[7] suggested we were unduly optimistic. He pointed out that much damage may perhaps occur before birth, instancing particularly kernicterus. The present findings among mental defectives add notably to the known evil effects of Rh incompatibility and emphasize the doubt whether successful treatment at birth may not sometimes merely substitute a living idiot for a dead baby, and this apart from the fact that even more frequently there may be no severe jaundice at all. It seems futile to suggest that the 15% of Rh-negative women should have 85% of the male population barred to them; yet the dangers are relatively great. It is clear that more research is urgently called for along a number of different lines. In particular, it is much to be hoped that Yannet and

Lieberman's work will be followed up on a large scale. It could then be determined how much low-grade mental deficiency is due to Rh incompatibility. Intensive work could be done on mothers and defective children when the former proved to be Rh-negative and the latter Rh-positive; such studies would include family investigations and inquiries regarding previous pregnancies; the attempt could be made to distinguish clinically those defectives who owe their mental state to maternal anti-Rh immune bodies. The problems are urgent, while the resources of a single colony are insufficient to provide enough material within a reasonable time. Clearly there is need for co-operative research by many such institutions, in collaboration with the experts of a serological laboratory, and we are pleased to record in this week's correspondence columns an offer to collaborate from Drs. R. R. Race and A. E. Mourant, of the Galton Laboratory Serum Unit at Cambridge.

EPIDEMIC DIARRHOEA

Although "summer diarrhoea" has ceased to occur in great epidemic waves and the annual deaths from diarrhoea in children under 2 years of age have fallen in half a century from 40,000 to 3,000, yet more young children die of this disease to-day than from any other infection except pneumonia. It is accordingly a cause of considerable anxiety to those concerned with the public health, the more so as there is evidence of an increased incidence during the war years, and large-scale epidemics have recently broken out in at least two cities. Epidemiologically, infantile gastro-enteritis is characterized by its preponderance among artificially fed infants in poor-class urban areas; aetiologically, no bacterium or virus has yet been discovered which can be accepted as the specific cause of the infection. Indeed, many expert observers regard infantile enteritis as a non-specific disease secondary to parenteral, and particularly upper respiratory, infection. Others believe that the primary agent is a virus which has its entry into the oropharynx, predisposing, like the viruses of measles and influenza, to secondary complications such as otitis media; others, again, hold that otitis media is the primary infection leading to secondary diarrhoea and vomiting.

Among recent contributions to the solution of this complex problem is the report by Buddingh and Dodd[1] of a virus isolated from the mouths of young children with stomatitis and diarrhoea. The first symptoms in this syndrome, which appears most commonly in infants under 6 months of age, are a sore mouth, refusal of feeds, fretfulness, but no fever. The lips and anterior margin and under surface of the tongue are fiery red, and fine vesicles may be noted on the affected areas and on the gums. Later the mucous membrane of the tongue desquamates and leaves a raw ulcerated surface. Diarrhoea but not vomiting occurred in about one-third of the cases; stools were frequent and contained large quantities of mucus, sometimes flecked with fresh blood. The disease is infectious, with an incubation period of 2 to 3 days and a rather mild course of 3 to 10 days; there may be relapses. Aetiologically it is distinct from herpetic stomatitis; specific antibodies appeared in the blood of affected children.

It may be noted that an epidemic form of nausea, diarrhoea, and vomiting among adults, often diagnosed as "gastric flu," has in recent years been observed both here and in the U.S.A. Reimann and his colleagues[2] have given a detailed account of this type of infection, which they believe may be due to an air-borne enterotropic virus. Most commonly the first complaint is of epigastric discomfort and nausea (like sea-sickness), followed in a few hours by vomiting. Diarrhoea, if it occurs, is characterized by considerable abdominal discomfort. There is only slight fever or none at all, and the symptoms clear up in 1 to 2 days. Very few patients feel ill enough to go to bed or to call in a doctor. The syndrome is similar to that described in this *Journal* two years ago by Bradley,[3] except that diarrhoea was not prominent in the outbreaks he recorded. Hyperaemic tongue papillae and injected fauces, like the early stages of a streptococcal throat infection, were, however, commonly noted among his cases. Although there is apparently no special seasonal incidence for this infection, many of the recorded outbreaks occurred in late autumn. Attempts to isolate a specific bacterium or virus have failed, but Reimann and his colleagues reported some success in the transfer of infection to human volunteers who inhaled the sprayed filtered nasopharyngeal washings or stools of affected patients.

Claims that the much more serious gastro-enteritis of infants is due to infection by some abnormal member of the coliform family are made from time to time, and Sevitt[4] in a recent investigation of some 400 cases in Dublin has been impressed with the frequency of both *proteus* and paracolon bacilli in the faeces of affected infants compared with normal control cases. Feeding experiments in kittens with paracolon strains resulted in entero-colitis in a high proportion of the animals. These studies, correlated with the recent summer outbreaks and the greater prevalence of flies, point again to a primary intestinal food-borne infection, and, although evidence of acute inflammatory reaction in the gut is usually absent, the frequency of liver damage in cases of infantile enteritis suggests absorption of toxic substances from the bowel. Another point in favour of an intestinal aetiology in one form of the infection is the apparently beneficial effect of sulphaguanidine in neonatal diarrhoea, as originally claimed by Henderson[5] and lately corroborated by Campbell[6] in outbreaks in maternity units in Melbourne. The newer intestinal antiseptics deserve a more extensive and controlled trial in the enteritis of older infants.

Careful bacteriological examination of the faeces or rectal swab on modern selective media should always be carried out in cases of infantile enteritis, and the stools of children over 1 year of age should be examined directly for *Giardia*, which has been incriminated as a cause of subacute diarrhoeal attacks.[7] Yet American findings agree with experience in this country that specific bacterial pathogens are rarely found among cases of infantile diarrhoea in temperate climates. Thus, while Hardy and Watt[8] found dysentery organisms in 63% of the severe cases and in 33% of mild disorders among infants up to 6 months of age in New Mexico and Georgia, only 7% of affected infants of the same age group in New York gave positive findings. But if the aetiology of this non-specific enteritis is still obscure its prophylaxis is possible if ways and means can be found for working-class mothers to breast-feed their babies for the first six months of life. An adequate diet during pregnancy and lactation together with helpful advice and education will largely solve this problem. Fortunately, the Government is beginning to realize that the "nutrition of the pregnant and lactating poor should be a first charge on the resources of a Christian State."

GRAFTING FOR BURNS OF THE EYE

The use of buccal mucous membrane grafts for the treatment of cicatricial conditions affecting the conjunctival sac is well known, but their use for more acute conditions of burns of the conjunctiva is not so widely appreciated. Denig[9] in 1920 advocated the principle, to which he had referred in 1912, of providing an epithelial covering for granulating burnt conjunctiva rather than allowing it to heal without surgical intervention. Again in 1929[10] he discussed the use of circumcorneal buccal mucous membrane grafts in extensive conjunctival burns, and in all cases of ammonia burns of the eye, claiming that in many it prevented the severe complications that would normally follow such injury. The technique was to employ two or more grafts suitably shaped to replace the burnt conjunctiva around the cornea, secured to the sclera by interrupted catgut sutures, which were removed in 10 to 12 days. O'Connor[11] in 1933 emphasized the seriousness of burns due to ammonia, and mentioned the delayed effect which becomes evident in a week or ten days. He claimed that early grafting diminished scar-tissue formation, prevented symblepharon, and had a beneficial effect on corneal nutrition. For burns of the palpebral conjunctiva he placed the graft on a small thin stent mould and sutured it in place, care being taken that the stent should not be in contact with the cornea; if that was not possible he sutured the graft in place without using a mould. Circumcorneal grafts were used for burns affecting the bulbar conjunctiva. There were many technical difficulties and failures, but there was also the possibility of great benefit for many severe burns of the eye. In 1938 Denig[12] described the impairment of the limbal circulation in ocular burns which led to the formation of a secondary opacity in the cornea, and showed how this was preceded by infiltration of the sclera, which in experimental work was shown to be quite apparent in 48 hours and advanced in 5 or 6 days. This damage could be prevented if grafting was performed very early—say, one hour after the injury. It was also considerably less than it would otherwise have been if the grafting was done in 24 hours. He found that the effect of an alkali was greater than that of an acid, and that ammonia was particularly damaging. If because of the severity of the burn or too much delay the sclera is necrosed the graft will not take. In general it was found best to operate within six hours of the injury, but even if delayed longer than this it was better than not to operate at all. Localized damaged patches of bulbar conjunctiva could be removed and replaced by a graft sutured to the sclera, and more extensive transplants according to the extent of the damage. He quoted 82% success by operating in this way and a higher percentage in those operated on within six hours. It was found that blindness was three times more frequent after conservative treatment than after operation. He stated that all cases with corneal damage accompanying a conjunctival burn should be operated on, and that conservative treatment should be confined to first-degree burns without corneal damage unless they were caused by alkali or liquid gas or halogens.

Siegel[13] has classified conjunctival burns as follows: (1) simple conjunctivitis; (2) with profuse exudate; (3) with necrosis, emphasizing the potential danger to the cornea caused by blockage of the perilimbal blood vessels and lymphatics. Particularly grave are those cases in which the sclera is of a porcelain-white appearance. He advocated early grafting in all cases in which damage to the perilimbal circulation might be suspected, and the destruction of vascular supply to a part or the whole of the cornea was his criterion for grafting. Various grafts have been tried. Probably the best, when available, is autogenous conjunctiva, labial mucous membrane being the next best. Buccal or labial mucous membrane retains its rosy colour and thickness, but at a later stage the cosmetic result can be improved to some extent by operation if required. The graft can be removed by means of a cataract knife, and very fine silk or catgut is used to suture it in place, the silk sutures being removed in a week; until then the eye is kept closed with a pad and sterile petrolatum applied.

The results seem to show that treatment of this kind improves the chances of retaining a useful eye after severe conjunctival burns, and that less severe cases are benefited by such treatment. It is only too well known that disasters can befall an eye after chemical burns, and it is disheartening to watch such a case and see the conjunctiva shrink up and the cornea become cloudy and ulcerated in course of time—resulting in a useless eye, or an eye with extensively adherent eyelids which render the eye useless. If some mitigation of these ill effects is possible by any form of treatment then it should be given a trial, and the experience of those who have tried early grafting with buccal mucous membrane after removal of damaged conjunctiva indicates that this is a line of treatment that should be more widely recognized. The practical application of these principles is by no means easy, and there are technical difficulties. The operation may have to be carried out when the patient is still in much pain; swelling of the lids may be considerable and will interfere with facility of operation. There is, however, so much at stake that a patient should be given whatever chance there is of retaining useful vision and of diminishing the seriousness of ensuing complications. The method of treatment by early grafting of buccal mucous membrane promises to be of benefit in this way.

SULPHONAMIDE CHEMOPROPHYLAXIS IN WOUNDS

During a period which began rather before the war and extended well into it sulphonamides were regarded as the mainstay, apart from adequate surgical treatment, in preventing wound infection. Armies provided their soldiers with packets of sulphanilamide to shake into their wounds, and even with tablets to swallow thereafter. Proflavine and then penicillin came in in the later stages of the war, and we shall probably never know how much good was really done by the earlier method; for many reasons this war has been a less fertile opportunity of studying wound infections than the last. Meanwhile a group of investigators in the U.S.A., officially instructed to ascertain the truth in this matter for the benefit of further casualties, have analysed the results of sulphonamide prophylaxis in a large series of civilian wounds. The report on this investigation by F. L. Meleney[1] deals with a total of 2,191 cases, of which 926 were wounds of soft parts, 674 compound fractures, and 591 burns. They were treated at nine different centres, where records were kept in a uniform manner for subsequent analysis as a whole. No uniform system of sulphonamide treatment was apparently adopted, the cases being divided into those which received it in any form, whether local or general, and those which did not. The number of control cases was about equal to the treated among burns, but only one-third in the two other categories; and some difficulty seems to have been found in providing adequate controls, particularly at centres dealing with serious industrial accidents where sulphonamide prophylaxis had come to be regarded as a necessity. There is also evidence that the treated cases were rather more severe, exhibiting in a higher percentage those features tending to the establishment of infection. It is nevertheless thought that the controls form a satisfactory basis for comparison. These extensive data are analysed and cross-tabulated in almost every possible way in a total of forty-six tables. From this analysis the dependence of the frequency of infection on such factors as the extent of tissue damage and of contamination emerges clearly. On the other hand, it affords no evidence whatever that sulphonamide treatment reduced the frequency of infection; the controls on the whole fared somewhat better from this point of view. This conclusion was evidently unexpected, and has been accepted with regret. It is fully recognized that sulphonamides may prevent so extensive a spread of infection as to endanger life: the actual mortality from sepsis in this series was very low, thanks presumably to the initial administration in the treated cases, and to subsequent administration for definite indications in the controls. What sulphonamides will not do, according to these results, is to reduce liability to either trivial or serious infection of the wound itself. Routine prophylactic administration is therefore wasteful, and, owing to the toxic reactions that sometimes follow, positively harmful.

The wheel has certainly turned full circle since the high hopes of five years ago. Perhaps the last word on the subject has not been said; there are certain objections to this method of arriving at the truth. Great numbers do not compensate for lack of uniformity in material, and those who have the opportunity should repeat this comparison under more closely controlled conditions. There is, after all, clear experimental evidence that sulphonamides will check the activities at least of certain bacteria in wounds, and, if corresponding results are not observed in the clinical field, there must be reasons for it which have now to be ascertained.

THE PHYSIOLOGY OF EMOTION

Emotion is thought to have an emergency value. Its physiological effects are generally held, according to the views of W. B. Cannon, to be such as to put the body into a state to deal efficiently with a situation. In fear and rage the best conditions are provided for supreme muscular effort, in part, by the secretion of adrenaline. Cannon's views have now been criticized by M. B. Arnold.[2] She points out that the results of fear and of adrenaline injections in animals are frequently to produce a state of frozen immobility, and occasionally prostration. Adrenaline is supposed to cause an increase in muscular contraction, in blood flow to the limbs, and in the rate of the heart-beat, lysis of liver glycogen, contraction of the spleen, and a relative polycythaemia. Arnold gives evidence for denying some of these effects, for regarding others as secondary parasympathetic reactions, and for reinterpreting the experiments from which they have been deduced. The effect of a stimulus on the organism has to be distinguished from the organism's reaction to that effect. The classical theory of reciprocal innervation does not hold entirely good, and must be replaced by a theory of action and reaction between the sympathetic and parasympathetic systems. The effects of fear and rage are opposite: in the one somatic activity is regularly reduced, in the other increased. Fear may be useful to the organism not because it prepares for action but because it enjoins caution.

Arnold believes that there are at least three different physiological states corresponding to three different emotions: fear, with predominantly sympathetic excitation; anger, with strong parasympathetic excitation; and excitement, or elation, with moderate parasympathetic activity. The startle reaction and explosive, or epileptoid, behaviour are different again, and correspond to a "functional decortication"; in them an immediate response is obtained via the cholinergic mechanism, without conscious evaluation. Neither anger nor fear has an emergency function; the optimal state of the organism is in a moderate degree of activity of the cholinergic mechanism.

Some of Arnold's arguments have a polemic ring; and it is difficult to believe that the immediate response of the organism to an emergency situation is not controlled by physiological mechanisms which in the past have been adaptive and had a survival value. Nevertheless she makes it clear that many current and accepted views on the physiology of the emotions are over-simplified and may need reconsideration. Whatever the evolutionary value of fear and rage in our brutish ancestors, they have little survival value in such emergency situations as arise in warfare to-day. The cool head stands the best chance in both aggressive and evasive action.

THE NEW MINISTER OF HEALTH

Among the elderly men whom Mr. Attlee has chosen for his Administration the new Minister of Health, Mr. Aneurin Bevan, stands out by reason of his age: he was described by one newspaper as "the baby of the Cabinet." He has represented the Ebbw Vale Division of Monmouthshire since 1929, and during this time has built up a reputation as a back-bench critic with a formidable tongue and destructive wit, qualities also used to effect in the paper with which he has recently been associated—the *Tribune*. The son of a coal-miner, Mr. Bevan himself went into the mines after leaving school at the age of 13. He was prominent in the councils of the South Wales Miners' Federation, and was miners' disputes agent in 1926. Since 1928 he has been a county councillor for Monmouthshire. He was expelled from the Labour Party in 1939 because he associated himself with the "Popular Front" movement, but nine months after this expulsion was readmitted to membership. Now, at the age of 47, he becomes the fifth Minister of Health this country has had since the beginning of the war.

Mr. Attlee has appointed Viscount Addison to be Secretary for the Dominions, and he also becomes Leader of the House of Lords. Dr. Edith Summerskill is to be Parliamentary Secretary to the Ministry of Food.

THE RETURN OF ODYSSEUS

THE PROBLEM OF MARITAL INFIDELITY FOR THE REPATRIATE

BY

ALFRED TORRIE, M.B.

Lieut.-Col., R.A.M.C.; Army Psychiatrist

The returning soldier from a prisoner-of-war camp or from an oversea theatre of war may have many difficulties to solve, and often the greatest of these is the problem of marital infidelity. Most repatriates are able to adjust satisfactorily, but some require help.

It will be remembered that Homer described very accurately the hopes and fears of a soldier, Odysseus, who was both a prisoner of war and a repatriate. The epic poems telling his story are symbolically true and eternally applicable. Odysseus (Ulysses) when he was abroad on his campaigns had doubts of his wife's fidelity and visualized her surrounded by many suitors. His fears were counteracted by his wish that she would defer continually her yielding to their persistence. This she contrived by the trick of promising her favour when her tapestry reached completion; but each night she undid the work of the day. On his return to his own country he was in doubt whether he would be accepted and acceptable, and so he made himself known to devoted servants of whose loyalty there was no question. In order to observe without declaring his identity he dressed himself in the garments of a peasant, and when he was sure of his ground assumed his proper raiment and wooed and won his wife again.

The moral to be drawn from this is that the returning soldier may be full of fears and hopes and that his main concern is to be both loved and lovable.

The Problem of Marital Infidelity

Of 100 repatriates from prisoner-of-war camps in Germany and Italy treated in a psychiatric unit at home 24 had as the main precipitating factor in their neurosis marital disharmony. Their symptoms were those usually found in reactive anxiety states: depression, sleeplessness, irritability, restlessness, somatic disturbances of various kinds, outbursts of aggressiveness, attacks of weeping, and a feeling of inadequacy and inferiority alternating with a paranoid attitude towards their wives. This latter attitude in many instances began during their imprisonment, often as a result of infrequency of letters and sometimes following the receipt of news by a fellow prisoner that his wife was seeking a divorce. The communal gloom that occurred in a camp when such a letter was received was graphically described by one intelligent and observant patient. The opposite feeling is well pictured by P. H. Newman (1944) in his article on the prisoner-of-war mentality. This writer describes a lecture delivered by a recently captured R.A.F. officer who, after giving a picture of wartime life in England, added: "And, boys, the girls still love you." He adds that this comment evoked an immediate and marked response in the audience, in contrast to their apathy during the lecture.

I have recently seen an officer patient who had to deal with many welfare problems arising from marital infidelity, and this work had such an effect on him that he began to construe the most innocent remarks in his wife's letters as evidence of the diversion of her affection elsewhere.

Aetiological Factors in Marital Disharmony.—These were elicited by interviewing the wives of most of the patients in addition to making a detailed psychiatric investigation of the repatriate.

The Problem of Penelope

It seems to me that war and its attendant destructiveness are fundamentally foreign to the creative aspect of a woman's personality. Not only may it remove the presence and support of the husband, but at the same time she is exposed to unusual dangers, difficulties, and responsibilities. The long absence of her husband may in time cause her to accept the offer of sympathy, understanding, and support readily given in many instances by a soldier or civilian who has a complementary need to care for and protect. This may be the innocent beginning of a situation which ends in infidelity. Some wives had been evacuated from danger to new environments in safe areas, with the new danger of boredom, while others remained at home in an atmosphere of heightened emotional tension during enemy activity. New ties were formed in an atmosphere either of common danger or of boredom. The repatriate cannot enter into this new way of life, even in retrospect; nor can the wife fully appreciate the nature of prison-camp life. Few repatriates realize the many difficulties their wives have had as a result of wartime restrictions. In addition there is the need for male control and guidance in homes where there are children. The total management of the home causes to devolve on the woman many tasks formerly undertaken by the husband. The advent of a helpful male friend may initiate a train of events perhaps ending in marital infidelity, which may be excused by the common belief held by many women that, anyway, men are unfaithful. It need hardly be said that the sudden cessation of regular sex life for a woman with no adequate sublimatory channels may lead to difficulties. A further obvious factor is that the husband may have always been inadequate from the physical and other points of view, and a more satisfying partner may appear during his absence. Homosexual regression in some cases is a factor that may be found in either wife or husband. What is most difficult for the husband to understand is that the physical infidelity of his wife may not constitute a supplanting of him in her affection.

The Problem of Ulysses

Many prisoners of war fear that their experiences may have caused both physical and mental deterioration. They have fears of loss of potency, and these fears may indeed bring it about. Impotence may also occur as a result of the guilt engendered by the fusion of sexuality with aggressiveness. There may be feelings of guilt, inadequacy, and inferiority due to homosexual regression and as a reaction to capture. In the camp the prisoner has highly coloured fantasies of his return home and of his reception. All these factors are difficult for the wife to understand, as is the whole picture of his life in camp. The dream of beginning all over again and securing a home is often rudely shattered by the many difficulties besetting the path of young married couples to-day. The sense of inadequacy is increased by these frustrations. Guilt over capture leads to a feeling that, being no longer a fighting soldier and therefore an unheroic figure in his own eyes, he may be less lovable in the eyes of his wife and family. In parenthesis it may be said that the problem of explaining the capture of the father to children whose games are all of battle must be a very difficult one for the wife. In the neurotic repatriate, paranoid feelings towards all and sundry are often quite strong. He may feel that his capture is due to bad leadership in the field and at home, and that he is the innocent victim of this. His attitude towards his wife is coloured by these feelings, and often also by poison-pen letters, and he is less willing to understand any wartime friendship. On his return he adopts the attitude of Othello, and disharmony quickly follows. His neurotic dependency may have been increased by his experiences, and he is unable on his return to give to his wife the care and support which she rightly expects. Lack of confidence in ability to regain previous skill at work further diminishes their feeling of adequacy as husbands and breadwinners.

Treatment

It must be said at the outset that separation and divorce should be the last solution, especially where there are children. The patient's neurosis is treated on ordinary lines until he is in a fit state mentally to face the problem of his marital unhappiness. In most cases I sent for the wives and interviewed them. In only a few did I discover that the wife no longer wished to live with her husband. These marriages were based on very inadequate foundations, and generally after a brief acquaintance. In most of these cases there were no children, and reconciliation was impossible. In the majority, however, the wives wished to start again, and were convinced that they wanted only their husbands. This knowledge was the most effective weapon in treatment, and once the patient was convinced of its truth reconciliation was possible. After the wife had been interviewed the patient was brought in and every aspect of the problem discussed fully and frankly by all three of us. The tendency on the part of the husband to use the past as a weapon in any later disagreement should be pointed out. Any physical marital difficulties must be rectified.

Summary

Out of 100 repatriates in a psychiatric unit at home 24 had a neurosis largely precipitated by marital infidelity.

The factors leading to this are discussed from the woman's point of view.

The attitude of mind of the repatriate is described.

Treatment must include an adequate interview with the wife and a conference between the married couple and the psychiatrist.

CONFERENCE ON PUBLIC HEALTH

The County Borough Group of the Society of Medical Officers of Health held its annual meeting from July 13 to 15 at Wadham College, Oxford, under the presidency of Dr. A. Massey. Among the members present were Sir Wilson Jameson and Dr. J. A. Charles of the Ministry of Health, and the guests at the inaugural dinner held in the Hall at Wadham included the Mayor of Oxford (Councillor R. P. Capel), Sir Farquhar Buzzard, and Prof. J. A. Ryle. On July 14 the Mayor gave an official reception for members at the town hall. There was a special demonstration by Mr. H. Cotton of the statistical methods and machines in use at the Institute of Social Medicine, Oxford. Dr. R. H. H. Jolly was elected president of the Group for the coming year, while the secretary is Dr. J. Greenwood Wilson.

Among the addresses given at the conference was one by Prof. J. A. RYLE, on problems and prospects of the Institute of Social Medicine. He emphasized the importance of close association between an academic department such as that under his direction and those more practically concerned with public health. He compared the technique of the specific social medical survey with that of more orthodox clinical studies and stressed the need for social experiments in varying communities. He called attention particularly to the work of the Bureau of Health and Sickness Records set up in Oxford with the financial aid of the Nuffield Provincial Hospitals Trust.

Dr. ROBERT SUTHERLAND, in a paper on the work of the Central Council for Health Education, said its task was to make the community dissatisfied with everything except the best in communal and individual health. This meant not only spreading knowledge but teaching the community how to behave so as to reduce the impact of forces unfavourable to health. Health education was not simply a question of propaganda but a way of living. The Central Council's long-term policy was to influence the individual not only to make the best of his environment but to modify it to his advantage.

Dr. J. GREENWOOD WILSON, discussing post-war housing, said that in this country there was no single co-ordinating influence over the many groups of persons interested in housing problems. There were between forty and fifty study committees of the different Ministries, and the Government's Building Research Station had an honourable record of research into the structural efficiency of building materials. In fact, however, little had been done to publish the results of housing research. It was time to fill some of the gaps in our knowledge of desirable housing arrangements. Exhibitions of the right kind should be a routine part of the national programme of health education, and it was his object to incite the medical officer of health to a new interest in housing and to approach the problem from the point of view of a biologist, studying the effects of housing conditions on the health of humanity. Dr. G. C. WILLIAMS, M.O.H. for Oxford, referring to the application of the new Education Act, said routine school medical inspection had been described as the cornerstone of the school medical service, but the shortage of doctors had shaken it. Intermediate inspections, at any rate, might well be done by the best type of school nurse. On the question of finance he pointed out that if the local education authority had to accept financial responsibility for every child treated in hospital his city would be involved in an additional rate of 2d. in the pound. In the discussion which followed it was suggested that hospital contributory schemes would, as one result of the new Act, repudiate liability for children's hospital costs, and this would necessitate a financial agreement between health and educational committees.

LA PRESSE MEDICALE

A FRANCO-GERMAN INCIDENT

We are already beginning to get a glimpse of what our French colleagues had to suffer during German occupation. One example of what they had to endure is shown in the following note which the Editor of *La Presse Médicale* had to publish in the issue of March 13, 1943, which has just reached us:

> *En exécution des mesures de Concentration Industrielle ordonnées par le chef du Gruppe-Presse de la Propaganda-Abteilung-Militaerbefehlshaber in Frankreich, notre journal doit changer d'Imprimerie. Nous nous excusons auprès de nos abonnés si certains retards se produisent dans l'envoi des numéros.*

Having been forced by the German propaganda department to change the printer, *La Presse Médicale* nine months later had to reduce its issues to two monthly. This was "*Conformément aux décisions prises par la Corporation nationale de la Presse française, en accord avec le Chef du Gruppe-Presse, Propaganda Abteilung in Frankreich. . . .*"

Nine months after this, on the cover of the issue of Nov. 11, 1944, the Editor was able to announce its deliverance from its German press masters in the following message:

> *La Presse Médicale reparaît après une interruption de près de trois mois; elle désire saluer, dès ce premier numéro, la libération de Paris et celle de la presque totalité de la France.*
>
> *Tous les autres événements pâlissent à côté de cette simple mention et notre journal n'accepterait pas de reprendre sa vie normale sans que soit dite d'abord dans ses colonnes la reconnaissance de tous les fils de France aux rénovateurs de sa liberté.*
>
> *Notre première pensée se dirige vers ceux qui ont donné ou qui donnent encore leur vie à la Patrie, soit au delà des mers, soit sur le sol natal,—vers ceux qui, obscurément, prisonniers, déportés, ou les armes à la main, ont souffert et lutté,—vers ceux des membres du corps médical qui ont, dans une résistance déclarée ou occulte, aidé nos combattants et avec eux risqué ou sacrifie leur existence.*
>
> *Et dans ce jour où, après la libération, la victoire se dessine, nous voulons affirmer notre communion avec eux tous et notre foi dans la patrie.*

As a footnote to this incident in the history of medical journalism we would add one comment: Vive *La Presse Médicale*!

BEIT MEMORIAL FELLOWSHIPS

The Trustees of the Beit Memorial Fellowships for Medical Research in their annual report for the year 1944–5 record with regret the death of Lord Onslow, who had served as a Trustee since 1928. They also record the great loss that they and the whole of medicine have suffered in the death of Sir Thomas Lewis, F.R.S., who was the first person to be elected a Beit Fellow when the Fellowships were instituted in 1910, and was a member of the Advisory Board at the time of his death. The resignations from the Advisory Board of Sir Henry Dale, P.R.S., and Sir John Ledingham, F.R.S. (who has since died), were accepted with regret, and Dr. C. H. Andrewes, F.R.S., Prof. J. H. Gaddum, F.R.S., and Prof. H. Himsworth, F.R.C.P., have been elected to fill the vacancies. The Trustees note with pleasure the election this year of Dr. H. D. Kay (Fellow 1922–8) and Miss M. Stephenson (Fellow 1914 and 1920–2) to the Fellowship of the Royal Society.

The following elections have been made:

Fourth-year Fellowship (£500 a year).—F. W. Landgrebe, D.Sc.: to continue the study of the physiology of melanophore hormone and the nutritional factor responsible for the lethal effect of thiourea in rats; at the Materia Medica Department, Aberdeen.

Junior Fellowships (£400 a year).—J. F. A. McManus, M.D. (Canada): to study the topography of lipine distribution in normal and pathological tissues; at the Department of Zoology and Comparative Anatomy, Oxford. O. L. Thomas, M.B., Ch.B., M.P.S. (New Zealand): to study thyroid activity, the pituitary phenomena found experimentally in thyro-activated animals, and the problem of neurosecretion; at the Anatomy Department, Oxford.

Reports of Societies

CLINICAL PATHOLOGISTS IN SESSION

The Association of Clinical Pathologists held its summer meeting at the School of Hygiene and Tropical Medicine on July 20 and 21. Dr. W. H. **Grace** opened the proceedings on the first day with a paper on "The Dead Infant," in which he discussed the pathologist's difficulties when post-mortem signs were limited. Dr. G. R. **Osborn**, in a paper on the action of thiouracil on goitres, demonstrated the changes seen in goitres removed after treatment with this drug, and pointed out the dangers of mistaking for malignant changes the hyperchromatic cells and the dense, hard, nodular areas of the goitre. He agreed that thiouracil was now the best pre-operative treatment for diffuse toxic goitre. Dr. M. O. **Skelton** described a case of fatal tracheo-bronchial diphtheria in an infant of 5 weeks, and stressed the difficulty of isolating the organism, especially in the presence of a heavy overgrowth of *Staph. aureus*. Dr. E. N. **Davey**'s paper on the allergic state, in which he described the findings in 120 allergic children, was followed by a good discussion on the value of skin tests. Dr. **Gardner** completed the day's session with a paper on the laboratory diagnosis of Weil's disease, with special reference to agglutination tests. He had investigated 900 cases of suspected Weil's disease and had found 150 cases positive. From his records it was clear that jaundice was not always present, and that the prognosis was probably better in the non-icteric case. Mortality differed with age; in a series of cases 50% were fatal in old people and only 5% in young people, with an over-all mortality of 12%. He hoped that, since penicillin showed such promise in the treatment of the disease, the diagnosis would be more readily made, using standard formalized suspensions.

Saturday morning's session began with a paper by Squad. Ldr. E. M. **Darmady** on the traumatic uraemia syndrome, Dr. **Allott** and Dr. **Joan Ross**, who referred to cases she had collected from the battle areas, speaking in the subsequent discussion. Prof. J. H. **Dible**'s subject was the pathology of infective hepatitis with special reference to hepatic biopsy, while Major C. E. **van Rooyen** discussed viruses and described rickettsial agglutination tests in the diagnosis of epidemic and murine typhus. Dr. K. B. **Rogers** demonstrated a new technique for controlling temperature in the sedimentation test, and showed the discrepancies which occurred as a result of temperature variations. Other papers were by Dr. R. E. O. **Williams** on the value of preliminary fluid culture for the isolation of pyogenic cocci when a larger yield was desired, and by Dr. **Sladden** on the routine examination for diphtheria, using a tellurite Loeffler medium, which, he claimed, was a simple and effective substitute for the elaborate media now in use. The meeting ended with a contribution from Dr. H. N. **Stafford**, coroner for West London, on "The Corpse, the Pathologist, and the Coroner," in which he discussed the duties and limitations of the pathologist in regard to the coroner. There were a number of demonstrations during the two days, which were well attended.

An interesting series of meetings has been organized in Germany by Lieut.-Col. M. Markowe, R.A.M.C., and Major W. C. Harvey, R.A.M.C (in peacetime assistant M.Os.H. for Ipswich and Southgate, respectively) for Army Hygiene Officers attached to 1 Corps District. The morning session of each was devoted to a review of local problems as they affect military hygiene officers and Military Government public health officers, and the afternoon to discussion of general public health problems, including the latest developments in civil legislation and procedure. At the last conference a paper on the school medical service was read by Major Grundy, R.A.M.C. (M.O.H. for Southall), and a discussion followed which was as varied as it was vigorous. Most of the hygiene officers who attended are members of the Society of Medical Officers of Health, and it is felt that these meetings if continued will, through the contact thus established, keep them in touch with their peacetime duties, and serve to remind them of the group meetings of their Society, to which they look forward when their work in Germany is done.

P. Hogg and C. D. Bradley (*J. Pediat.*, 1945, **26**, 407) record a case of pneumococcal meningitis with recovery in a female newborn infant who was given sulphadiazine. This is the third case with recovery which has been recorded.

Correspondence

Rh Factor and Mental Deficiency

Sir,—It has been established beyond doubt that Rh blood group incompatibility is responsible for a considerable proportion of low-grade mental deficiency. To determine the extent of this responsibility, which is a matter of importance, it will be necessary to know the Rh groups of a larger series of mental defectives and their mothers than has been examined in the pioneer work of Yannet and Lieberman, and of Snyder, Schonfeld, and Offerman.

Lest any such project should break down through lack of facilities for Rh grouping we would be pleased to offer the services of our unit for this part of the work.—We are, etc.,

R. R. Race.
A. E. Mourant.

Prognosis of Coal-miners

Sir,—At a recent meeting of the Pathological Society of Great Britain and Ireland a statement was made to the effect that a belief has arisen in certain quarters in the coal field that "coal" dust is harmless when breathed into the lungs. The implication is that, unless there is at the same time exposure to rock dust, men working in a coal-dusty atmosphere run no special danger; there is therefore no need to control the concentration of dust in the air of coal-mines, etc. As the alleged basis for this belief is in the findings of the Medical Research Council's Committee on Industrial Pulmonary Disease, and as we have been associated with the investigation of pneumoconiosis in South Wales sponsored by this committee, we should like to clarify certain points.

In the M.R.C.'s First Report on Chronic Pulmonary Disease in South Wales Coalminers (Spec. Rep. Ser. No. 243, 1942) the view is put forward that "coal" (i.e., the organic, carbonaceous, combustible matter as distinct from its contained mineral matter or ash) is probably not the constituent of the dust breathed by the miners which is responsible for their pneumoconiosis. Evidence was presented to show that the siliceous matter which always accompanies the coal in the air-borne dusts and in the lungs of deceased miners is more likely to prove to be the pathogenic material. High concentrations of siliceous dust were demonstrated in all the coal-containing lesions of the lungs studied; and it was pointed out that their presence is often missed because of the masking effect of the coal, which imparts a dense black quality to the gross and microscopical appearance of the lungs.

In the latest report of this investigation (No. 3, Experimental Studies, in the press) further evidence is brought to indicate that the coal substance itself plays only a minor part in the production of the pulmonary abnormalities which have formed the basis of the pathological study. Chemical and mineralogical determinations have revealed abnormal concentrations of siliceous dust in all lungs studied, and statistical treatment of the results appears to indicate a positive correlation of severity of disease with siliceous content rather than with coal. And of the siliceous components of the dust, quartz and mica seem to be incriminated rather than kaolin, with the balance of evidence in favour of quartz as the most active pathogen. Animal experiments with purified coal (i.e., coal whose ash had been reduced to a minimum—considerably less than 1%) resulted in minimal reactions to the dust in the lungs; whereas air-borne dusts from coal-mines produced variable reactions, approximating in some cases to those obtained with highly siliceous powdered strata and dusts. These positive responses are attributed to the siliceous matter contained in the coal dust and not to the coal substance itself.

These facts lead us to reaffirm the belief that it is the siliceous matter in the inhaled coal dust which is primarily responsible for the pulmonary abnormalities to be found among workers in the coal industry. Nevertheless, many facts of this complex aetiology remain obscure. Thus, while quartz is probably the most noxious constituent, the other silicates may prove to be important; physico-chemical interaction between the combustible coal and its associated silicates may give adjuvant or inhibitory effects, differing with the class of coal; the very mixed character of the mineral fraction of the inhaled dust, including aluminous and other possibly antidotal substances, may mean that the pathogenic action of the dust is the resultant of the effects of a number of its constituents; and the knowledge of the part played by infection in pneumoconiosis is far from complete. Much further research will be required to elucidate these matters, and it is hoped that information will come from medical and scientific workers in South Wales and elsewhere, as well as from the M.R.C.'s Pneumokoniosis Research Unit, in process of formation in Cardiff.

The practical outcome of even our limited present knowledge is that the control of the more dangerous components of inhalable dust in coal-mines must depend upon control of the whole of the dust. We can say with assurance that, while sandstone-rich strata are the most potent sources of dangerous dust, harmful siliceous matter is also intimately associated with the coal seams themselves as they are worked, and indeed is contained within the interstices of the coal itself.

It is regrettable if statements in the M.R.C. Reports as to the apparent non-pathogenicity of the pure coal substance are being interpreted as meaning that "coal dust" is not dangerous to breathe. The reverse is certainly the case, and for this reason it is necessary to regard all dust generated within the coal industry as a potential hazard, and all available means should be employed to control and suppress its concentration in the air inhaled by the workers.—We are, etc.,

Pneumoconiosis of Graphite Workers

SIR,—Perhaps you will permit me to comment on the annotation (June 30, p. 916) on a paper of mine dealing with pulmonary disease in graphite workers.

1. The absence of clinical symptoms in the graphite workers concerned suggests, according to the annotation, that the lesions inferred from the skiagrams may be accumulations of graphite similar to the nodules found in iron arc welders, which at necropsy were found to be collections of iron particles. Such a point of view is not justified for the following reasons:

(*a*) Absence of symptoms does not prove that the lesions in the lung are mere accumulations. There are cases of silicosis in which the workers feel perfectly well and fit for work. Are we therefore to conclude that in these cases we are dealing merely with "deposits" of silica?

(*b*) It is important to distinguish between the terms "nodule" and "lesion" as applied to *x*-ray findings. Nodules may be either just an accumulation of dust or the reaction of the lung tissue to the presence of the dust. Lesions, on the other hand—e.g., fibrosis, dense opacities, patchy infiltrations, etc., such as are to be seen in the films of my cases—always imply a tissue reaction—that is, a pathological process. The fact that in one occupational group the nodules have been found at post-mortem examination to be mere accumulations of the inhaled dust does not allow of the conclusion that the nodules found in a different group are also accumulations. Moreover, it is not permissible to compare "nodules" with "lesions" in trying to ascertain the nature of the lesions. If it is impossible to draw conclusions from one type of nodule to another, it is even more impossible to do so from a "nodule" to a "lesion." Nothing but facts—that is, post-mortem findings on lungs, together with chemical analyses—can enlighten our knowledge of the nature of the radiological findings, to show whether they are merely deposits of, or reaction of the lung to, the dust.

2. The *x*-ray photographs of my cases unequivocally show pulmonary reactions (*vide* above). They are therefore cases of pneumoconiosis and not "suspected" pneumoconiosis, as they were labelled in the annotation.

3. Although the workmen concerned stated that they had been dealing exclusively with pure graphite and had not had any other dusty job previously, I emphasized in my paper that these statements might be perhaps incorrect. Your annotation regards the occupational histories given in my paper as insufficient. You may rest assured that the men were closely questioned as to any other possible chance for inhalation of dust. How could a negative history be given in detail?—I am, etc.,

Kingston-upon-Hull Tuberculosis Dispensary. LASAR DUNNER.

Excision of Patella

SIR,—In reviewing the subject of excision of the patella (July 14, p. 62) Mr. Fairbank acknowledges that "an excellent result may follow a properly conducted operation" and that the operation "is a sound procedure in badly comminuted fractures," but nevertheless he leaves a general impression that the results are "anything but perfect," that there is often "stumbling on rough ground," "insecurity on stairs," "gross chronic swelling and thickening, marked limitation of both flexion and extension, and varying degrees of insecurity or unreliability," with gross arthritic changes which "are not only probable but inevitable." In short he concludes that the average result varies from "disastrous" to "less disastrous."

My own impressions were completely at variance with these conclusions, but in order to be certain that I was relying on facts and not impressions, I have this week reviewed 29 patients whose patella I excised *more than five years ago.* In the course of a short letter it is not possible to analyse the difficult cases of patello-femoral ankylosis, infected fracture of the patella, patello-femoral arthritis and osteochondritis, fracture of the patella with fracture of the femoral condyle, and fracture of the patella with fracture of the shaft of the same femur, in which the range of movement after excision of the bone varied from 60° to 110° and there was residual disability due to the associated injury. But of the cases in which the patella was excised for uncomplicated, linear, or comminuted fracture there was not one single patient with chronic swelling or thickening. Not one patient had any limitation of active extension; not one had less than 140° of flexion, and most of them could touch the buttock with the heel. Not one patient complained of insecurity or instability; not one had the slightest difficulty in standing on one leg and slowly flexing and extending the knee, nor, while thus engaged, in maintaining balance when I suddenly and unexpectedly applied a powerful thrust behind the joint. Not one single patient showed "gross arthritic change"; not one who had arthritis at the time of operation showed any aggravation of it; not even patients whose patella was excised eight years ago showed radiographic evidence of disturbance in the articular cartilage of the femoral condyles which could be attributed to the operation. No matter what experimental evidence has been secured in rabbits by Timbrell Fisher and by Bruce and Walmesly there appears to be no confirmation of it in human beings.

None of these patients regarded themselves as being incapacitated in any way. On the contrary their observations varied from: "It is marvellous," "my knee is as good as ever," "I can do everything," and "it looks the same and feels the same"; to even more encouraging comments such as: "I wish the other knee was as good" (the other knee never having been injured) and "For anyone to say this is a bad operation is most unfair." One old gentleman, whose previously sutured patella had given much trouble and who subsequently refractured it, has, after excision of the bone and repair of the quadriceps tendon, been engaged for the last five years as a railwayman, jumping in and out of moving goods trains in the shunting yard. A younger man said that he had some difficulty in carrying weights up and down stairs; but I found that what he meant was that whereas he could carry 288-lb. hinds of beef on the flat he regarded 200 lb. (14 stones) as the limit of weight he could carry up and down stairs.

It is to be noted that in many cases where the five-year result is quite perfect, an extensor lag was noted three or four months after operation, and loss of the terminal degrees of active extension was sometimes evident at the follow-up review twelve months after operation. At this stage there may well be some insecurity and instability, but if the operation has been done properly it disappears; the final result is not to be judged until a year or two has elapsed. It is, however, of great importance to emphasize Mr. Fairbank's warning that it is not enough to remove the bone subperiosteally and allow the gap to remain, and I much regret that on one page of a textbook I have unintentionally quoted the work of Ralph Brooke and Hey Groves in such a way as to permit this interpretation. The gap must be closed; it must be closed by tightly "bunching up" the quadriceps tendon, lateral expansions, and ligamentum patellae; no matter how firmly the gap is closed there will be no difficulty in regaining full flexion movement if active exercises are started within three or four weeks of operation. The test of a successful result is that in the extended position the knee-joint looks quite normal, and that even in the flexed position there is no more than slight flattening of contour. Any knee which, in the words of Mr. A. G. Timbrell Fisher (July 28, p. 133), "looks like nothing on earth" has been the victim of a bad operation, or of bad after-treatment by which the sutures have torn out, and the result will, of course, be unsatisfactory. The essential feature of the operation is not simply to remove the patella, but to replace it by a firm, strong mass of fibrous tissue.

Finally I would disclaim the recommendation which I am told by Surgeon Rear-Admiral Willan has been attributed to me—namely, that excision should be the routine treatment for every fracture of the patella. In the textbook to which I have referred I do write: "If we also believe that the knee-joint suffers no loss through excision of the patella, the operation is indicated as the routine treatment for all fractures" (thus quoting the views of Brooke). But I go on to say: "If, on the other hand, we believe that the patella is necessary for protection . . . suture of the bone should be performed for fractures in young adults, and excision reserved for fractures in middle-aged and elderly patients and for severely comminuted fractures in patients of all ages." This is the view which I hoped the reader would accept, and it is the view which I still hold.—I am, etc.,

London, W.1. REGINALD WATSON-JONES.

Sweating Sickness and Picardy Sweat

SIR,—Your reply (June 2, p. 792) to the request for information regarding the sweating sickness has already been criticized by Sir Henry Tidy (July 14, p. 63), and although I do not feel qualified to discuss whether the sweats were identical with influenza, I feel that there are a number of interesting points about the strange disease which invaded this country in 1485, 1507, 1517, 1527, and lastly in 1551 which might be of interest to the inquirer.

It has been stated that Henry VII's army suffered from the "sweats," but Creighton cannot find any definite statement that this disease occurred in Henry's army of French mercenaries and Welsh adherents. There is evidence that the disease started in London. Forestier—according to Creighton—states that "the Sweat first unfurled its banners in England on 19th September, 1485," which is about three weeks after Henry's entrance to London following his success at Bosworth. Other dates of its first appearance are quoted by Creighton, but they are all later than the date quoted by Forestier. There is ample evidence that the disease took a particularly heavy toll of the well-to-do, the first outbreak in London killing two Lord Mayors and four aldermen in a week (*The Parish Register,* Charles Cox). Forestier comments upon the suddenness with which the disease attacked and killed in this first epidemic. Most observers agree that the disease attacked with great suddenness and that death could occur within six hours, although the fatality of the later outbreaks varied enormously. Creighton is convinced that the poor suffer less than the rich, and this peculiarity of the disease not only was found in England but is noted in Lübeck and Bremen. The first three outbreaks appear to have been localized in England, except for the possible occurrence of the disease in Calais and Germany in 1517. The outbreak of 1528 spread over the Continent, apparently attacked Germany, the Netherlands, Denmark, Sweden, Livonia, Lithuania, Russia, and Poland, but France seemed to have escaped. The outbreak of 1551 is interesting in that it is the only one of the five outbreaks to occur after Thomas Cromwell decided in 1538 that parish registers were to be kept. There is an entry in the register of Loughborough, Leicester, in the year 1551 as follows: "The swat called New Acquaintance, alias Stoupe ! Knave and know thy Master, began 24th June." This outbreak appears to have commenced in Shrewsbury and was confined to England.

Hirsh (*Handbook of Geographical and Historical Pathology*) discusses the further outbreaks of this disease and considers that it is the same disease as the Picardy sweat. Although no further epidemics of the "sweat" occurred in England, he has compiled a list of the outbreaks of Picardy sweat in France from 1718 to 1874, in which period there were 194 epidemics. Many of these were small and confined to single villages or communities. A review of these outbreaks, which are listed in detail by Hirsh, shows that they were almost confined to the north-west area of France, especially in the Seine-et-Oise, Bas Rhin, and Oise districts. The Picardy sweat seems to have been a disease of short duration and the epidemics were short-lived, but a large number of people were involved. The rate of sickness was 25 to 30% of the population, but there were great variations in the death rates. There is a great similarity between the two diseases—the English and the Picardy sweats. There are two interesting facts about the disease: it appeared in England on five occasions and then disappeared.

Another interesting fact is that although in 1528 the disease spread all over Europe it did not attack France, and that the French soldiery of Henry VII were immune but carried the disease into this country is an obvious suggestion.—I am, etc.,

Swindon. LLYWELYN ROBERTS.

Women in Labour

SIR,—The April 7, May 12, May 26, and June 9 issues of the *Journal* have carried reports in your correspondence section concerning the management and control of pain of women in labour. Since our own work has been discussed in all this correspondence I feel obligated to clarify, for the British medical profession, certain misunderstandings.

Caudal analgesia was originated simultaneously and independently by two French urologists—M. A. Sicard and M. F. Cathelin of Paris. It was first used in obstetrics in 1901. It was first used in obstetrics for relief of pain in terminal labour by von Stoeckel of Germany. By 1920, 4,000 cases of caudal analgesia in surgery and obstetrics had been reported.

Investigators throughout the world have modified and extended this method of analgesia into other fields. Invariably it has been abandoned from time to time for the following reasons: (1) Anatomic variations in the region of the sacrum. (2) Technical difficulties concerned with the administration of anaesthetic solutions into this area. (3) The prolonged induction time of 20 to 30 minutes necessary to provide total sensory nerve block. (4) Systemic complications which have resulted from misapplication of the technique through occult subarachnoid injection, intravascular injection either through vein, capillary plexus, or direct bone-marrow injection into the cancellous corpora of the sacrum. (5) Lack of knowledge concerning the anatomy and volumetrics of the peridural space which produces a wide range of dosage in even average cases. We are aware of all these problems. We have altered the technique in such a manner that continuous caudal analgesia, through controlled, intermittent injection, provides the patient with greater safety and permits the operator to eliminate technical difficulties and to make adjustment for anatomic variations. There can be no question concerning the fact that properly managed continuous caudal analgesia provides the parturient with greater pain relief during both labour and delivery than has been achieved by any other method. This fact has been substantiated by the observations in more than 100 American clinics, who have contributed 166 scientific papers to the medical literature.

In our own clinic at the Philadelphia Lying-In Hospital we have managed more than 3,000 labours and deliveries with this technique in the past two and a half years; Major James M. Siever, at Fort Sam Houston, Texas, in the United States Army Brooke General Hospital, has managed more than 2,800 such cases; Dr. Francis R. Irving, professor of clinical obstetrics at Syracuse University, Syracuse, New York, has managed 2,000 cases; Dr. Roy E. Nicodemus, of the Geisinger Memorial Hospital, Danville, Pennsylvania, more than 1,000 cases; Major Franklin D. Sinclair, in the United States Army Kennedy General Hospital, Memphis, Tennessee, 850; Dr. William Levine, Beth-El Hospital, Brooklyn, New York, more than 1,000; Dr. W. Royce Hodges of Cumberland, Maryland, 756; Dr. Waldo B. Edwards, United States Marine Hospital, Staten Island, New York, 700; Dr. Norman H. Miller, of the University Hospital, Ann Arbor, Michigan, 450; Dr. Julian Mines, more than 1,000; Dr. R. W. Alles, Detroit, Michigan, 400; Drs. Ellis and Sheffery, of Washington, D.C., 500. The group at Stanford University in San Francisco, California, have managed more than 1,000 cases.

From the combined reports in the American literature we find that more than 100,000 women in North America and an impressive number in South America and Central America have been managed by this technique, which is not too difficult for the average physician to master. All the reports from these clinics indicate a reduced maternal and foetal mortality and morbidity, more complete relief of pain, and a uniformly decreased third-stage blood loss compared with those seen in any general anaesthetic management.

Prof. F. J. Browne, who presented (May 26, p. 746) the dangers of caudal analgesia, quoted clinics who had, at the time of their reports, very little experience with the technique. He called attention to the delivery of the abnormal foetus in an Indianapolis clinic. He inferred that caudal analgesia was the cause of this central nervous system abnormality. He did not report that the baby was delivered twenty-four hours after caudal analgesia was abandoned under open-drop ether anaesthesia. He did not review the reports of physicians who had had success with this method because they had made an effort to master the difficulties listed above.

I should like to endorse the rational assessment of caudal analgesia presented by Mr. J. H. Peel and Dr. A. H. Galley (June 9, p. 821). Grantly Dick Read of England in his book *Revelation of Childbirth* has stated:

> "The great intensifier of stimulus interpretation is fear. This emotion, like pain, is protective and produces through the sympathetic nervous system a state of tension within the body. Thus we have the three great evils: Pain, Fear, and Tension. It is this syndrome which is responsible for the pain of labour. My contention is that the pain of labour is the result of an assault upon a primitive function which is intended to be painless. The attack is made by forces against which no protective apparatus has been developed, because the forces have not been understood and, which is probably more important, the method by which the attack is made has not been recognized. If there is any truth in this theory, it should be possible to demonstrate in practice how and where this vicious circle may be broken through. Modern science has laid the smokescreen of anaesthesia in order to hide its own lack of perception. It appears, however, that a more rational method of approach to this problem would be to discover the most vulnerable point at which to make a counter-attack, not only to resist this dangerous invader which we call fear, but also to set up an efficient protective mechanism so that the primitive function of painless childbirth may be recognized by civilized women for all time as both natural and normal. . . .
>
> The perfect painless labour will be attained, but not by the administration of drugs and agents to destroy consciousness. By careful and patient investigation of the phenomena of labour, observations will be made from different aspects. Chemical, neurological, psychological, mechanical, electrical, and even metaphysical facets to this physiological gem will flash some new message to those who care to look, and in time these varied observations will be correlated and sifted until the truth of natural painless labour is obvious to all."

Those of us who are seeking to provide more comfortable labours for all women believe that continuous caudal analgesia is a natural step along the road toward the conquest of pain. It is being made more safe; it has been used in sufficient cases for an early evaluation. We respectfully request that English physicians join us in this evaluation by verifying the reports of the experienced observers with this method.—I am, etc.,

ROBERT A. HINGSON,
Surgeon, U.S. Public Health Service.
Philadelphia.

Hydatid Disease of the Lung

SIR,—In the *Journal* of July 28 (p. 135) you published a letter from Dr. J. G. Edwards upon the subject of hydatid disease. Dr. Edwards commented upon an annotation which appeared under the heading of "Cave Canem," which annotation dealt with a review of a paper by us upon the subject of hydatid disease of the lung. In his letter Dr. Edwards attributes to us certain statements, some of which were never made in the original article, although they may have been suggested by the annotation. We would ask your permission to comment briefly on these points.

1. "Erosion of the ribs does not occur." We have post-mortem evidence that erosion of the vertebral column can occur, and we assume that the ribs may be similarly affected. The pathology is presumably comparable to erosion which occurs as a result of an aneurysm. We agree that, in general, large pulmonary hydatids cause bulging of the chest wall, and that actual erosion of bone is late.

2. "Multiple pulmonary hydatids are rare." We do not doubt that this is true in Australia if Dr. Edwards says so, but it is not true in the series of cases which have come to our notice in England. This point may be verified by referring to our case histories. We would add that at the moment there are three cases of pulmonary hydatid disease in Sully Hospital, and all have multiple cysts in the lungs.

3. "The outline of hydatid is always sharply cut unless there has been a leakage or unless there is an associated pneumonitis or pleurisy." We were at pains to make the same point in our article, and added that pneumonitis, pulmonary suppuration, emphysema, etc., often confused the diagnosis.

4. "The crescent of air is only seen in leaking hydatid." We made no statement which could be regarded as being at variance with Dr. Edwards's view.—We are, etc.,

N. R. BARRETT.
DILLWYN THOMAS.
The King Edward VII Welsh National Memorial Association, Sully Hospital, Glam.

Drilling the Glenoid

SIR,—I am glad that Surg. Cmdr. P. B. Moroney (July 28, p. 122) has found the solution of the only difficult part of the operation for recurrent dislocation of the shoulder. I have been using the dental drill with a right-angled hand-piece for the last six years, my only regret being that I did not discover it until just after my paper (*Brit. J. Surg.*, 1938, **26**, 23) was published. I obtained the hand-piece, the flexible drive, and the short twist drills from the Amalgamated Dental Co. Ltd. Messrs. Down Bros. made a fitting to attach the flexible drive to my Albee motor. They also made a little wire cage with which to hang the motor from an irrigator stand.

It is nearly always possible to pass the silkworm-gut directly through one of the holes towards the joint. Sometimes it is possible to pass it directly back through the other hole, but this is more difficult. To meet this difficulty I broke off an inch of the eye end of an ordinary straight needle, and holding this in long Spencer Wells forceps I passed it through the second hole, threaded the silkworm-gut into it, and withdrew it through the hole. Finding this quite a useful tip, I got Messrs. Down Bros. to mount the eye end of a needle at right-angles on a long handle. It is set so that when the eye faces the surgeon the handle is deflected 45° to the right and is out of the way.

Another most useful, if not essential, instrument is Ollerenshaw's modification of Murphy's hip "skid," which has been further modified for me in that it is thinner and much lighter in construction, the groove is shallower so as to fit the contour of the head of the humerus, and the handle is sharply bent back at an angle of 45° so as to get the assistant's hand out of the way. This is passed right through to the back of the joint, and it is used as a lever to hold the head of the humerus away from the glenoid cavity, thus giving a clear view of the anterior margin and room to work upon it.

I notice from Surg. Cmdr. Moroney's diagram that he passes the drill from within the joint outwards. But I have never been able to do this, because I have not liked to drag the head of the humerus so far away from the glenoid cavity. My shortest twist drills project just over half an inch from the head of the hand-piece, which itself is exactly half an inch deep, so that a working space of over an inch must be obtained before the drill can be used in this way. Incidentally, if it is safe to retract the head to that extent it should be quite easy to pass the silkworm-gut directly back through the second hole without the use of any special gadget.—I am, etc.,

London, W.1. A. S. BLUNDELL BANKART.

Day Nurseries

SIR,—It is surprising and disappointing to read such a letter as that of Dr. F. Gray (July 28, p. 135) on the above subject. If Dr. Gray had been at the Conference on Maternity and Child Welfare he would have found that the critical observations of the Archbishop, some of which were published, were shown by other speakers of his own faith to be based on a misunderstanding of the real function of nurseries and of the motives of those who advocate and support them.

It is common ground that no mothers of young children should be compelled for economic reasons to go out to work to maintain them, and no one advocates day nurseries as a means of encouraging this practice. We have not yet, however, attained such a realization of community responsibility as to make it unnecessary for any mother to go out to work. Widows with children, wives with invalid husbands, and mothers of illegitimate children may have to go out to work, and day nurseries make it possible for them to give something of the mother's love and protection which Dr. Gray rightly deems necessary for the child. Without the day nurseries, many of these children would have to go to institutions.

If the father described by Dr. Gray is unable fully to provide for his family, the denial of a day nursery to enable his wife to supplement his earnings is not likely to help the home atmosphere. And bad employers who pay low wages require rather more comprehensive treatment than the closing of all the day nurseries in the neighbourhood of their works, just as the poor harassed mother "doing two jobs" requires for her emancipation a greater realization by Parliament and people of the supreme importance of motherhood.

Supposing, however, that by an adequate endowment of motherhood, and adequate scales of sickness benefit for ailing or disabled husbands, no mother was compelled for economic reasons to go out to work, and that, indeed, no mother did so. What then? Would day and residential nurseries be unnecessary? Not so. While housing and domestic conditions are as they are, day nurseries should be regarded as an extension of the home and its amenities and not as a substitute for them. It is an extraordinary evidence of human inconsistency that many of the loud protestations of those who would have the mother shut in with her children for 24 hours a day come from individuals who have themselves been brought up by "nannies" and domestics and feel none the worse for it.

High ecclesiastics and other patriotic citizens who desire a high birth rate and happy home life must be made to realize that these cannot be attained in the modern world by the continuance of the domestic servitude which motherhood has hitherto involved in millions of working-class homes. Women are beginning to see that this servitude is not necessary, that it prevents the mother being the effective inspiration and leader of the household, and that her children respect her more naturally if her status is high and her leisure and privacy of life safeguarded.

While, therefore, conditions and domestic help are what they are and as they are likely to be for a good many years, day nurseries take the place of the nursery, which should be in every home, but is not. It is all wrong, as medical officers of health have testified, to say that it is the careless and improvident who use the nurseries most. On the contrary, it is the careful mother with a high sense of responsibility who refuses to take her own leisure unless assured that her children are safe and in skilled hands. The others do not mind leaving their children unattended or at the mercy of neighbours.

Those keen on maintaining the tone and spirit of home life should meditate on the fact that often the first break in married happiness comes with the first child. Always going out together, hitherto, only one can now get out at a time, common interests are diminished, and a drift often sets in. Day nurseries can help to keep this link of common interests and of delight in each other's society. The value of the residential nursery, too, in the case of illness or the coming of another baby needs no emphasis. Training in motherhood, also, is recognized as desirable for senior adolescent girls; day nurseries have a great part to play in this.

Home helps and a mobile nursery staff or "nannie" service (as tried out by the County Public Health Department of Lanark) may help to solve this problem in days to come. In the meantime, I hope Dr. Gray will agree that we must keep an adequate number of day nurseries.—I am, etc.,

T. DRUMMOND SHIELS.

SIR,—It is unfortunate that Dr. F. Gray (July 28, p. 135) relied upon half-truths to support his adverse criticisms. Of a peacetime day nursery (described by him as "a blot on our civilization") I submit the following is a much more accurate picture:

1. *The Father.*—He might be disabled through illness from earning a living, or because of an industrial slump be out of work or "on short time." He might have deserted his wife or be serving a prison sentence. He might own a one-man business and have to depend on his wife's help in it. In none of the above circumstances could he justly complain to be "generally forgotten or ignored."

2. *The Mother.*—Her "home," because of her straitened circumstances, would more often than not consist of lodgings, one room, so that her "household duties" would be the least exacting part of her daily toil.

3. *The Child.*—I wonder if your correspondent has seen the normal happy children who are regular attendants in a well-run nursery. They must be exceedingly clever actors if they cherish feelings such as he describes. Has he ever witnessed the reunion of the mother and child when she fetches it after work, the little one eager to tell her of the day's happenings and she so glad to listen? Nothing "cross and irritable" about her, but a display of love all the more affectionate and ardent because of the temporary separation.

Far from being a blot on our civilization, the day nursery takes its place with the school and the hospital in the service it can provide for the parent and the child when the mother is unfortunately faced with the economic necessity to go out to work.—I am, etc.,

London, N.W.11. L. STUART WOOLF.

Sensitivity to Lanette Wax

SIR,—Certain cases of sycosis and other infective dermatoses are found to become worse after the application of penicillin cream, in spite of the fact that they have previously been proved bacteriologically to be due to organisms sensitive to penicillin. Positive results have been obtained by us in such cases from patch-testing with lanette wax, and the lesion may then respond to penicillin in saline. It would appear, therefore, that the lanette wax base is the cause of the aggravation of these cases, and that the widespread use of lanette wax as a base is not without its dangers, especially on skins sensitized from the use of a succession of irritating agents.

In this connexion, the large-scale production for sale of a lanette wax base appears open to criticism, and, although it may be necessary as an immediate measure to help the practitioner when penicillin comes on the open market, the supply departments of the manufacturing chemists should spare no efforts to ensure the future production of a more stable and less irritating base.—We are, etc.,

ARTHUR BURROWS.
London Hospital, E.1. B. RUSSELL.

Sensitization to Synthetic Resins

SIR,—In their article on sensitization to nickel spectacle frames Taylor and Fergusson (July 14, p. 40) refer to the notes of Thistlethwaite (1943) and Gray (1943) on sensitization to artificial-shell spectacle frames, and describe the lesion in both as being related to dye. Thistlethwaite, in fact, does not mention dye as an aetiological agent, while Gray, although stating that the patient was sensitive to brown and black dyes, does not say whether the peccant frame was dyed or clear. Since Berkoff (1938) seems to have shown that the plasticizer (tricresyl phosphate) used in some synthetic resins may act as an allergen, it would be unfortunate if the view were now accepted that the clear type of artificial resin was necessarily safer than the dyed.

It will be interesting to hear if cases of sensitization occur among the troops now anointing themselves with the other well-known plasticizers—dibutyl and dimethyl phthalate—recently discovered to be insect repellents.—I am, etc.,

The University, Glasgow. A. C. Lendrum.

Penicillin Injection Apparatus

Sir,—The apparatus described by Mr. Ronald Edwards (July 21, p. 86) for injecting penicillin appears to be unnecessarily complicated. I feel that the following is simpler and can be set up in a few minutes from materials available at most hospitals.

A standard intravenous drip set is used. The glass drip connexion is removed, and a two-way tap, such as is used for chest aspiration, substituted. Attached to this is a syringe of suitable size according to the volume of penicillin solution to be given. The syringe may be fixed to the drip stand. A sterile rubber-glove finger should be placed over the handle of the piston of the syringe and over the end of its barrel to keep the inside of the syringe sterile while it is exposed to the air when the piston is fully depressed. The whole apparatus is filled with penicillin to drive out the air before the needle is inserted into the muscle. The needle should be firmly strapped in place.

To give an injection the two-way tap is turned so that the penicillin is drawn from the reservoir into the syringe. The handle is then turned so that the contents of the syringe can be injected down the distal tubing into the patient. It is advisable with the present-day rather poor rubber tubing to tie the tubing to the metal with thread to withstand the pressure of the injection. An old two-way tap may leak, but a little vaseline applied to the outside will prevent this.—I am, etc.,

Swallowfield, Nr. Reading. F. R. M. Elgood.

Cinematograph Films of Aviation Physiology

Sir,—We note in the *Journal* of July 21 (p. 75) the paper by Dr. B. H. C. Matthews based on the first of his Oliver-Sharpey lectures. You may like to draw the attention of your readers to the following films which exist on aviation physiology:

	Running Time
(1) Use of Oxygen in High Altitude Flying	22 min.
(2) Effect of Centrifugal Force in Air Crews	19 „

They are held by the Air Ministry (Dept. T. Films), Alexandra House, Kingsway, London, W.C.2, who are prepared to lend them for showing to selected audiences if early application is made for them. The films are available in 35 and 16 mm. and are talkies. As they are designed for teaching air crews the approach is elementary, but nevertheless interesting to the ordinary practitioner who has no special knowledge of the subject.—I am, etc.,

Ronald MacKeith,
Chairman, Medical Committee,
Scientific Film Association.

Recommendations of the Goodenough Report

Sir,—Medical graduates of the Universities of Oxford, Cambridge, and London have a very particular interest in certain recommendations of the Goodenough Report on Medical Schools (Stationery Office, May, 1944). These universities have been singled out for criticism by the Goodenough Committee, appointed in March, 1942, by the then Minister of Health. London University is the most vitally concerned as the university training approximately one-half of the medical students south of the Tweed and furnishing thirteen out of the twenty-one teaching hospitals in England and Wales.

The system of Final Examinations adopted in Oxford, Cambridge, and London is specifically attacked. It is contended that "any student who has followed his course of study to the satisfaction of his teachers should be able to obtain a degree mainly for the work he has done during his course, checked by a reasonable examination." This "reform" (?) is called "internalization" by the committee. London receives the brunt of hostile criticism in the following statement:

> "Instead of recognizing that every student, who has successfully negotiated the earlier examination fences and has carried out a satisfactory clinical course, could reasonably be given his degree with the minimum of examination, the University still insists on setting him a stiff 'external' examination reminiscent of the days when the University was only an examining body and when its chief claim to fame was in the severity of its examinations" (p. 209).

It may be pertinent here to remark that of the ten members of the Goodenough Committee only one is a graduate of London University, and he had taken a leading part seven years ago in an agitation to bring about some measure of amalgamation of the final qualifying examinations of the English Conjoint Board with the London M.B., B.S. degree—an agitation defeated with complete finality in 1938. This "internalization" would be wholly impossible for Oxford and Cambridge to effect since their final examinations are based upon training given in London medical schools and in this sense are consequently exclusively external.

Another surprising recommendation made by the committee is set out as follows:

> "A drastic overhaul of the medical curriculum is an urgent necessity, and its accomplishment might be made a condition to be satisfied before any increase is made in Exchequer grant in aid of undergraduate medical education. It is recommended that the General Medical Council should take the initiative in this matter without delay" (p. 31).

These two proposals call for comment.

1. The attempt to attach to Exchequer grants conditions as to the content and duration of the medical curriculum (for the "overhaul" involved reduction of training from 7 years to 4½) is a new and sinister feature. In the House of Commons on January 18 the Minister of Health announced the "decision" of the Government to accept this financial enforcement of educational policy upon the universities, notwithstanding that the recommendation had no authority other than that of an "interdepartmental committee" whose proposals had not been submitted to Parliament.

2. The selection of the General Medical Council as the body which should "take the initiative" in moulding the medical curriculum of the universities betrays a singular ignorance on the part of the committee, both of the functions and of the traditions of the G.M.C. The G.M.C. is not concerned, and has never been concerned, with teaching; that it should be regarded as the proper arbiter of the teaching of medicine in all our universities seems to me fantastic. I have been favoured with a copy of the Memorandum of Evidence given to the committee by the G.M.C., and one's impression of that evidence is that that body shows a commendable prudence in its reception of the proposal. In a correspondence which lies before me with one of the most famous Presidents of the G.M.C. in our generation, the late Sir Norman Walker, he lays down the policy regarding the medical curriculum which he said the G.M.C. had pursued for eighty years and had no wish to alter. This policy is set out in detail in the Memorandum of Evidence. The Council is content to leave to the teaching institutions the initiative in determining curricula, reserving to the Council the duty laid upon it by statute—namely, "to maintain a standard of efficiency at qualifying examinations sufficient to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, of surgery, and of midwifery."—I am, etc.,

The Athenaeum, S.W.1. E. Graham-Little.

The Germans were responsible for a complete breakdown in the programme of malaria control in Italy; the results were particularly serious in the province of Latina, which includes the Pontine Marshes. Plans are now being prepared by U.N.R.R.A. for the allocation of D.D.T. sufficient to spray 1,200 houses in the mined and flooded areas of the province. U.N.R.R.A. staff, under Lieut.-Col. V. B. Lamoureux, engineering consultant to the Epidemic Control, are in constant touch with operations, and three young Italian engineers are being trained to supervise the work of malaria control units anywhere in Italy. Vehicles, bicycles, and funds to provide labour and to meet the increased cost of living have also been provided.

Obituary

W. ALDREN TURNER, C.B., M.D., F.R.C.P.

Dr. William Aldren Turner, consulting physician and senior neurologist to King's College Hospital, and the National Hospital, Queen Square, died at the age of 81 on July 29. Born in 1864, he was the eldest son of the late Sir William Turner, K.C.B., F.R.S., Principal of the University of Edinburgh from 1903–16, and was educated at Fettes and Edinburgh University. After qualifying M.B., C.M. in 1887 he became house-physician at the Edinburgh Royal Infirmary. He took the Edinburgh M.D. with gold medal in 1892, and the M.R.C.P.Lond. in 1899; he was elected a Fellow in 1896.

Aldren Turner went to King's College in 1892 as assistant to Dr. (later Sir) David Ferrier in the neuropathological laboratory. He was subsequently appointed demonstrator and then lecturer in neuropathology. In 1899 he was appointed assistant physician to King's, and 9 years later physician in charge of neurological cases and lecturer in neurology in the medical school. Aldren Turner was on the medical staff of the West London Hospital, and from 1900–7 physician to the National Hospital, Queen Square. He delivered the Morison Lecture at the Royal College of Physicians of Edinburgh in 1910, and the Bradshaw Lecture at the Royal College of Physicians of London in 1918, when his subject was "Neuroses and Psychoses of War." When he retired from the active staff of King's in 1928 he was appointed consulting physician to the hospital and Emeritus Lecturer on Neurology in the medical school. It was mainly through his efforts that the Ferrier Prize in Neurology was established at King's in 1929.

He published a large number of papers on neurological subjects, *Epilepsy, a Clinical Study*, in 1907; and, jointly with Dr. Grainger Stewart, *Textbook of Nervous Diseases* in 1910. During the war of 1914–18 Aldren Turner made a special study of nervous and mental shock and was gazetted a temporary colonel in the Army Medical Service, for special duties in France. He was also neurologist to the Forces at home from 1915–19, and to the War Office Medical Board from 1919–40. He was at one time president of the Neurological and Psychiatric Section, Royal Society of Medicine, and was a member of the War Office Committee on Shell Shock from 1920–1. He joined the B.M.A. in 1895 and was vice-president of the Section of Psychology at the Ipswich Meeting in 1900.

SIR W. GIRLING BALL, F.R.C.S.

Surg.-Lieut. J. B. GURNEY SMITH, R.N.V.R., writes: As one of the vast number of students who trained at Bart's during the brilliant deanship of Sir Girling Ball, may I pay my brief tribute to a great man. His work for the new medical school will be his lasting memorial, and was an enterprise needing special enthusiasm and drive, which he so manifestly possessed. He was a dynamic teacher of surgery, as those who attended his lectures and ward rounds can easily testify; his lectures on "waterworks" will always live in one's memory. As dean he had the affairs of his students much at heart. I can well recall his saying on the platform in the Great Hall of Bart's on one occasion: "I will do anything for my boys and my boys will do anything for me"; which remark drew forth much acclamation. He liked to think of us as his "boys." His "John Bull" heartiness was one of his most marked characteristics. Another great Bart's figure has gone and has left behind work of imperishable glory.

The death of Dr. P. F. MCFARLAN of Stirling has brought to a close a period of over forty years' service to the community not only in Stirling but in a wider area in Stirlingshire and the neighbouring counties. A native of Dumfriesshire, Patrick Frederick McFarlan graduated M.B., Ch.B. at Edinburgh University in 1901, and after resident appointments in Edinburgh Infirmary and other hospitals he settled in general practice in Stirling, which he continued until his death. In 1905 he took his F.R.C.S.Ed., and some years later was appointed surgeon to Stirling Royal Infirmary, which was then little more than a cottage hospital. He held this appointment until 1938, and during that time steadily raised the quality of the surgery and the prestige of the hospital. He always maintained that the most comprehensive hospital service should be provided locally, and it became obvious that this was not possible in the cramped and old-fashioned building in the old town. Overcoming opposition he was the prime mover in securing a magnificent site on the outskirts of the town, and in raising funds for building the 120-bed hospital which was opened in 1928. Continuing as senior surgeon he fulfilled the duties of medical superintendent, and Stirling Infirmary became one of the leading provincial hospitals in Scotland. For his services he was awarded the O.B.E. and appointed as chairman of the hospital, an office he still held when he died. Mr. McFarlan was a confirmed believer in the co-operation of voluntary hospitals with local authorities, and he was instrumental in forming the Divisional Council for Hospital Services for Stirlingshire, Clackmannanshire, and West Perthshire. For many years he was a member of the Branch Council of the B.M.A., and was president of the Branch for two periods; he was also a co-opted member of the Hospitals Subcommittee of the Scottish Committee of the B.M.A. "Paddy" McFarlan will be remembered by his colleagues as a sound, practical surgeon and a very helpful general consultant, as an outstanding hospital administrator, and as a very lovable man. He leaves a widow and four children, of whom a son and a daughter are members of the medical profession.

We regret to announce the death on July 19 of Dr. NORMAN BLACK, O.B.E., *M.C.*, at the age of 63. He was born at Greenock in 1881, the youngest son of the late John Robert Black, M.D., and was educated at King William's College, Isle of Man, and at the University of Edinburgh, where he studied medicine from 1900 to 1905, qualifying M.B., Ch.B. After leaving the university he held medical appointments in Dublin before going to Singapore as lecturer in obstetrics at King Edward VII Medical School. He was granted a commission in the Singapore Volunteer Corps, attaining the rank of major, and was officer commanding the Singapore Volunteer Field Ambulance. Dr. Black returned home in 1914 to enter the R.A.M.C. in the war of 1914–18; he served in France and was twice wounded; he was awarded the *M.C.* In 1917 he was appointed senior medical officer to the Straits Settlements, and in the following year received the O.B.E. Ill-health obliged him to retire from Singapore in 1921 and he settled in practice at Waddesdon, Bucks, where he became medical officer and examiner to the county council. At the outbreak of war in September, 1939, Dr. Black organized a first-aid party at Waddesdon and later became medical officer to the local Home Guard unit. He retired from practice as recently as June 30 and went to live at Quainton. Dr. Black was an all-round sportsman and shone particularly at Rugby football, representing the Isle of Man when only 16 years of age; he was captain of the Singapore Scottish Rugby XV. He was a keen angler. Dr. Black had unbroken membership of the British Medical Association from 1906. His death came as a great shock to the people of the Waddesdon area, where he was held in great esteem, especially by the many old people to whom he showed much kindness, and the general feeling was clearly demonstrated by the attendance at the funeral service on July 24.

The following well-known medical men have died abroad: Dr. PIERRE ABRAMI, a leading Paris physician, aged 66; Dr. FRANCISCO MURILLO PALACIOS, the Spanish epidemiologist who was one of the founders of sanitary organization in Spain; Dr. JUAN SANCHEZ COVISA, member of the National Academy of Madrid, emeritus professor of the Madrid Faculty of Medicine and an eminent dermatologist.

The Services

Col. M. S. Joshi, I.M.S., has been appointed Honorary Surgeon to the King in succession to Major-Gen. J. S. S. Martin, C.S.I., I.M.S., retired.

Lieuts. A. O. Harries and G. Ollerenshaw, M.B.E., R.A.M.C., have been awarded the M.C., and Lieut.-Col. (Temp.) G. M. Denning, R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in North-West Europe.

CASUALTIES IN THE MEDICAL SERVICES

Died.—Lieut. John Evans, R.A.M.C.

Universities and Colleges

UNIVERSITY OF LONDON

Westminster Hospital Medical School

At the opening of the new academic session at Westminster Hospital Medical School the inaugural address will be delivered by His Grace the Archbishop of Canterbury in the Sir Edward Meyerstein Lecture Theatre on Monday, Oct. 1, at 3 p.m.

The following candidates have been approved at the examination indicated:

M.D.—*Branch I (Medicine)*: W. R. S. Doll, D. B. Jelliffe, Monica K. McAllen, G. Watkinson. *Branch II (Pathology)*: L. E. Glynn, B. Levin. *Branch V* (*Hygiene*): E. R. Bennion.

UNIVERSITY OF MANCHESTER

Sydney Thomas Crowther, M.R.C.S., L.R.C.P., has been appointed Lecturer in Bacteriology; Ralph Cocker, M.B., Ch.B., L.D.S., Lecturer in Parodontia; and Eugen Pollak, M.D., Lecturer in Neuropathology.

UNIVERSITY OF DURHAM

The Court of the University of Durham has recently approved the appointment of Lieut.-Col. Frederic Herbert Bentley, F.R.C.S., to the Chair of Surgery in the Medical School of the University.

UNIVERSITY OF WALES

The following candidates in the Welsh National School of Medicine have been approved at the examinations indicated:

M.B., B.Ch.—*Surgery*: A. H. Beynon, G. E. Davies, G. R. Davies, E. D. Edwards, P. Griffiths, J. C. Ham (with distinction), J. M. Hughes, I. D. Jacobs, S. T. James, Mary Lawrence, Bernice G. Lewis, R. Medlicott, Isobel F. A. Mitchell, Goronwy Owen, Barbara M. Parker, Enid A. Reed, Beryl P. Roberts, Jean T. Smith, D. V. Thomas, D. M. Watkins. *Medicine*: W. H. Beasley, G. K. Davies, Mair Ll. Edwards, J. H. Edworthy, Hannah P. Evans, Myrddin Evans, P. Griffiths, W. J. Jenkins, D. O. Lewis, D. R. Lewis, W. T. Lloyd, Joy A. MacGregor, Barbara D. S. Marshall, J. Matthews, D. B. Price, Olwen V. Rees, Amelia Rowles, Gwladys M. Sewart, D. Tooms, L. L. R. White, Catrin M. Williams, D. M. Williams, Roberta Williams, W. O. Williams. *Pathology and Bacteriology*: Nora C. Curran, Margaret E. Davies, Clare G. M. Dillon, O. W. James.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly Comitia of the College, held on July 26, with the President, Lord Moran, in the chair, the following were elected officers for the ensuing year: Censors, C. M. Hinds Howell, G. Graham, W. H. Wynn, D. Hunter; Treasurer, W. G. Barnard; Registrar, H. E. A. Boldero; Assistant Registrar, A. A. Moncrieff.

The Registrar announced that Hilary F. H. Hamilton had been awarded the Murchison Scholarship for 1945. The Baly Medal was awarded to Prof. S. A. S. Krogh for his outstanding contributions to the knowledge of the capillaries and of related physiological problems in cellular nutrition and respiration; the Moxon Medal to Sir Alexander Fleming, F.R.S., for his work on penicillin; and the Weber-Parkes Prize to Dr. E. L. Opie for his work on the pathogenesis of tuberculosis.

Dr. Geoffrey Bourne was elected the representative of the College on the Central Council for District Nursing in place of the late Sir Stanley Woodwark.

Sir Maurice Cassidy was appointed Harveian Orator and Brig. D. Evan Bedford Bradshaw Lecturer, both for 1946. The following lecturers for 1946 were also appointed: Goulstonian, Lieut.-Col. W. R. M. Drew; Lumleian, Dr. J. M. H. Campbell; Oliver-Sharpey, Dr. R. D. Lawrence; FitzPatrick, Sir Arthur MacNalty; Abrahams, Prof. C. A. Lovatt Evans, F.R.S.; Charles West, Prof. J. C. Spence. Brig. E. R. Boland was appointed Croonian Lecturer for 1947.

Sir Hans Sloane's Statue

Dr. J. D. Rolleston, representing the College on the Committee of Management of the Chelsea Physic Garden, stated in his annual report that in September, 1939, steps were taken to protect the marble statue by Michael Rysbrach (1733) of Sir Hans Sloane from damage by enemy action. The wooden casing surrounding the statue was renewed from time to time and lately showed signs of collapse owing to the settlement of the sand and ballast fillings. As the risk of air-raid damage was considered to be over at the end of hostilities in Europe, Sir William Collins, chairman of the Physic Garden Committee, gave authority for the statue to be uncovered and inspected. The right arm was then found lying on the ground, probably as the result of the raids, and was replaced.

The buildings chiefly damaged by enemy action were the laboratory building, including the large plant house, the greenhouse adjoining the laboratory, and the sheds on the south-east side of the Garden and the sunk pits.

The following, having satisfied the Censors' Board, were elected to the Membership of the College:

M. Anderson, M.D., Major A. W. Bagnall, M.D., R.C.A.M.C., Capt. J. R. Bolton, M.B., R.A.M.C., P. T. Bray, M.B., E. F. B. Cadman, M.B., K. D. Crow, M.B., T. B. Staveley Dick, M.B., Capt. F. L. Dyson, M.B., R.A.M.C., Surg. Lieut. I. G. Fergusson, M.B., R.N.V.R., A. C. Frazer, M.D., S. A. M. Garibian, M.B., W. S. L. Gilchrist, M.D., I. R. Gray, M.D., I. T. Twistington Higgins, L.R.C.P., L. Hornung, M.D., R. F. Jennison, M.B., D. E. R. Kelsey, M.B., A. G. Leatham, M.B., D. McCracken, M.B., F. G. W. Marson, M.B., R. B. Meyer, M.B., A. Muir, M.B., S. Pickford, M.B., P. K. Robinson, M.B., Daisy M. Smith, M.B., Squad. Ldr. W. M. L. Turner, M.B., R.A.F.V.R., D. Verel, M.B., W. D. Wylie, M.B.

Licences to practise were conferred upon 130 candidates (including 21 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws:

A. F. Alvarez, G. S. Andrew, R. C. B. Arthur, P. W. Arundell, Margaret W. Barbour, R. Bellamy, N. J. Blockey, H. Bourne, R. P. Bradshaw, J. L. Braithwaite, D. G. Breeze, R. G. Britt, Mary Brooks, R. B. Broughton, Joyce B. Burke, E. H. W. Burt, R. E. Church, C. J. M. Clark, K. S. Clarkson, W. D. Clarkson-Webb, H. F. Clay, G. Clayton, J. M. Cliff, E. Cluer, E. de M. Connell, T. M. Cullingworth, W. P. Dallas Ross, D. G. H. Davies, G. R. Davies, I. N. Davies, J. A. R. Debenham, Phyllis Denman, Margaret L. Dennis, Phyllis M. De Saram, J. McG. Dutton, A. B. Eastwood, W. T. Edwards, J. G. R. Ellis, D. P. F. Embleton, A. S. Falconer, D. L. B. Farley, Alice Faulkner, W. S. R. Fenton, J. W. Ferguson, R. H. Freeman, Viola M. Frymann, D. H. Gawith, A. Gilani, A. W. Gilks, A. M. Goldstein, R. Diplomas

Diplomas in Anaesthetics were granted, jointly with the Royal College of Surgeons of England, to the 35 candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of June 30 (p. 928), and in Laryngology and Otology and in Psychological Medicine to the candidates whose names appeared in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 28 (p. 139).

Diplomas in Public Health were granted, jointly with the Royal College of Surgeons of England, to Mary E. Budding, Joan F. Heffernan, A. C. Knight, Rosie Morris, and W. N. Taylor.

Medical News

The result of the Scottish Universities election was announced on Aug. 2 and the three representatives in the last Parliament were all re-elected. Sir John Anderson and Sir John Boyd Orr were returned at the first count and their surplus votes secured the re-election of Sir John Graham Kerr. The final figures were as follows: Sir John Anderson (Nat.), 16,011; Sir John Boyd Orr (Ind.), 10,685; Sir John Graham Kerr (C.), 8,999; Dr. Halliday G. Sutherland (Lab.), 4,075; and Col. R. S. Weir (L.), 3,319.

U.N.R.R.A. announces that Dr. Andrew Topping has been promoted to be assistant deputy director general operations, and will have, among other duties, administrative supervision of the Health and Welfare Divisions. His place as director of the Health Division is to be taken by Dr. Neville Goodman, and the senior deputy director is Lieut.-Col. Hugh R. Leavell, United States Public Health Service. Among other appointments are that of Dr. A. P. Meiklejohn as adviser in nutrition (through the courtesy of the Rockefeller Foundation); Major-Gen. Sir Ernest Cowell as principal medical officer, Greece, in place of Dr. I. Balfour Kirk, who becomes medical adviser to the U.N.R.R.A. headquarters, Germany; and Col. A. Campbell Macrae, late I.M.S., principal medical officer of the U.N.R.R.A. personnel operating in the British Zone, Austria. Sir Raphael Cilento, Director-General of Health and Medical Services, Queensland, Australia, has taken up duty as principal medical officer attached to the 21st Army Group.

Dr. M. D. C. Taylor has been appointed Governor of Holloway Prison. She is the first woman to hold the position and the youngest Governor ever appointed in the Prison Service. Dr. Taylor qualified M.R.C.S., L.R.C.P. in 1937 from the London School of Medicine for Women, and after house posts at the Royal Free and the Elizabeth Garrett Anderson Hospitals was appointed a part-time assistant medical officer at Holloway Prison in 1942, becoming a whole-time medical officer there in April, 1944.

The Volunteer Car Pool for the transport of hospital cases ceased on July 31; but a voluntary car service for sitting patients who need special transport to hospitals or clinics is being organized jointly by the St. John Ambulance Brigade, British Red Cross, and W.V.S. This will be known as the Hospital Car Service, and hospitals wishing to use it should apply to the local representative of one of these organizations.

Dr. Edith Gilchrist has been appointed to the Research Fellowship of the Association of Anaesthetists of Great Britain and Ireland, which she is holding at the Royal Free Hospital from Aug. 1.

The names of two more medical candidates at the General Election have been brought to our notice. Dr. Donald McIntosh Johnson and Lieut.-Col. Eric Townsend, *M.C.*, R.A.M.C., both Liberals, stood for Wiltshire (Chippenham) and Yorkshire, West Riding (Skipton) respectively, but were unsuccessful, a Conservative in each case being returned.

Restrictions on the conditions for which injectable extract of liver may be used are removed in a new Order—the Liver Extract (Regulation of Use) Order, 1945—just issued. The use of oral preparations of liver (including proteolysed liver and desiccated liver) is permitted on the prescription of a registered medical practitioner for the treatment only of pernicious and other megalocytic anaemias. The Order prohibits the use for oral administration of any preparation containing liver extract combined with any other active ingredient, except stomach extract.

Headquarters of Sector V of the Emergency Hospital Service moved on Aug. 1 from Stanmore to the Middlesex Hospital, London, W.1 (Tel.: Museum 7138).

The mass radiography unit from St. James's Hospital, Leeds, started a month's survey at York on July 9. The unit has been lent to various local authorities, and York is the first town after Leeds to make use of it.

The address of the central office of both the Nuffield Foundation and the Nuffield Provincial Hospitals Trust is 12–13, Mecklenburgh Square, London, W.C.1.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* notifications of infectious diseases were higher than last week by the following figures: whooping-cough 60, dysentery 43, diphtheria 22; there were 600 fewer notifications of measles, and 49 fewer of scarlet fever.

No fresh outbreaks of diphtheria of any size were reported; the increase was due to isolated cases scattered throughout the country. The region chiefly affected was Wales, where there was an increase of 14. The incidence of whooping-cough fell in most areas of the country, but there were relatively large rises in a few counties: Lancashire reported 48 more cases than last week, Cornwall 36, and Middlesex 27. Measles notifications are still on the decline, though Buckinghamshire reported 40 more cases than last week, and Sussex 24. In Middlesex notifications of dysentery rose from 13 to 45 (Heston and Isleworth M.B. 19, Tottenham M.B. 11); and in Buckinghamshire from 4 to 24 (Amersham R.D. 23). The other large returns were from London 41, Lancashire 24, Warwickshire 18, Essex 15, and Surrey 10.

In *Scotland* notifications of scarlet fever, measles, and diphtheria rose by 38, 35, and 29 respectively. There were only 44 cases of dysentery—the lowest total for the past eleven months. The increase in diphtheria was mainly in the west; in Glasgow notifications rose from 23 to 40.

In *Eire* notifications of whooping-cough fell by 31, 19 of the 20 cases being notified in Dublin C.B. The incidence of infantile diarrhoea fell by 10 but remained high, 49 cases being reported in Dublin C.B.

In *Northern Ireland* a rise of 12 in the notifications of diphtheria brought the total to the level of the previous three months. The total for scarlet fever was halved by a decrease of 18.

Week Ending July 28

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,223, whooping-cough 1,092, diphtheria 370, measles 2,581, acute pneumonia 322, cerebrospinal fever 42, dysentery 226, paratyphoid 7, typhoid 11, poliomyelitis 22.

No. 29

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vita Statistics in the British Isles during the week ended July 21

Figures of Principal Notifiable Diseases for the week and those for the corre sponding week last year, for: (a) England and Wales (London included). (b London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland. (d The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week

Stillbirths	209	12	33			212	17	35		
Rate per 1,000 total births (including stillborn)			35					35		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Paronychia of Toe

Q.—*A patient aged 72 has been plagued with recurring paronychia of the great toe. He has to go on working, but often in misery and fear of chance blows, etc. Suggestions short of surgical procedure would be welcomed.*

A.—The first thing to do is to exclude or to detect any constitutional disorder. Test the urine for sugar, make sure there is no chronic renal lesion, and examine the peripheral arteries, for there is a possibility of a deficient circulation to the toes.

If constitutional disease can be excluded, the symptoms point to a paronychia constantly recurring owing to the irritation of the edge of the nail—the rather badly termed "ingrowing toe-nail"; in such cases there is a chronic infection of the sulcus between the nail and its fleshy surroundings. Unless this infection be eradicated recurrence of the paronychia is certain. Since the questioner excludes surgical measures, one must place reliance on the application of substances which combat the infection. Great benefit may follow the local application of tincture of iodine once a day. Insufflating the part with sulphanilamide powder, or with a powder made up of a mixture of sulphonamide and penicillin, will certainly offer a good chance of cure. Fomentations should not be applied. It is relevant to add that the certain cure of the condition may be brought about by the minor operation of removal of half the nail together with the underlying nail-bed under local analgesia. This operation if done expertly causes no shock and very little discomfort.

Contraceptive Methods

Q.—*Being about to return home after six years in the Army, I would like guidance on contraceptive methods. In my previous experience a condom is unsatisfactory, and a chemical contraceptive not very safe. A "Dutch cap" must presumably be fitted by an expert. If the latter is used, should the woman douche the vagina after 8 hours before removing the cervical cap? I shall be grateful for advice.*

A.—The only safe contraceptive method consists of barrier plus chemical. No cap or chemical used by itself is safe. The combination, however, gives a very high degree of safety—probably about 98%. The woman must use the method, which must be provided by a doctor understanding contraceptive technique. Such advice can be obtained from a doctor specializing in these matters, or from a clinic. A list of all the clinics in the country can be obtained from the Family Planning Association, 69, Eccleston Square, London, S.W.1, who also are frequently able to suggest the name of a doctor known to be knowledgeable in these matters and residing in an area where there may be no clinic. As a last resort, the F.P.A. endeavours to give help by post, but this usually consists in recommending the use of a condom, together with a suitable soluble, or occasionally the use of a sponge and condom, or even sponge and chemical. These latter methods, however, all have aesthetic objections and are liable to fail. It is also difficult to assess the relative size of sponge needed by the woman. The condom does certainly interfere with the satisfactory performance of the act and is one of the causes of inability to obtain orgasm, and, indeed, in some cases prevents effective erection on the part of the man. There is no soluble pessary effective enough to be used by itself. All have a failure rate. If a woman is using a cap and a soluble, it should remain in position for 8 hours and then be removed. Douching is contraindicated.

Those medical officers consulted by men who are returning from abroad after a long absence, and who are concerned about their marriage problems, would be well advised to refer these men to the Marriage Guidance Council, 78, Duke Street, London, W.1. The Council has expert advisers who can deal practically with the various problems of marital adjustment, including, where necessary, effective contraceptive advice.

Hyperhidrosis of the Palms

Q.—*A case of severe hyperhidrosis affecting the palms of the hands has not responded to astringent lotions, x-ray treatment, and calcium injections. What more can be done?*

A.—Hyperhidrosis of palms is the result of an emotional disturbance and calls for investigation along those lines. As a palliative, puddling in a 10% solution of sodium hexametaphosphate night and morning or the free use of the following dusting powder is helpful:

Acid. salicyl. 2%.
Sod. hexametaphosphat. 5%.
Zinc. oxid. }
Talc. } āā ad 100.
Acid. bor. }
Ft. pulv.

Protection of X-ray Workers

Q.—*What are the Home Office regulations regarding the protection of x-ray workers in industry? A local firm is using an x-ray plant for inspection purposes, and I understand that periodic blood counts and examinations are required. Is a plain blood and leucocyte count sufficient, or is a differential count necessary?*

A.—There are no formal Home Office rules governing the protection of *x*-ray workers in industry. The general precautions to be adopted by all *x*-ray workers with regard both to protection of the equipment and that to be embodied in the rooms housing the equipment, also the general rules governing the safety of personnel, are covered by the recommendations of the International *X*-ray and Radium Committee, copies of which can be obtained on application to the General Secretary, British Institute of Radiology, 32, Welbeck Street, London, W.1.

On the other hand, the Chief Inspector of Factories exercises rigorous supervision over *x*-ray laboratories in industrial organizations, and his recommendation is that workers shall carry small pieces of film in the course of their work; these are to be forwarded to the National Physical Laboratory at regular intervals for assessment of the amount of radiation received by each individual worker. The films and conditions governing their use may be obtained by application to the Director, National Physical Laboratory, Teddington, Middlesex. Differential blood counts are necessary in the case of all workers in radiological industrial laboratories, and they should be carried out at least twice a year. Most industrial firms using *x*-ray methods of inspection employ a consultant to advise them with regard to suitability of equipment and general questions of protection.

(See also questions and answers in Sept. 23, 1944, p. 422, and April 1, 1944, p. 480.)

Hepatitis Mortality Rates

Q.—*What are the mortality rates of infective hepatitis and homologous serum jaundice?*

A.—Mortality rates in epidemics of infective hepatitis have ranged from 0.13 to 0.44%. In the outbreak of homologous serum hepatitis in the American Army the mortality rate was 0.24%. In some small epidemics of infective hepatitis and of homologous serum hepatitis the mortality rate has appeared to be somewhat higher. The rates given should be considered as approximations owing to the difficulties of ascertaining the true number of deaths and of cases. It should also be noted that no allowance is made for differences of age and sex distributions in the deaths or cases.

Penicillin Inhalation

Q.—*A patient aged 51 has daily attacks of asthma. He spits a large quantity of sputum. Tubercle bacilli not present, but streptococci and other cocci numerous. Culture yields Str. viridans in abundance, haemolytic streptococci, non-haemolytic streptococci, Staph. aureus, all in moderate quantity. Would penicillin be useful in this case?*

A.—There are two necessary conditions which must be fulfilled before penicillin treatment of any infection is likely to be successful. They are: (1) the organisms causing the disease must be penicillin-sensitive; (2) there must be adequate concentration of penicillin at the site of infection. Although the organisms mentioned as being present in the sputum of the case described above are likely to be penicillin-sensitive, this must first be confirmed, and this is especially important in the case of the non-haemolytic streptococci, many strains of which are resistant. The second condition would be very difficult to fulfil in the treatment of the case described. Intramuscular penicillin in such cases has proved very disappointing. If a bronchogram demonstrated the existence of a localized bronchiectasis, penicillin solution 10,000 units per c.cm. instilled daily into the trachea, as for a lipiodol examination, might be of value. If no localized bronchiectasis is present, a bactericidal mist containing penicillin as described by Mutch and Rewell (*Lancet*, 1945, **1**, 650), and breathed by the patient, would be the most hopeful line in penicillin therapy. Benefit, however, would probably be only temporary, and the technique is still in the experimental stage.

Sclerosing Solution for Inguinal Hernia

Q.—*What is the technique of treatment of inguinal hernia with sclerosing solutions? What complications occur, especially in the male? What is the relapse rate? Following failed treatment by injection, is operation made any more difficult?*

A.—Many solutions are recommended. As good as any is:

Butyn, 8 grains
Quinine and urea hydrochloride, 4 drachms
Sol. methylene blue 2%, 5 minims
Distilled water to 4 ounces.

Two c.cm. are used at a time and injected into the inguinal canal, starting at the internal ring. With the index finger of the left hand invaginating the scrotum lying in the inguinal canal, the needle can be directed with the right hand into the various parts of the canal. Injections take place every week for 12 weeks or even longer. At no time during treatment should the hernia be allowed to come down, as this would tear open the scar tissue built up by the injections. A waterproof truss should be worn day and night and even while bathing. The percentage of cures is claimed by Ignat Meyer, who originated the treatment in America, at practically 100. In spite of this the method is very slow to be adopted, probably because of the length of treatment. Subsequent operation is naturally more difficult, but not insuperably so. The main complication is an accidental injection into the sac or peritoneal cavity, with a brisk chemical peritonitis. Testicular atrophy is not recorded, but is a possibility. Infection of the injected area is very uncommon.

An alternative solution is that in general use for sclerosing haemorrhoids—5% of phenol in almond oil in 2-c.cm. doses.

Emulsifying Bases

Q.—*What is the formula of Halden's emulsifying base? Is the unguentum aquosum (B.P.) an emulsifying base, and, if so, can liquids be added to it? What is eucerin? Please suggest a useful all-round emulsifying agent, especially for scalp ointments.*

A.—Halden's emulsifying base (H.E.B. simplex) contains liquid paraffin, petroleum jelly, higher fatty alcohols, and their phosphated esters. It is freely miscible with water, and is recommended as an ointment base for all purposes. As it also mixes with exudates it is a suitable application for moist surfaces. Eucerin, a lanolin derivative, forms a stable emulsion with aqueous solutions up to 200%. Because of its hydrophilic nature it provides a suitable base for ointments used, for example, on moist mucous surfaces. Unguentum aquosum is a combination of the ointment of wool alcohols and water in equal parts (*B.P.*, Sixth Addendum) and is an alternative to petroleum jelly. The needs of the individual case decide the kind of ointment base or emulsifying agent required, and as these vary in accordance with differing circumstances no all-round emulsifying agent can be suggested.

Relative Infertility in Female

Q.—*What are the latest treatment and lines of investigation for relative sterility? A woman 39 years old has been married some 8 years, had a miscarriage at a few months 4 years ago, and since then has not conceived.*

A.—As a result of recent work on sterility, the investigation and treatment of such cases have become extremely complicated. The following routine is carried out in most clinics in this country. The fertility and potency of the husband are first established, and it is discovered if coitus is normal. A general examination of the wife is then made, to determine if there is any obvious general disturbance of the endocrine system. This is followed by a pelvic examination to exclude gross pelvic lesions, and examination of the cervix with a speculum to exclude any cervicitis; this is treated, if present, by cauterization. Next, the patency of the Fallopian tubes is tested by insufflation with carbon dioxide gas or iodized oil, the latter being followed by an *x*-ray examination of the pelvic organs. This test should be performed about 10 days after the onset of the menstrual period. If the tubes are patent a biopsy of the endometrium is taken with a suction curette, and without anaesthesia, a day or two before the expected onset of menstruation or on the first day of the period. Examination of the section thus obtained will provide evidence of ovulation.

If facilities for these tests are not available two possible lines of treatment may be suggested. Coitus should be timed so as to take place during the most fertile period in the menstrual cycle—that is, about the time of ovulation. This time may be estimated roughly by assuming that ovulation takes place about 15 days before the onset of the next menstrual period. It has recently been suggested that the time of ovulation may be estimated more accurately b taking the body temperature daily. It has been claimed that a brie fall of body temperature, followed by a rise, occurs at this tim It is recommended that the body temperature be taken per rectu (though some say that mouth readings are equally satisfactory before rising or taking any food or drink, in the morning. A similar, though sharper, fall of temperature precedes the onset o menstruation, but this does not take place if conception has occurre

Endocrine products are now widely used in the treatment o sterility, and the following scheme of treatment may be recommended. In a patient with a relatively regular 28-day cycle, follicle stimulating hormone from the anterior pituitary (usually derive from the serum of pregnant mares) may be given on the 8th, 10th and 12th days of the cycle, or a preparation containing a combination of follicle-stimulating and luteinizing hormone may be use and is claimed by some to be more effective. In addition, corpu luteum hormone (progesterone) may be given in doses of 5 mg. o the 19th, 22nd, and 25th days. If conception occurs, this may b continued twice weekly or oftener for the first three or four month of pregnancy.

LETTERS, NOTES, ETC.

Piling Pelion upon Ossa

Mr. W. **BARCLAY** (Huddersfield) writes: The series "Letters, Note and Answers" is usually interesting and instructive. The questio and answer on injury from mine explosion (*Journal*, July 21, p. 106 are certainly in the former category, and possibly in the latter, thoug not in the way intended by the respondent. I suggest that in futur you obtain answers to such questions from a member of the profession who (1) knows that "os calces" is not the plural of "o calcis," (2) has some knowledge of Newton's law that action an reaction are equal and opposite, (3) can stick to the point. I, ala can make little claim to learning, but, seriously, a reply such a this one is a reflection on the preliminary education of the write (and of the subeditor who passed it) and strengthens the opinio of the many (both inside and outside the profession) that the profession of medicine no longer deserves the title "learned."

⁂ H. W. Fowler defines pedantry "as the saying of things i language so learned or so demonstratively accurate as to imply slur upon the generality, who are not capable or not desirous of suc displays." To describe the heel bones as "ossa calcium" would we believe, be misleading as well as pedantic; and to escape thi verbal dilemma by writing "ossa calcis" would lead us int anatomical ambiguities. "Os calces" is an indefensible compromis which nevertheless has the attraction of simplicity and is likely t convey to the generality just what is meant. "Piling Pelion upo Ossa" was the Greek equivalent for "laying it on thick," Oss being a mountain in Thessaly between Pelion and Olympus.—ED *B.M.J.*

The Acquisition of Language by Infants

Dr. J. **WALKER TOMB** (Sydney) writes: In the *British Journal o Psychology*, July, 1925, I published a short article on the innat capacity of infants to understand spoken language. In that articl I endeavoured to establish that, in order that an infant may acquir the faculty of language, four things are essential: (1) It must b able to hear. (2) It must possess the gift of auditory memory t be able to recall the speech sounds used in its hearing. (3) It mus possess the necessary organs of articulation to enable it to reproduce the remembered sounds. (The development of the organs o articulation is normally a protracted process extending over sever years; *vide* Sheridan, *Journal*, May 19, p. 707.) (4) It must posses the innate capacity (which is a function of the subconscious intelligence) to attach the *intended* meanings to the spoken sounds. Th first three of these essentials (hearing, memory, and the organs o articulation) are possessed by parrots, which nevertheless neve acquire the faculty of language, because they lack the fourth essential—i.e., the capacity to attach the intended meanings to spoke sounds.

Types of Syringe Needles

Mr. S. J. **EVERETT** (Thornton Heath) writes: I have had my attention drawn to the extract printed in the *Journal* of June 30 (p. 932 answering a query from one of your readers. I am writing to yo as chairman of the committee sitting under the auspices of th British Standards Institution, who are considering the standardization of hypodermic equipment generally. The answer to the quer is a little ambiguous, as it is rather inclined to suggest that th committee have agreed the range of needles reproduced in th answer to the query. It also mentions Record, Luer, and S.I.M.A as being the standard cones. I think attention should be drawn t the fact that, whilst this part of the answer gives the present mos widely used standard, this has no relation whatsoever to the recommendations put forward to the British Standards Institution, whos findings have not yet been made public.

TRIAL OF WHOOPING-COUGH VACCINE IN CITY AND RESIDENTIAL NURSERY GROUPS

A REPORT TO THE MEDICAL RESEARCH COUNCIL

BY

A. M. McFARLAN, M.B., B.Ch. ELIZABETH TOPLEY, M.B., B.S.
(Emergency Public Health Laboratory, Oxford)

AND

MARY FISHER, M.R.C.S., D.C.H., B.Sc.
(Public Health Department, Oxford)

During the years 1942 to 1944 an attempt was made to assess the prophylactic value of a pertussis vaccine by comparing the fate of inoculated children with that of control children. In Oxford City the trial was run in conjunction with the Public Health Department; it comprised 327 inoculated and 305 control children, who were followed up for over a year after their last inoculation. During this time only sporadic cases of whooping-cough occurred. From Nov., 1942, onwards small but similar groups of inoculated and control children were observed in eight residential nurseries for evacuees. In four of these nurseries (Nos. 1, 2, 5, and 8) an epidemic of whooping-cough occurred some time after the inoculations were completed, enabling the experience of the two groups to be compared. The outbreak at one of these nurseries (No. 1) has already been reported (McFarlan and Topley, 1943), but for the sake of completeness it is included with three other outbreaks at Nurseries 2, 5, and 8, to be described now. The present report summarizes the evidence obtained using a total (English) dosage of 40,000 million organisms in Oxford City and two residential nurseries (Nos. 1 and 2), and a higher dosage at two other residential nurseries (Nos. 5 and 8). The investigation was carried out under the direction of the Whooping-cough Subcommittee of the Infectious Diseases Committee of the Medical Research Council.

The vaccine was prepared by Messrs. Burroughs Wellcome and Co. For the vaccine used in Oxford City and residential Nurseries 1 and 2 a mixture of three strains of *H. pertussis* in Phase I was employed, each of which had been grown for 3 days at 37° C. on a Bordet-Gengou medium containing 33% of horse blood. The growth was suspended in 0.5% phenolized distilled water, the function of the water being to lyse the horse-blood corpuscles in the vaccine. The suspension was filtered through muslin and allowed to stand for 7 days at 4° C. The haemolysed supernatant fluid was then discarded and the deposit washed once in 0.5% phenolized saline. The vaccine was suspended finally in 0.5% phenolized saline and standardized by Brown's opacity tubes to a calculated strength of 20,000 million organisms per ml. No heat was applied to the vaccine at any stage of the preparation; the organisms were both killed and preserved with 0.5% phenol. In the vaccine used at residential Nurseries 5 and 8 the organisms were killed and preserved with 1:10,000 merthiolate; in all other respects the preparation of the vaccine was the same as for the earlier batches.

It is important to point out that the methods used for the standardization of vaccines in this country and the United States yield grossly discrepant results. The reason for this need not be discussed here. It is sufficient to draw attention to the difference, which is clearly of importance in assessing the results of comparative trials in the two countries. Observations made at the Wellcome Physiological Research Laboratories (for an account of which we are indebted to Dr. H. J. Parish) showed that the Wellcome vaccine, stated on the label to contain a given number of organisms, was about four times as turbid as that of a Parke Davis vaccine from Detroit having the same labelled strength. Prof. G. S. Wilson (personal communication), who, in this laboratory, compared a number of batches of the Wellcome vaccine with batches of the Parke Davis vaccine, using both turbidity estimations and direct enumeration of the organisms in a Helber chamber under dark-ground illumination, found that by both methods the Wellcome vaccine was over three times as strong as the Parke Davis vaccine.

TABLE I.—*Methods of Inoculation and Time Relation to Whooping-cough Cases*

Place of Trial	Method of Killing and Preserving the Vaccine	Volume given at Inoculation				Time Interval between Inoculations	Total Dosage in Millions of Organisms*	Date of Last Inoculation	Time of Onset of First and Last Cases of Pertussis	Time Interval: Last Inoculation to Onset of First Case in Epidemic
		Inoculation Number								
		1	2	3	4					
Oxford	Phenol	1 ml.	1 ml.	0	0	4 weeks	40,000	Jan.–March, 1943	Cases observed Mar., 1943, to July, 1944	No epidemic
Nursery 1	„	1 ml.	1 ml.	0	0	„	40,000	Dec. 21, 1942	April 4, 1943, to end of May	4 months
„ 2	„	1 ml.	1 ml.	0	0	„	40,000	Jan. 1, 1943	Oct. 16, 1943, to end of Nov.	9 „
„ 5	Merthiolate	1 ml.	1 ml.	1 ml.	2 ml.	1 week between 1st, 2nd, and 3rd; 4 weeks between 3rd and 4th	100,000	Dec. 30, 1943	April 22, 1944, to middle of July	4 „
„ 8	„	0·5 ml.	0·75 ml.	1 ml.	0·75 ml.		60,000	March 15, 1944	March 28, 1944, to June 6	2 weeks

* As pointed out in the text, the figures given in this column would have been about three times as large if the vaccine had been standardized in the United States.

The vaccine was injected intramuscularly into one or other arm. If A.P.T. was given at the same time it was injected at another site. The volumes inoculated and the time intervals between the inoculations are shown in Table I. The total dosage of about 40,000 to 100,000 million organisms would probably correspond to an American dosage of about 120,000 to 300,000 million.

Although the time interval between the last inoculation and the first exposure of the children to whooping-cough ranged from 2 weeks to 9 months, and although in Oxford City 1 to 6 children in the investigation developed whooping-cough every month up to 18 months after the last inoculation, the number of cases was too small to justify any attempt at correlation between this interval and the incidence of whooping-cough among the two groups. It was not possible to obtain sera from the children for either complement-fixation or agglutination tests.

Reactions to the Pertussis Vaccine.—No severe reactions occurred in the children in Oxford City and residential Nurseries 1, 2, 3, and 4, where a total dosage of 40,000 million organisms was given. It was found impracticable in Oxford itself to get reliable information from the homes, but at each nursery a careful record was kept. At Nursery 1, for example, 10 out of the 12 children inoculated were reported to have had local reactions after their first but not after their second inoculation; only one was at all marked. There were no general reactions. On the other hand, the experience at Nurseries 5, 6, and 7, where another batch of vaccine was given in a total dosage of 100,000 million organisms, was disturbing. The general reactions were so severe as to condemn the further use of the vaccine in this dosage. Each of the 17 children inoculated developed a febrile reaction after the first inoculation. In two children the highest temperature recorded was 104° F. and 104.8° F. respectively, and the pyrexia lasted 7 to 10 days. The remaining children had temperatures of 99.4 to 101° F., which returned to normal in from 1 to 3 days. Pyrexial reactions (99 to 102° F.) followed each subsequent inoculation in all but one of the 14 children who received the full course. At the site of the inoculation the area of redness never exceeded 3 in. in diameter, and was generally less than this; but the local reactions did appear to disturb the children. For this reason when Nursery 8 was visited the dosage of vaccine inoculated was reduced to 60,000 millions; the reactions, however, both general and local, were enough to make the widespread use of this dosage undesirable.

The methods of selection of the inoculated and control groups, the evidence of their similarity, and the experiences of these groups are perhaps best described separately for Oxford City and for the residential nurseries.

The Oxford City Trial

The two series of children were chosen from those who were more than 6 months and less than 3 years of age on Jan. 1, 1943, who normally attended the infant welfare clinics or wartime day nurseries of the Public Health Department, and who had no history of whooping-cough or of inoculation against it. The majority of children had their consent forms signed and the first inoculation given at the same time as a normal visit to the clinic, and often at the same session as an A.P.T. inoculation against diphtheria. The propaganda was carried out not only at the clinics but also by the health visitors, who during their routine home visits persuaded the mothers to bring their children up to the clinics for whooping-cough inoculations. It therefore needed very little effort on the mother's part to have her child inoculated. The control children were chosen from the clinic record cards, which at each clinic were filed in order of the date of first attendance. For every child inoculated, a card was picked at random from the cluster of cards about the same place in the file as that of the inoculated child. The first card picked of a child of the same sex, approximately the same age, and with no history of whooping-cough or inoculation against it, was marked "Whooping-cough Investigation" and the child's name was included in the control group. The inclusion of a child in this group was not determined in any way by the circumstance that its mother had refused permission for inoculation.

The children attending wartime day nurseries were chosen separately. Those eligible in each nursery were divided according to age and sex into inoculated and control groups, using the same methods as described for the residential nurseries. When a child left Oxford or was inoculated against whooping-cough by a general practitioner it was excluded from the investigation. At the end of the period of observation there were 305 control and 327 inoculated children in the series. The nursery population had altered greatly.

Evidence of Similarity.—Some of the characteristics that might affect the incidence of whooping-cough were recorded in the two groups. χ^2 and χ_c tests (Fisher and Yates, 1943) were applied to the data to determine how far the differences in incidence might be considered to be the result of sampling variation. The differences in distribution of (1) number of children in family, (2) number of other susceptible children in family, (3) number attending day nurseries or nursery classes, (4) number suffering from measles before or during the investigation, were in no instance greater than could be accounted for readily by sampling variation. However, the frequency of prior inoculation with A.P.T. was significantly less ($P < 0.005$) in the control group than in the inoculated group (49% in the control group and 73% in the inoculated group had at the beginning of the experiment a history of A.P.T. inoculation). Fifty-one per cent. of the children in the control group and 89% of the children in the inoculated group, who had not received A.P.T. at the beginning, received it in the course of the investigation. Thus the frequency with which inoculated children were brought for A.P.T. remained consistently higher than that in the control group.

Since this difference between the two groups might have a bearing, as an index of maternal care, on the incidence of exposure to pertussis, the effect on pertussis incidence has been carefully investigated. There is a difficulty, in that all but 6 of the 89 inoculated children who had not received A.P.T. at the start of the investigation had received it at the end. In the control group 154 (50%) had not received A.P.T. at the beginning of the investigation, and 76 (25%) had still not received it at the end. Thus it is unlikely that any A.P.T. effect could be established in the inoculated group, and, in fact, the differences in incidence are well within sampling variation. In the control group, in which an A.P.T. effect might have been observed, there is an even smaller difference in relative frequency of the incidence of pertussis. No evidence was obtained that the A.P.T. distribution was relevant to the experiment.

So far as it is possible to judge, it appears that the two series of inoculated and control children were fair random samples of the susceptible Oxford clinic children between 6 months and 3 years of age.

Follow-up Observations.—These children were observed for 12 to 18 months, starting Jan. to March, 1943, and ending March to July, 1944. Observation of the inoculated children was begun 3 to 28 days after their last inoculation. The control children were selected and visited during the inoculation period, and their beginning of observation was made to correspond with that of the inoculated children. The date of the last observation was the date of the last visit to the home. A chart was compiled to show the number of inoculated and control children, and the number of cases of whooping-cough among them, for every month from Jan., 1943, to July, 1944. In no month was there any significant difference in the proportion of inoculated and control children. It follows that the average length of observation per child was the same in the two groups. Owing to shortage of staff it proved impossible to pay regular visits to the home of each vaccinated and control child in the series. Cases or contacts were visited by one of us (A. M. M. and later E. T.) as soon as possible after they were notified to the Public Health Department by the medical practitioners or by the health visitors. The notifications were necessarily often made late in the disease or even weeks later. In only 28 instances was it considered worth while taking a nasopharyngeal swab from a child in the investigation or from a member of its family who had definite whooping-cough. In only six of these cases was *H. pertussis* isolated. During the spring of 1944 each health visitor reviewed the history of every child on her list who was in the investigation, and in the majority of instances made the final visit herself. However, if there was a history of a suspicious cough or of whooping-cough or of contact with whooping-cough, or a special visit was required for further information, one of us made the final visit. In May, 1944, a list was compiled of every school or nursery that was attended by a child in the investigation and from which one or more cases of whooping-cough had been notified to the

Public Health Department. Each of these was visited once, and the teacher or matron told us which children in the investigation had been in the same class or room as a case of whooping-cough, and whether they had developed pertussis. In a few cases notified for the first time a home visit was made.

The evidence obtained by this method of follow-up is summarized in Tables II and III.

TABLE II.—*Incidence of Whooping-cough among Children exposed to a Case in the Same Room of a Day Nursery or Nursery Class in Oxford City*

	Inoculated Children	Control Children
Number of children exposed	29	25
Number of children developing definite whooping-cough after exposure	5	6
Proportion developing definite whooping-cough after exposure	17%	24%

Statistical analysis of these data shows that there are between 5 and 7 chances out of 10 of obtaining greater differences in the observed frequency of whooping-cough in two similar samples drawn from such a uniform population.

Evidence of Exposure to Whooping-cough.—The monthly record of cases showed no evidence of an epidemic during the investigation. A history of exposure to whooping-cough was obtained more frequently from the mothers of inoculated children than of control children. Thus it appeared from the home-visit data that 27 inoculated and 20 control children had been exposed to whooping-cough in the same house for more than one day. A history of less intimate exposure was obtained from the parents of 36 inoculated and only 14 control children. In the nursery classes of schools and in day nurseries (Table II) there was no significant difference in the frequency of exposure. The evidence from mothers whose children had been inoculated might well be more reliable than that of the mothers of the control children, who did not understand their connexion with the investigation. In the nursery classes and nurseries the same teacher or matron observed a large number of children. The teacher generally knew nothing of the difference between inoculated and control children, whereas the matrons had assisted in the original planning of the experiment and understood clearly the importance of treating them alike. For this reason we should be disposed to pay considerably more attention to the data obtained from the nurseries and schools than from the mothers.

TABLE III.—*Incidence of Whooping-cough, Regardless of History of Exposure, Among All Children in the Investigation*

	Oxford City		Residential Nurseries	
	Inoculated Children	Control Children	Inoculated Children	Control Children
Number of children observed	327	305	33	30
Number of cases of definite whooping-cough	41 (30)*	43 (29)*	18 (15)*	19 (19)*
Number of cases of doubtful whooping-cough	10	6	5	3
Proportion of children with definite whooping-cough	12·5%	14·1%	54·6%	63·3%

* The figures in brackets represent the numbers of definite cases of whooping-cough which both whooped and vomited.

Statistical analysis shows that the probabilities of obtaining more widely different frequencies in two samples from the same population are 0.5–0.7 for the Oxford City samples and 0.3–0.5 for the residential nursery samples.

Evidence of Incidence of Whooping-cough.—This evidence is clinical, not bacteriological. Its only claim to uniformity is that the diagnosis was decided by home visits made by the same person, who used the same method of approach to inoculated and control children. The original notifications were, as stated above, made by general practitioners and health visitors. Each health visitor had approximately equal numbers of inoculated and control children on her lists, and appreciated the importance of treating them alike. It can be seen from Table III that the frequency of clinically definite cases of whooping-cough was similar in the inoculated and control groups of children. It is more difficult to assess accurately the incidence of whooping-cough among children with a history of exposure to the disease. We have reason (see above) to doubt whether the mothers of inoculated children gave reports comparable with those from mothers of the controls. For this reason Table II presents the evidence for the incidence of cases among children exposed in nursery classes or day nurseries only. The differences in incidence of whooping-cough—first, between all the inoculated and all the control children, and, secondly, between the small numbers of inoculated and control children known to be exposed to whooping-cough in day nurseries or nursery classes—can be accounted for entirely on the basis of sampling variation.

Although in each case a note was made of the maximum number of whoops per day and the presence or absence of vomiting, the results depended on the, often distant, memory of a wide variety of mothers and cannot be regarded as reliable. Most cases were mild. Only four were complicated by pneumonia—two in inoculated and two in control children.

The Residential Nurseries

The methods of selecting the inoculated and the control groups, the evidence for their similarity, and the experience of these groups will be discussed for all four nurseries together. These nurseries, all in the home counties, are housed in mansions used temporarily for the care of evacuee children. Each is an isolated community cared for by a residential staff. some times aided by daily helpers.

In each nursery every child from 6 months to 3 years of age who had no history of whooping-cough or of inoculation against it was included in the trial. At Nurseries 5 and 8 the upper age limit was raised to 4 years in an attempt to get larger groups of children. The eligible children were divided into two groups of almost equal age and sex distribution. In Nurseries 5 and 8 it also proved necessary to ensure an even distribution of the two groups in the same room or unit—in Nursery 5 because of a suspected case of whooping-cough at the time of the first inoculation, and in Nursery 8 because of the greater degree of segregation. If the mother of a child selected for inoculation refused to give her consent the child was placed in the control group and a corresponding "control" child selected for inoculation instead. In each residential nursery the two groups of children were similar in every respect except inoculation. For months or years they were cared for and fed by the same staff and exposed to the same risks of infection.

When whooping-cough was reported in a residential nursery it was visited at once, and thereafter at weekly to monthly intervals throughout the epidemic.

The evidence of equal and definite exposure to whooping cough was very much more reliable than is possible among children living at home. In each outbreak *H. pertussis* was isolated from at least one child with clinical whooping-cough. At every visit the matron told us of the dates that any child had been moved from one room to another. It was clear that in each of the four nurseries all the selected children had been exposed to a whooping-cough case that had lived and slept in the same room while in the catarrhal and paroxysmal stages of the disease.

The evidence for the occurrence of whooping-cough was also more reliable than is possible among children living at home. The children were observed throughout by the same staff and by the matron, who, each time we visited the nursery, gave us the clinical details which she had collected for all the children in the investigation. The findings are summarized in Table III. The cases were nearly all mild. Two cases in Nursery 8 and one case in Nursery 2 were considered more severe by the matrons. These were control children. The evidence obtained on the maximum number of whoops per day was necessarily less reliable and showed nothing significant. Only one child showed marked loss of weight during the illness. This was a control child who developed a dubious pneumonia. No other complications occurred.

These facts, together with the data in Table III, emphasize the smallness of the figures on which any conclusion from the nursery material must be based. All that can be said is that the difference in the incidence of whooping-cough in the inoculated and control groups can be accounted for entirely on the basis of sampling variation. No satisfactory evidence was obtained that the vaccine was of any value in modifying the course of the disease.

Discussion

The Oxford City evidence has the advantages and disadvantages of a city field trial. These have already been discussed. The results show that the pertussis vaccine in a total (English) dosage of at least 40,000 million organisms did not significantly affect the incidence of whooping-cough. In the residential nursery trials the groups were almost identical in constitution and risk of exposure to infection, and the clinical data were more reliable, but the number of children under observation was necessarily much smaller. The results, however, bear out the findings in Oxford City that the vaccine was of no value in preventing whooping-cough.

Doull and his colleagues (1939) have already recorded results almost as disappointing as our own; but the majority of the reports from the United States and Canada suggest that vaccination against pertussis is effective. Although it is possible to find faults with points in the planning or statistical analysis of some of the trials it is difficult to avoid the conclusion that vaccination conferred some protection. It is noteworthy that most of these trials were carried out in clinic populations in which it is extremely difficult to obtain perfect equalization of the inoculated and control groups, particularly in regard to exposure to infection. In one of the few trials conducted in residential institutions, where a far greater degree of similarity can be attained between the two groups, little or no success was claimed (Siegel and Goldberger, 1937).

Our own results may be criticized on the ground that the vaccine was of insufficient antigenic potency or that the dosage employed was too low. Examination of the data recorded by different observers who have apparently been successful in whooping-cough prophylaxis shows that a wide variety of vaccines has been used, and there is little to suggest that any one method of vaccine preparation is greatly superior to any other. In respect of dosage, we have already pointed out that there is a gross discrepancy between the results yielded by the methods of vaccine standardization in this country and the United States, and that if our vaccine had been prepared in an American laboratory its strength would have been estimated at about 60,000 millions instead of 20,000 millions per ml. It is probable, therefore, that our total dosage was higher than that used in any of the investigations recorded in Canada or the United States. This is borne out by the severity of the reactions that we obtained after inoculation of the larger doses of vaccine.

Since the possibility could not be excluded that the Wellcome vaccine used in our investigations differed in some material way from vaccines prepared in the United States and Canada, it was decided by the Whooping-cough Subcommittee of the Preventive Medicine Committee of the Medical Research Council to carry out a fresh investigation in which a vaccine of American origin was used. Such a trial is now being undertaken in Oxford, under carefully controlled conditions, using a vaccine manufactured by Messrs. Parke Davis of Detroit to the formula of Dr. Sauer, of Evanston, Ill. The results of this inquiry will, it is hoped, be published in due course.

Summary and Conclusions

Over 600 susceptible children of 6 months to 3 years of age attending welfare clinics and wartime day nurseries in Oxford City, and 110 evacuee children of 6 months to 3 or 4 years of age distributed in eight residential nurseries in Oxfordshire, Berkshire, and Buckinghamshire, were divided into "inoculated" and "control" groups by methods designed to render the two groups similar in every respect other than inoculation.

The inoculated children were given either two doses of pertussis vaccine at a 4-weeks interval, or four doses at intervals of 1, 1, and 4 weeks. The total dosage ranged from 40,000 to 100,000 million organisms, corresponding to an American dosage of about 120,000 to 300,000 millions.

Whooping-cough occurred sporadically in Oxford City during the succeeding 18 months, and broke out in four of the residential nurseries 2 weeks to 9 months after the last inoculation.

No significant difference was observed in the incidence or severity of whooping-cough between the inoculated and the control children. In Oxford City 12.5% of 327 inoculated and 14.1% of 305 control children developed definite whooping-cough. In the residential nurseries the corresponding figures were 55% of 33 inoculated and 63% of 30 control children.

The evidence obtained from this investigation lends no support to the view that pertussis vaccine is of value in the prophylaxis of whooping-cough; and it is suggested that the use of this vaccine should be discontinued till some positive evidence of its value is obtained in further carefully controlled trials.

We are indebted to Dr. R. B. Fisher for statistical advice; to Dr. G. C. Williams, Medical Officer of Health, Oxford C.B., for permission to carry out the investigation among the children under his care; to the medical officers and health visitors on his staff for their co-operation and active help; to Dr. E. Donaldson, Principal Regional Medical Officer, for his assistance in the choice of suitable residential nurseries; to the Waifs and Strays Society, the Margaret Club Day Nursery, the Whitefield Day Nursery, and the county councils of Buckinghamshire, Berkshire, London, and Oxfordshire, for permitting us to visit these nurseries; to the medical and nursery staff of each nursery we selected, particularly to Dr. J. A. Hill, Dr. G. N. Stathers, Dr. G. R. N. Henry, and Dr. N. Black; and to the Matrons of Cottesford House, Culham Court, Waddesdon Manor, and the Margaret Club Day Nursery for the collection of much of the data we needed. We particularly wish to thank Messrs Burroughs Wellcome and Co. for the free supply of vaccine.

PROBLEMS OF NAVAL WARFARE UNDER CLIMATIC EXTREMES*

BY

MACDONALD CRITCHLEY, M.D., F.R.C.P.

Senior Neurologist, King's College Hospital; Physician to Out patients, National Hospital, Queen Square

PART III.—LECTURE II (*continued*)

Psychological Effects of Long Service in the Tropics

A common opinion in the Tropics is that after about a year there is a noticeable deterioration in drive, alertness, keenness, memory, the capacity and speed of thought, and power of making decisions. These symptoms may be accompanied by an obvious lassitude, procrastination, irritability, sometimes bibulousness, and slovenliness in personal appearance. The better-educated are conscious of their own declining efficiency, and they note the same change in others; that is to say, the phenomena are both subjective and objective. The symptoms are popularly ascribed to the climate, whether hot and humid or hot and dry, and the point of view is freely ventilated that one to two years should be the maximum tenure in uncongenial tropical regions.

Since we are waging a naval campaign in equatorial waters, the problem has many important bearings. Medical advice is needed on several points. Do, in fact, changes in intellect or personality follow long tropical residence? If so, what is their nature?; how can they be prevented or alleviated?; what is the optimum duration of tour in the Tropics?

A new-comer may be struck by certain personality traits in some who have served for a time on a tropical station—traits made up of undue irritability, alcoholic indulgence, mild hypochondriacal preoccupation, and a tendency towards paranoid feelings of resentment. Castellani applied the term "cacophoria tropicalis" to a state of lassitude and mild general malaise. Whether actual falling off in performance and intellectual capacity exists we do not know for certain, but we suspect it. To determine the nature of this clinical picture is important. Superficially, the syndrome might strike one as representing a mild dementia with some personality deterioration were it not for the victim's clear insight and the fact that the condition is apparently "cured" after leave at home. More probably it belongs to the realm of the neuroses, with hysterical features motivated by a strong if thinly veiled desire to return home: in other words, a nostalgic reaction.

---

* Being the Croonian Lectures delivered to the Royal College of Physicians, July 10 and 12, 1945.

One must not assume that hot climate is the sole cause of this picture. The total situation must be visualized. Service factors such as boredom, isolation, lack of amenities including beer and familiar diet, home worries—financial or marital—all these occur and may outweigh the hazards of enemy action. Add the stresses and strains of disordered sleep, fatigue, bodily discomfort (perpetual sweating, skin irritations, diarrhoea, flies); and also the constant association with coloured folk and a growing intolerance of their inexplicable habits.

From a Service standpoint it is important to decide how much of this "tropical neurosis" is due to these auxiliary factors, some of which could perhaps be alleviated, and how much is due directly to climate. Though the literature upon this subject is growing, it is inadequate. Many tropical practitioners who have written upon the matter have not been psychiatrists, while the psychiatrists have not always had tropical experience. Of late there has been a tendency to decry the tropical neuroses and to minimize the part played by climate, as opposed to the many auxiliary factors.

The climatic factor would be supported if one could demonstrate: (1) that the same psychiatric features occur in tropical civilians whose homes and families are on the spot, having elected freely to take up a career in hot climates; (2) that nervous and mental symptoms do not occur when individuals live in artificially cooled quarters in the Tropics or when they have frequent spells up-country; (3) that the characteristics of the clinical picture are unlike those in neurotics at home; (4) that meteorological and clinical fluctuations run parallel; and (5) that the efficiency and the personality of tropical indigenes alter when they emigrate to a cool country. How far are these things possible?

1. It is difficult to escape the conclusion that neurotic symptoms are commoner in the Tropics than at home, though the incidence may be less in civilian than in Service personnel. There is agreement that loss of efficiency does gradually develop in the Tropics with time, that it is improved by leave in hill stations or in the United Kingdom, and that the civilian psychiatric picture resembles that seen in the Forces. That efficiency deteriorates is shown by the practice of the Colonial Office, and various banks and trading concerns, who have found that it pays to make compulsory long and frequent spells of leave at home.

Statistics reveal a high incidence of nervous or mental breakdown among civil servants in East and West Africa. Thus, psychiatric disorder was responsible for one out of every three invalidings from East Africa, and one out of every 2.7 from West Africa. Alcoholism was responsible for one out of every 24 and 30 respectively. (Tropical disease proper accounted for 1 out of 9 and 1 out of 10 respectively.) Of the deaths, 1 in 6 and 1 in 3.8 were directly due to tropical affections in East and West Africa, while 1 in 11 and 1 in 13 were suicides (see Table). These high figures, be it noted, apply to carefully selected Europeans who had chosen a career within the Tropics.

	East Africa							West Africa						
	Invalidings				Deaths			Invalidings				Deaths		
	Total	Trop. Dis.	N.P. Dis.	Alcohol	Total	Trop. Dis.	Suicide	Total	Trop. Dis.	N.P. Dis.	Alcohol	Total	Trop. Dis.	Suicide
1930	25	6	6	1	23	6	2	50	7	21	—	23	5	1
1931	29	3	15	1	24	6	1	48	2	21	4	37	15	3
1932	22	2	7	—	16	5	2	31	2	9	1	13	2	1
1933	23	2	4	—	18	1	3	40	5	12	1	15	6	1
1934	27	2	8	1	16	3	—	41	6	17	1	20	6	3
1935	16	2	3	1	19	6	2	37	4	14	1	15	2	2

Total ..	241	26	80	10	224	38	20	390	37	143	13	197	52	15

N.B.—The cases of alcoholism are included within the totals for neuropsychiatric (N.P.) disorders.

Of 166 psychotic American soldiers in 1901, 120 were stationed in the Philippines and the rest in the United States; the following year the number was 114 out of 186. In 1903 the suicide rate for the U.S. Army at home was 7 per 100,000 and in the Philippines 16 per 100,000 (C. E. Woodruff).

2. No figures are yet available as to the incidence of neurosis before and after the air conditioning of homes and offices in the Tropics, though it has been shown that the output of work is considerably speeded up after the installation of cooling plants.

3. In some respects the tropical syndrome differs from the usual neurotic pattern. The earliest and prominent features of the tropical neuroses are intense irritability, poor memory, and mental and physical lassitude, while the characteristic anxiety and depression so common in our experience at home are much rarer and appear later. Then again, the frank psychoses of the Tropics show a certain bizarrerie in their picture. Nothing like the Malayan *latah* and *amok* can be found in our mental hospitals, though the cause may be racial rather than environmental. The same applies to the *koro* of the Celebes islanders and the *uas-uas* of the Tripolitanian Arabs. But among white troops in the East special clinical entities are sometimes described—the amoebiasis psychoneurosis, the depression of the rubber plantations, the mepacrine psychoses—though in all cases the suggested aetiology is dubious and the status of the syndrome insecure. Queer explosive and violent outbursts with confusion and subsequent amnesia occur on occasion among European troops in the Tropics, but they are not so much attributable to the climate as to the taking of native spirits—*arak, zebib, lagbi,* or *buha.*

4. In tropical and subtropical areas spells of inclement weather may cause great discomfort and exaggerate whatever psychiatric features already exist. This is illustrated by the hot dry winds of high velocity. Dexter noted that Denver school-children were more unruly when strong southerly winds were blowing. The *mistral* of the South of France is said to produce a curious irritable state—*le cafard.* In Libya and the Levant there is the *khamsin,* in West Africa the *harmattan,* and in Malta the *xirocco*—all of which are climatic phenomena directly associated with psychiatric anomalies.

5. When Indians, Chinese, and negroes take up residence in a cooler part of the world their capacity for efficient mental work probably improves. This idea is supported by M. MacKinnon, who has studied the intellectual growth of European children born or reared in Kenya. At first they developed a mental alertness far superior to that of children at home, but after the age of 10 or so a gradual mental exhaustion and deterioration was the rule. These phenomena were in his opinion due to climate—to the stimulating effect of sunshine followed by the ill effects of undue heat. The circumstances were complicated, however, by the high altitude at which the children were living.

Psychological Effect of Long Service in Polar Regions

Naval ratings usually fare better in the extreme north than in the Tropics. Likewise, Scott's Antarctic team found the passage out through hot humid weather more trying than the cold climate which came later. We can, however, descry psychiatric features in the Arctic as in the Tropics, though possibly to a lesser extent. There are affective disorders which one associates with the solitude, darkness, and icy cold of the long polar winters. According to Burton, melancholy might result from lying "in stoves and caves half a year together in Iceland, Muscovy, or under the Pole itself." Explorers have noted these manifestations. We recall the "barrack-fever" of the German Forces occupying the most northerly part of Norway. The Finns speak of a Värtrotthet, or "spring-tiredness," which comes on towards the end of the winter season. Then there is the "light hunger" described in Russia by Katz and the "sun-thirst" of Goethe. It is interesting that depression is the dominant symptom in these Arctic disorders rather than irritability or forgetfulness as in the tropical neuroses. Similarly the incidence of manic-depressive psychosis among the insane population of Iceland far outnumbers that of schizophrenia; the reverse is true of Norway, where the racial stock is similar but the climate different. Mental disorders of the Tropics are reflected in the extreme north by a number of strange psychotic states. Thus we have the *piblokto* of the Greenlanders, with its impulsive features; the Siberian *mirvachet,* with its coprolalia and mimetic symptoms, so similar to the Malayan *latah*; and the Labrador *wihtiko,* with its cannibalistic urges.

Again, we find in the Arctic the same explosive alcoholic episodes which are encountered in the Tropics. Bouts of berserker violence may follow sudden intemperance among the inhabitants of such "dry" countries as Iceland. As regards personality, the indigenous elements of the Arctic regions display apathy, slowness, and inefficiency just as in the Tropics. But the Eskimos and the northern Siberians are said to improve considerably in activity when transferred to a more habitable climate, as in the United States.

The conclusion would seem to be that climate *per se* can at times be held responsible for personality changes, and that it may precipitate neurotic or even psychotic breakdown in certain predilected individuals; that it influences the pattern of the resulting clinical picture; and that it may, as Montesquieu taught, be one of the factors in determining the characteristics of the native population.

From a Service point of view there are certain practical lessons which will serve to avert breakdown of mental health in climatic extremes. These comprise the principles of (1) selection of the suitable and rejection of the unsuitable candidates for Arctic and tropical service; (2) determination of the most desirable limits of stay in such regions; (3) periodic leave periods in equable and agreeable environments; and (4) a complete welfare service in the fullest sense of the term, to maintain the comfort, spirits, interests, and morale of Forces serving in these exceptional circumstances.

Selection of Personnel Best Fitted for Tropical or Arctic Service

Artificial acclimatization has the incidental merit of directing attention to those who are unlikely to endure climatic extremes. Service requirements demand that the question of selection and rejection should be considered more fully. It must be realized that this practice does not yet stand upon the firm basis of an exact science. Further work in this direction is sorely needed not only for Service purposes but also for post-war Colonial development.

Some of the circumstances which cause an examiner to look askance at a candidate for foreign service are more significant than others. The contraindications for tropical and Arctic service may be regarded as either relative or absolute.

Contraindications

State of Physical Health.—Nothing is gained by listing the diseases which would afterwards preclude service in the Tropics or the Arctic, nor those minor and chronic maladies which are apt to flare up and become troublesome under extremes of temperature. This aspect of the problem is fairly well established.

Age.—The elderly do not tolerate heat or extreme cold as well as younger persons, especially if submitted to such a climate for the first time. Many would like to enforce an upper age limit of 35, or even of 30, upon those to be drafted to the Tropics or the Arctic. This may be too drastic, for the older sailor may have endured a hardening process in climates of another sort which may prove a good training for the immediate task. Scott's Antarctic expedition illustrates how well the rather older subjects can fare. His final Polar party consisted of five men, their ages ranging from 28 to 43. In his last letter Scott wrote: "*I want to tell you I was not too old for this job.* [He was 43.] *It was the younger men that went under first.*"

Body Build.—Tropical exigencies are less well tolerated by those of pyknic habitus than by the spare or by the tall lean types. When working in humid atmospheres a big man is perhaps at a disadvantage compared with a small one, for both will produce heat in proportion to their weight and dissipate it according to the ratio of body weight to surface area. Such was the case in S. Robinson's comparison of two subjects, but J. Weiner's analysis of over 200 miners showed only a slight correlation between heat tolerance and surface area. A poor musculature is not a handicap. In the case of cold climates, a generous amount of subcutaneous fat is of benefit, short of a pathological obesity with its attendant circulatory strain. Apart from the factor of fat-insulation, big persons on the whole tend to endure cold better than the small, just as the larger mammals are the ones to survive in the Arctic. Exceptions occur, of course, as in Scott's party, where they found "strength of will" more significant than physical constitution.

Physical efficiency tests might be most helpful if standardized. A step test has proved useful in the selection of recruits, and correlates well with subsequent performance in the heat. The virtues of any selection procedure which reproduces closely the actual conditions of work are obvious, and should be developed further.

Pigment.—There is some relationship between the pigmentation of an individual and his tolerance towards tropical life, though few would go all the way with Woodruff, who said that recruits for tropical Service should be limited to brunettes of short stature—the Mediterranean type, in fact. This same author tried to demonstrate a predominance of the blond in cooler climates and of the dark-skinned in the heat. Regarding sailors as essentially encompassed by a low-temperature environment (which of course is not the case), Woodruff has written: "*The blond type of man is now and always has been the best sailor. He takes to water like a duck . . . he is the yachtsman of the world, the boat-builder, and rules the sea at the present time.*" For Arctic service, cutaneous pigment is unlikely to influence the selection test, despite Woodruff's beliefs.

But certainly tropical Service is not for those who have such congenital defects of pigment as leucodermia. Albinos fare very badly in hot climates, and those rare cases of albinism in coloured people seldom attain adult age. Vitiligo, if sufficiently extensive, is a handicap. Persons who are of excessive or "platinum" blondness, especially if showing a tigroid fundus on ophthalmoscopical examination, are doubtful candidates for the Tropics.

Even the red-heads are suspect by virtue of their cutaneous intolerance towards the sun's rays. It has been said that the French Foreign Legion used to debar such candidates, but considerations other than photosensitivity might have been in mind.

Possible Biochemical Factors.—Experience both in the Tropics and in the far north shows that there are certain rare persons who are conspicuously intolerant of the heat, and others of the cold. Such heat-sensitive and cold-sensitive subjects are not conspicuous to ordinary medical tests; nor do they stand out by virtue of any feature of age, build, or colouring. It would be a convenience, at the very least, if it were possible to devise some test or criterion whereby these rare cases could be identified at home. No such hall-mark is known as yet, though a close physiological study is projected of all naval ratings who are invalided from the Tropics to the United Kingdom as being heat-sensitive. Alterations in the blood lipoid–phosphorus level and in the suspension stability test have been suspected, but not demonstrated, in such cases. It is possible that some inherent dysfunction of the sweat glands or of chloride metabolism, or both, may be a feature of the heat-sensitive. A fairly wide variation in the chloride content of the sweat is known to occur, but no serious attempt has yet been made to correlate the biochemical with the clinical data. The proportion of eccrine to apocrine glands may be significant in this connexion, as suggested by the known racial differences. Still more likely is a link between the total number and distribution of eccrine glands and heat tolerance. Unreadiness to sweat in hot atmospheres may be a factor in determining heat sensitivity. Thus Borchardt closed up 15 subjects for two to three hours in a hot room at 33° C. (91.4° F.), with a relative humidity of 90%. Seven of them sweated much less than the others, and these developed various distressful symptoms, their body temperatures rising considerably. Kuno regards those hypohidrotic persons as probably unsuited for tropical residence.

There are several possible causes of constitutional deficient sweating; there may be a relative insensitivity of the sweat centres in the hypothalamus, the medulla, or the spinal cord; or the sweat glands themselves may be abnormally sluggish in action or too few in number. With regard to the last point, it is important to note that those very rare persons with congenital absence of sweat glands should be absolutely precluded from the Tropics.

Sensitivity towards high temperatures may increase as the result of a previous attack of heat-stroke. For this reason, firms usually transfer an employee to the United Kingdom permanently on his recovery from such an illness.

The phenomenon of cold sensitivity exists in a small proportion of the population. Such display considerable distress and even syncope when exposed to low temperatures which would not incommode the average. B. T. Horton and G. M. Roth believe they can detect such cases in the laboratory. Five minutes' soaking of the hands in water at 8 to 10° C. (46.4 to 50° F.) will bring about flushing of the face, rapid pulse, and a fall in blood pressure. They believe that such can be desensitized in either of two ways: (1) by immersing the hands in water at 10° C. (50° F.) for one to two minutes twice a day for three or four weeks; or (2) by the subcutaneous injection of 0.1 mg. of histamine twice a day for two to three weeks.

An acquired sensitivity to cold may develop in those surviving severe exposure—as, for example, sailors who have been immersed for long periods in the sea or who have been adrift in waterlogged boats. A local hypersensitivity to cold is, of course, one of the characteristic sequelae of immersion-foot.

Psychological Factors.—It is certain that both tropical and Arctic regimes impose a psychological burden which may prove too heavy for some. On the whole, one would prefer the volunteer to the impressed man, though there may of course be a psychopathological motive for electing to serve in adverse climates. The psychopath and the unstable do not withstand the hardships of foreign service so well as those of placid and equable disposition. Those of poor intelligence or educational resource do not tolerate the boredom of some isolated tropical and Arctic appointments. Ratings with a bad crime record either in the Service or in civil life are most unsuited. The older practice of transferring the persistent offender to some remote and uncongenial station in the Tropics has proved intolerable. A previous severe neurotic breakdown is a relative disqualification, while any alcoholic tendencies should be regarded as an absolute contraindication both to tropical and to Arctic service.

Peacetime Implications

Warfare in hostile climatic conditions has compelled scientists to direct their attention towards protecting personnel against the exigencies. The lessons of war medicine hold out considerable promise for the post-war period. One has in mind the enormous expanses of our Empire which are at present underpopulated. The extension of air routes over the North Pole, the mineral resources of northern Canada and the Antarctic, the development of desert Australia and of the West Coast of Africa are problems for the future.

Tropical and Arctic disease are capable of control, and the way is open for further advances along these well-trodden paths. But there still remain the hazards and discomforts of extreme cold and heat. If men must fight in such environments it should be made possible for them to live and work there and raise families without the fear of swelling the "poor white" community.

Of the polar wastes we have the opinion of the explorer, Cherry-Garrard, that the Antarctic "is not half as bad a place for public service as the worst military stations on the Equator." But serious doubt has been expressed as to how far the Tropics can be developed. Balfour has said that under existing circumstances the white man in the Tropics is never more than a wayfarer or a sojourner. The Tropics, according to Carthew, are peopled by only three classes of European—the adventurer, the missionary, and the beachcomber—of which only the last makes the grade. While Dill believes that man can be made to thrive in desert wastes, the hot humid regions near the Equator have been suspected by such writers as Castellani, Huntington, Anderson, and Balfour as being wholly unsuited for European occupation in the present circumstances. Contrary views have been expressed by Cilento, Rohrbaugh, Gorgas, and others. The last believes that if malaria and sleeping sickness were stamped out, then the Congo could be colonized by the white race. The significant phrase is "in the present circumstances," because the eradication of disease, the new insecticides and repellents, air conditioning, and the free use of refrigeration have quite altered the problem of tropical habitability.

We can discern the need for a central Academy of Geomedicine or Climatology, wherein all research—medical and scientific—could be undertaken concerning both extremes of temperature. The fighting Services, colonization, geographical survey, agriculture, industry, communications, housing, would all be concerned. The first function would not be a study of disease states but of the physiology and psychology of performance, growth and fertility, vital statistics, textile research, protection of material against tropical and Arctic deterioration, and a fuller inquiry into ventilation, with a study of the influence of air conditioning upon human oecology. The Admiralty has under consideration the formation of a Tropical Research Unit, which could be regarded as the first move in this direction.

Conclusion

Let us conclude with two quotations as to the possible future development of unpropitious regions. Johnson in 1813, believing that man is better adapted than any other animal for migration from a northern to a tropical region, or the reverse, wrote: "*For this boasted prerogative, man is perhaps more indebted to the ingenuity of his mind than the pliability of his body. . . . Man, by the exertion of his mental faculties, can raise up a thousand barriers round him, to obviate the deleterious effects of climate on his constitution.*" The second quotation is from the geographer, Huntington: "*I want to know beyond question whether white man can live permanently in a tropical country, conquer the diseases, and make progress, without the help or hindrance of any coloured race. . . . I do not doubt the ultimate triumph of the white man over the Tropics, and much less do I despair of a white Australia. The process of selection for climate has never been really tested. All that has happened thus far has been purely fortuitous. The hope of the future, I believe, lies in an orderly and far-sighted selection of the right types of people, as well as in the further development of tropical medicine and hygiene.*"

To these ideas we would now also add the elaboration of an artificial climate in which to live and work.

My thanks are due to the Medical Director-General of the Royal Navy, Surgeon Vice-Admiral Sir Sheldon F. Dudley, for kind permission to publish these Lectures; and to Sir Edward Mellanby, chairman of the Royal Naval Personnel Research Committee, a body to which the Service owes so much, but whose activities cannot as yet be told in full.

PRESERVATION OF HUMAN SPERMATOZOA AT LOW TEMPERATURES

BY

A. S. PARKES, Sc.D., F.R.S.

(From the National Institute for Medical Research, Hampstead)

Several experiments have been carried out, in the last few years, on the preservation of spermatozoa at low temperatures. This work is clearly in its early stages, but already very significant observations have been made on human as well as on avian and amphibian material. Luyet and Hodapp (1938) reported that a large percentage of frog spermatozoa showed motility after being partially dehydrated in 2 M-sucrose, spread in a thin film on a mica slip, immersed in liquid air, and thawed rapidly by plunging into medium warmed to 20° C. The technique of these authors was similar to one which had been successful with plant tissues, and was based on the assumption that the essential condition for survival of the spermatozoa was instantaneous freezing, to secure vitrification rather than crystallization of the water, and instantaneous thawing. Partial dehydration, by the addition of laevulose, was also used by Shaffner, Henderson, and Card (1941), who found that about one-third of fowl spermatozoa could be revived after freezing at −79° C. Duration of freezing, up to 14 months, was not an important factor in survival rate. Spermatozoa revived after one hour at −79° C. were capable of effecting fertilization; but there was very early embryonic death (Shaffner, 1942).

In view of these results the discrepant experiments recorded in the literature dealing with human spermatozoa are of great interest. As long ago as 1897 Davenport recorded that human spermatozoa would survive freezing at −17° C. This interesting observation received little attention for many years, but in 1938 Jahnel found that a proportion of human spermatozoa could be revived after freezing in glass tubes for 40 days at −79° C., or for shorter periods at −196° C. and −269° C. Jahnel does not state the diameter of the tubes used, but he did not apparently take any special precautions to ensure the utmost rapidity of freezing and thawing. Shettles (1940) froze human semen in glass capillary tubes 0.2 mm. in diameter, and obtained a low percentage revival of the spermatozoa from −79° C., −196° C., and −269° C. A few spermatozoa revived after 70 days at −79° C. Shettles emphasizes the importance of the freshness of the specimen. Hoagland and Pincus (1942), following up the premises of Luyet and Hodapp and using liquid nitrogen, tried an elaborate series of devices to facilitate the instantaneous vitrification and thawing of human semen. However, except in one or two isolated experiments, the revival rate was very poor. No spermatozoa could be revived after vitrification in fine capillary tubes.

The results of Hoagland and Pincus are in strange contrast to those of Jahnel, whose work is not cited by the American authors, and the discrepancy shows that other factors than mere rate of vitrification and thawing have to be considered. From a practical point of view, the question is of some importance. Jahnel's results suggested that the prolonged storage of human semen at low temperatures might be possible; the results of Hoagland and Pincus, on the other hand, offered no such prospect. The experiments described below were therefore carried out on the low-temperature preservation of human spermatozoa.

Technique

Semen was obtained from several different donors; all specimens were rated normal by the usual seminological examination. No marked difference in resistance to freezing was noted between the different samples. The semen was allowed to liquefy before being used, and was not diluted. In experiments with capillary tubes the semen was allowed to rise in the tube and the end was then sealed. Unless otherwise stated, immersion in the freezing medium was always for one minute, thawing being done by transferring the film, tube, or ampoule as rapidly as possible to medium or water at 37° C. Freezing fluids, other than liquid nitrogen (−195.8° C.), were made by cooling ethyl alcohol with solid CO_2. Quart-size vacuum flasks were used as containers.

Results

In a preliminary experiment a comparison was made by immersing semen in liquid nitrogen (*a*) as a thin film in a platinum loop, (*b*) in a very fine capillary tube (internal diameter approximately 0.15 mm.), (*c*) in a coarse capillary tube (internal diameter approximately 0.5 mm.), (*d*) in thin glass tubing (internal diameter approximately 1 mm.). After thawing, no motile spermatozoa were seen in the semen from (*a*) or (*b*); they were abundant in that from (*c*) and (*d*). A repeat experiment gave similar results. It seemed, therefore, that the results both of Jahnel and of Hoagland and Pincus were reproducible, and considerable doubt was cast on the idea that speed of freezing and thawing was the primary factor in the survival of human spermatozoa. A more extended experiment was carried out in which the temperature of freezing as well as the bore of the container was varied. The results are given in the accompanying Table. Although survival at −20° C. was not prolonged, these results give little support to the view of Luyet that freezing under conditions leading to the formation of ice crystals is incompatible with the survival of the spermatozoa, but they confirm the previous result that some inimical factor is associated with freezing in a very fine capillary tube. The nature of this factor is not clear, though a surface effect of some kind seems to be indicated. Pressure as such is not likely to be involved, since Marsland and Rugh (1940) showed that spermatozoa are unaffected by hydrostatic pressure.

Table showing Revival of Human Spermatozoa After Exposure to Low Temperature for 1 Minute or 5 Hours

Temperature	Freezing for 1 Minute in Capillary Tubes of Diameter of			Freezing for 5 Hours in Capillary Tube of Diameter of 1 mm.
	0·15 mm.	0·5 mm.	1 mm.	
− 20° C.	0	+	+	0
− 79° C.	0	+	++	++
− 196° C.	0	++	++	++

0 = No revival. + = Some spermatozoa revived. ++ = Abundant spermatozoa revived.

In view of the successful results obtained with comparatively wide tubing attention was turned to the use of ampoules, and 1 c.cm. of semen was frozen at −196° C. in an ordinary 5-c.cm. pyrex ampoule. On thawing out, numerous active spermatozoa were seen in the sample.

Consideration was then given to more prolonged storage of the vitrified material. Maintenance at −196° C. for any lengthy period was clearly impracticable with the apparatus available. The results given in the Table, however, do not suggest that when 1-mm. tubes are used there is any advantage in vitrifying at −196° C. as compared with −79° C. An experiment extended this conclusion for larger containers, and further showed that transference from −196° C. to −79° C.

had no adverse effect. Ampoules containing 1 c.cm. of semen were therefore vitrified at −196° C. or −79° C. and maintained at the latter temperature for 2 days and 8 days. In each case thawing out showed that an abundance of spermatozoa had survived. A long-term experiment has now been set up, but in view of the work of Jahnel and of Shettles it is fairly certain that under optimum conditions large numbers of human spermatozoa will survive prolonged vitrification.

A much more important and doubtful point is whether vitrification affects the power of the spermatozoon to fertilize and activate the egg and induce normal embryonic development. In the experiments on fowl spermatozoa, quoted above, normal development was not induced after freezing for 1 hour at −79° C., but the partial dehydration before vitrification may have affected their genetic properties. The question is of great interest. Artificial insemination of humans will no doubt become increasingly common, and the elaboration of a method permitting of prolonged storage and transport of the semen without affecting the genetic properties of the spermatozoa would open up remarkable possibilities. It is not obvious how the problem of genetic modification is to be investigated with human material, and it is unfortunate that the spermatozoa of laboratory mammals, including those of the Rhesus monkey, are killed by vitrification under any conditions so far investigated.

Summary

A large proportion of human spermatozoa survive for long periods in semen frozen in bulk at −196° C. or −79°C.

Spermatozoa do not survive when minute amounts of semen are frozen as films or in fine capillary tubes.

The rate of freezing and thawing is not the primary factor in the survival of human spermatozoa exposed to low temperatures.

I am much indebted to Dr. P. M. F. Bishop, Guy's Hospital, for making arrangements with the donors.

HAEMOLYTIC STREPTOCOCCAL THROAT INFECTIONS: THEIR COMPLICATIONS AND SEQUELS

WITH SPECIAL REFERENCE TO PENICILLIN TREATMENT

BY

P. ROBINSON, M.D.

The British garrison in a small Italian harbour town has recently had a very high incidence of carriers of haemolytic streptococci. No systematic survey had been attempted, but a throat swab from any unselected person not showing in the culture at least a few colonies of haemolytic streptococci was an unusual occurrence. Accordingly the number of admissions for haemolytic streptococcal tonsillitis was considerable—79 cases, including 11 peritonsillar abscesses, in 6 months. A few complications such as pneumonia and scarlet fever also occurred. Along with the streptococcal infection ran a high incidence of erythema nodosum and acute rheumatism—some of the cases developing under our very eyes.

The material may be divided in two groups: the first covers the period Nov., 1944, to Jan., 1945, and comprises 34 cases of tonsillitis, including two peritonsillar abscesses, 3 cases of pneumonia, 1 of scarlet fever, 4 of erythema nodosum, and 6 of acute rheumatism; the second group of patients, treated in Feb.–April, 1945, consists of 43 cases of tonsillitis—including 9 peritonsillar abscesses, 7 cases of erythema nodosum, and 11 cases of acute rheumatism.

Acute Tonsillitis

No special attention at first had been paid to the mild cases. If the temperature did not rise above 102° for more than two days no treatment was given. The throat swabs remained positive in almost every case. An attempt to sterilize the throats in a number of cases through frequent spraying with sulphathiazole powder or calcium penicillin powder failed completely. Cases with pyrexia in the first group were given 20 to 30 g. of sulphathiazole, but the results were no better. Six of the 32 cases returned with a recurrence of their symptoms.

Encouraged by the favourable results achieved by MacGregor and Long (1944) with penicillin pastilles, we introduced them as a routine treatment at the end of January. In preparing the pastilles we followed the technique described by these authors, and gave 10 pastilles daily, 1½-hourly, until the throat became clear. A throat swab was taken on admission, and treatment started at once. Anything between 18 and 46 pastilles was given. On completion of treatment a throat swab was taken again, and the patient was discharged from hospital if it was sterile. No recurrence of symptoms and no complications occurred in this group. The clinical and bacteriological results are summarized in Table I.

Table I.—*Haemolytic Streptococcal Tonsillitis*

	Mild Cases (Temperature not above 102° for more than Two Days)				Moderate and Severe Cases (Temperature above 102° for Two or More Days)			
	No Treatment	Sulphathiazole Spray 4-hourly	Calcium Penicillin Spray 4-hourly	Penicillin Pastilles	Sulphathiazole 20–30 g.	Sulphathiazole 20–30 g. and Calc. Penicillin Spray	Sulphathiazole 20–30 g. and Penicillin Pastilles	Penicillin Pastilles only
No. of cases ..	6	6	6	18	7	7	8	8
Clinical cure in days	4–11	5–10	6–11	3–5	5–21	6–22	3–7	2–9
Average	(7)	(6)	(8)	(3½)	(14)	(13)	(5)	(6)
Days in hospital ..	7–14	7–16	8–14	5–10	8–33	8–30	5–10	4–14
Average	(10)	(11)	(11)	(18)	(17)	(16)	(8)	(8)
No. of patients with positive cultures before discharge ..	5	6	5	0	5	7	0	1

No claim of a permanent sterilization can be made. In two cases of chronic tonsillitis throat swabs remained positive after 88 and 126 pastilles.

Peritonsillar Abscesses

The two patients with peritonsillar abscesses in the first group were given 30 g. of sulphathiazole and inhalations. One recovered in 12 days, but his general condition did not allow discharge from hospital until the 28th day. Repeated throat swabs showed pure growths of haemolytic streptococci. The second was very seriously ill for 3 days and a tracheotomy was considered; he recovered slowly, and left hospital after 26 days. The throat swab before discharge still showed a good growth of haemolytic streptococci.

The results in the nine cases of the second group are summarized in Table II.

Table II.—*Cases of Haemolytic Streptococcal Peritonsillar Abscesses Treated with Penicillin Pastilles*

Patient No.	No. of Penicillin Pastilles Given	Subjective Relief (Days)	Clinical Cure (Days)	Discharge from Hospital After (Days)	Throat Swab on Discharge
1	22	1	3	8	Sterile
2	18	1	2	8	,,
3	40	2	4	9	,,
4	28	2	3	10	A few colonies of haemolytic streptococci
5	32	1	3	8	Sterile
6	36	1	4	7	,,
7	20	1	2	6	,,
8	38	2	4	11	,,
9	42	1	4	9	,,

Erythema Nodosum

The four cases of erythema nodosum in the first group occurred in Jan., 1945, all in patients with mild haemolytic streptococcal tonsillitis—two untreated and two treated with sulphathiazole spray. In one of each group acute rheumatism followed. The rash faded after 8 to 11 days, during which period throat swabs constantly showed a growth of haemolytic streptococci. The erythrocyte sedimentation rate was, and remained, high in the two cases followed by acute rheumatism; and became gradually normal within three weeks in the other two. Five more cases of untreated haemolytic streptococcal tonsillitis developed erythema nodosum at the end of Jan., 1945, when treatment with penicillin pastilles was introduced; they had been given the pastilles as soon as the rash became evident. Two more cases were admitted with a history of erythema nodosum of 1 to 2 days' duration; they also were given penicillin pastilles. In one of them acute rheumatism followed very soon. In all those instances in which penicillin pastilles were given the rash faded and disappeared in 1 to 3 days, and the erythrocyte sedimentation rate dropped from values ranging between 23 and 54 mm. per hour to less than 10 mm. per hour on the fifth day at the latest, with the exception of the one followed by rheumatic fever. All throat swabs became negative within 4 days. All the 11 cases of erythema nodosum had a thorough clinical and radiological examination to exclude tuberculosis.

On two occasions "erythema nodosum" appeared in patients with lobar pneumonia under sulphathiazole treatment. The E.S.R. was 10 and 14 mm. per hour. Sulphathiazole was discontinued, and the rash disappeared within 24 hours. Not a single patient suffering from haemolytic streptococcal tonsillitis and treated with penicillin pastilles developed erythema nodosum.

Acute Rheumatism

Six of our tonsillitis cases of the first group developed rheumatic fever while in hospital; two of them—as mentioned—have also had erythema nodosum. None of the patients treated with penicillin pastilles showed any signs of acute rheumatism. From those admitted with already evident symptoms, 6 were fresh cases and 4 relapses. All but one gave a history of recent tonsillitis, and all throat swabs showed a growth of haemolytic streptococci.

The first six patients were treated with intramuscular penicillin injections. In all but one case pyrexia did not last for more than two days, and the E.S.R. returned to normal at the 14th day at the latest. The swelling remained confined to the primarily affected joints, and subsided in 3 to 10 days. Only one had a clinical course which, though mild, could not be regarded as affected by treatment. Of the patients who were admitted with already developed rheumatic symptoms, 3 fresh and 2 relapsing cases were given penicillin treatment; the rest had the customary doses of sodium salicylate. Two of the primary and one of the relapsing penicillin-treated cases showed the course described above. All the others presented the well-known clinical picture of this disease.

The maximum amount of penicillin given was half a million units. It is noteworthy that three of those patients whose course of illness seemed to have been affected by the penicillin treatment liked the tiresome three-hourly injections immensely and begged us not to discontinue them.

Comment

The superiority of penicillin to sulphonamides in treatment of haemolytic streptococcal infections had been sufficiently stressed by the American National Research Council (1943) and Herrel (1944). The results achieved by Plummer *et al.* (1945) in throat infections with systemic penicillin treatment are better than ours—"Improvement in 8 to 12 hours, fever normal in 24 hours, and all throat swabs negative in 48 hours"—but relapses and complications were frequent unless the treatment was carried through for six days. MacGregor and Long (1944) had good results with penicillin pastilles, but found the treatment of carriers disappointing. The longer duration of illness in our patients as compared with those of Plummer *et al.* may be considered partly counterbalanced by the absence of recurrences and complications and the cheapness and simplicity of the treatment. Our results with peritonsillar abscesses can safely be described as striking; on several occasions the abscesses "melted away."

The relatively frequent occurrence of erythema nodosum is of some theoretical interest. Though there is a tendency to minimize the importance of the "rheumatic" origin as compared with the tuberculous, experimental work has shown that streptococcal nucleoprotein can cause the typical eruptions (Collis, 1932; Coburn and Moore, 1936). Lymphopathia venerea and sulphonamides may also cause "erythema nodo sum." It seems feasible that just as discontinuation of sulphonamides is followed by disappearance of the eruption, s sterilization of the throat with penicillin pastilles may abo or even prevent the development of erythema nodosum.

Though acute rheumatism may follow different infection (Copeman, 1944), the connexion with haemolytic streptococc is certainly common, as shown only lately for the Canadia Army (Feasby, 1944). We are unable to explain by coincidenc alone the benign course of several of our cases treated wit penicillin. This is in contradiction to the conclusions c Watson *et al.* (1944), Herrel and Kennedy (1944), and Foste *et al.* (1944); the last-named author believes even in a deleter ous effect of penicillin. The number of cases reported by thes authors seems to us too small for a definite conclusion.

Summary

Acute haemolytic streptococcal tonsillitis and peritonsillar absce respond well to treatment with penicillin pastilles.

Erythema nodosum following haemolytic streptococcal tonsillit may be aborted, and possibly prevented, by penicillin pastilles.

Some cases of rheumatic fever seem to respond to system penicillin treatment.

I wish to thank Lieut.-Col. J. Pyle, C.O. of the hospital, for pe mission to publish this paper; and Sister K. Keogh, Q.A.I.M.N.S for her valuable assistance in observation and treatment of tl patients.

TWO UNUSUAL STRESS FRACTURES

BY

IAN D. KITCHIN, F.R.C.S.Ed.

AND

DAVID A. RICHMOND, F.R.C.S.

Surgeon, E.M.S.

Stress fracture, as represented by spontaneous fracture of metatarsal, usually the second, was common enough duri the war of 1914–18, but stress fractures of other bones we not recognized as such at that time, and very little was hea on the subject until Roberts and Vogt, in 1939, published cases of "pseudo-fracture of the tibia." Since then stress fra ture—to use the most popular name—has been recognized a variety of sites. That it is a true spontaneous fracture a not a "pseudo" was first demonstrated in one of Hartle (1942) cases, although fracture with displacement did occur one case of Roberts and Vogt's, but there trauma could r be altogether excluded. Now stress fractures have been ported as occurring in metatarsals, fibula, tibia, femur—sh and neck—pubis, vertebrae, and first rib.

In two of the early series of cases published, where the bo involved was the tibia, the average age of the patients w just over 10 years. In all series those affected are alm entirely adolescent or in the early twenties and involved strenuous exertion; though in 1940 Jackson Burrows report a case of spontaneous fracture of the lower third of the fib in a lady of 61 years who had been leading an energetic li It is this almost invariable history of early age and strenu exertion in cases of stress fracture which has prompted us describe in detail the following two cases.

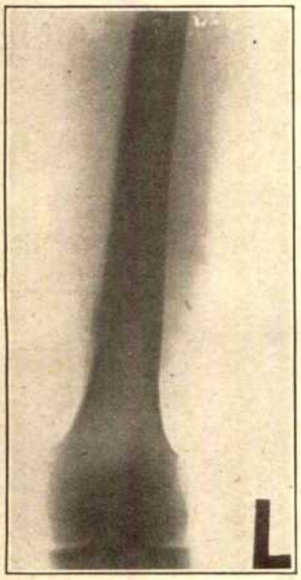
Case I

Miss C., aged 64, housekeeper. She was first seen by one of on Oct. 6, 1944, when she complained of pain in the upper th of the right tibia of one month's duration. There was no hist of injury; her work was not hard and her duties had not va for a number of years. The pain was described as gnawing character, and, strangely enough, was most severe at night, be sufficiently so to keep her awake. On Sept. 27 she had been radiographed at the request of her own doctor, but no lesion was found. Clinically the only positive finding was slight thickening and pitting at the site of pain, and marked osteo-arthritic grating of both knees. *X*-ray examination at this stage showed the early stages of what later proved to be a typical stress fracture. Films taken at intervals revealed all the features of stress fracture, both in its incipient stage and in its progress. The nick in the cortex followed by a clear infraction, with later the typical transverse zone almost right across the shaft, was clearly demonstrated.

The second case is most interesting from the point of view of differential diagnosis, for at one stage the *x*-ray films were so suggestive of sarcoma that a biopsy was performed.

Case II

Pte. T., aged 18. After a strenuous infantry exercise the patient complained of pain in the left knee. There was no history of injury. The pain had been present for some weeks before he was sent to hospital. When seen there it was referred to the knee-joint generally, but more especially to the medial side of the lower end of the femur, where a tender bony-hard swelling could be felt. Full range of knee movement was present. Radiologically (Fig. 1) the swelling was seen to be due to a heaping up of poorly calcified bone in a low broad-based pyramid, and extending along the femoral shaft in both directions from its base was a thin layer of similar new bone. This layer was seen on the medial, anterior, and posterior surfaces, extending practically to mid-shaft. Underlying the pyramid was a region of endosteal new bone extending nearly halfway across the shaft. A cortical nick could be clearly seen in the negative. A tentative diagnosis of stress fracture was made at this stage. The onion-skin layering of the new bone extending along the shaft, however, gave rise to some anxiety. Control films of the opposite femur failed to show any similar changes. The Wassermann reaction was negative, and at no time was there any sign of local inflammation. Ewing's tumour and osteogenic sarcoma were considered, but it was decided to watch the progress of the swelling and take frequent control radiographs.



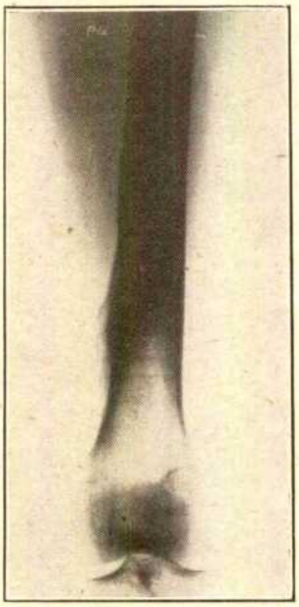


FIG. 1.—Case II. The broad-based pyramid is clearly seen and layering of the periosteum can be made out.
FIG. 2.—Case II. The layering is more clearly seen.

With rest in bed the tenderness and pain diminished, and at the end of three weeks the swelling had not increased in size. Films at this stage showed that the new bone was more densely calcified and better defined. At the end of another three weeks the clinical condition was unchanged, and a radiograph (Fig. 2) showed a further increase in density of the new bone mass, and its outline was smoother.

We now felt that the diminution of pain and tenderness, taken in conjunction with the radiological findings, indicated a healing lesion and almost confirmed our earlier diagnosis of stress fracture; but we were still uneasy about the earlier periosteal changes, and so a biopsy was performed. When the swelling was exposed (D. A. R.)—and this was done easily, there being no infiltration of the surrounding tissues—the pyramid was found to be hard, smooth, and rounded, and it easily scaled off the underlying bone, leaving a smooth normal-looking cortex. A portion of the cortex and underlying cancellous bone was removed. Macroscopically this could not be distinguished from normal bone.

The specimens were examined microscopically by Dr. J. Carr Brundret, who reported the presence of subacute and chronic osteitis compatible with the clinical diagnosis of stress fracture. There was no evidence of Ewing's tumour or sarcoma.

Still later films showed a more calcified new bone which was gradually merging into the normal cortex, and four months after the onset of symptoms the man was discharged to his unit.

Comment

Of these two cases the second is the more unusual, and both clinically and radiologically the more important. The first presents four unusual features—the relatively advanced age of the patient, the nocturnal pain, the absence of a history of strenuous exertion, and the presence of well-established osteo-arthritis; but, apart from that, the behaviour of the case was that of a typical stress fracture, and the diagnosis was never in doubt. Diagnosis was much more difficult in the second case, for while the changes seen radiologically to be taking place within the cortex were those usually associated with stress fractures, the much more widespread subperiosteal changes were very suggestive of sarcoma.

We wish to thank Dr. R. Fawcitt and Dr. J. Blair Hartley for their criticism and help with the films.

TUBERCULIN TESTING IN CHILDREN

A COMPARISON OF METHODS

BY

DOYNE BELL, D.M.
Honorary Physician to the Belgrave Hospital

AND

URSULA JERRAM, M.R.C.S., L.R.C.P.
Senior Resident House Officer to the Hospital

The investigation here reported has been carried out with a view to comparing the sensitivity of children to three forms of the tuberculin skin test: first, the Mantoux intradermal test; second, the Vollmer patch test; third, the diagnostic tuberculin jelly test.

In all, 380 children were tested, of whom 200 did not react to any of the tests. It is with the remaining 180 children that we are concerned. These 180 are made up of two groups of children: first, cases in a sanatorium, diagnosed on clinical, radiological, or bacteriological grounds as cases of active tuberculosis, the lesions being pulmonary, glandular, or in the bones or joints; second, cases attending a children's hospital that were found to be suffering from unexplained cough or glandular enlargement or showed other signs or symptoms giving rise to a suspicion of tuberculosis, or children who gave a history of contact with open tuberculosis.

Technique.—The Mantoux test was performed by the injection of 0.1 c.cm. of 1/10,000 old tuberculin into the skin on the flexor aspect of the forearm, and was read 48 hours after injection. Where this reaction was negative the test was immediately repeated, using 1/1,000 old tuberculin and reading again after 48 hours. The Vollmer patch and the jelly tests were both applied on the back between the shoulder-blades after the skin had been cleaned with aether meth. The jelly was applied in the shape of the letter V, each arm of the V about 1/2 in. long. The jelly was immediately covered by a large patch of elastoplast, about 3 in. by 2 in., extending well beyond the area of skin covered by the jelly; in this way any skin reactions to the elastoplast could be distinguished from reactions to the jelly; in fact, no such reactions were encountered.

The patches used in all the cases here recorded were fresh and from one source. Both patch and jelly tests were read after 48 hours.

Interpretation of Tests.—A positive Vollmer patch test was recorded if the reaction was positive either to human or to bovine tuberculin, or to both. A positive Mantoux was recorded if, after 48 hours, there was a palpable wheal not less than 3/4 cm. in diameter with an area of surrounding erythema. A positive jelly test was recorded where either limb of the V showed wheal formation with surrounding erythema.

Results

The results of the tests on these 180 children are set out in the tables below.

TABLE I.—*Sanatorium Series*

Mantoux Tub. 1/10,000	Vollmer Patch	Tub. Jelly	No.
+	−	−	3
−	−	+	0
+	+	+	31
+	−	+	24

+	−	−	20
−	+	+	0
−	+	−	0
−	−	+	0
21	0	1 (4.8%)	21

* The same case.

These figures show that the chance that the results shown in Table III could have been obtained by random sampling of the same population (the same, that is to say, in the degree of correspondence between positive Mantoux tests and positive jelly tests) as that from which those in Table II were drawn is so low as to be negligible. In fact, the cases in Table III were all those which, by not reacting to the Mantoux at 1/10,000, failed to qualify for inclusion in Table II. One child, who is recorded as reacting only to the jelly test in Table II, reappears as a reactor to the Mantoux at 1/1,000 in Table III.

In respect of frequency of positive jelly tests among the positive reactors to Mantoux 1/10,000, the hospital series (Table II) gives a significantly lower figure than the sanatorium series (Table I)—47% as contrasted with 94.8%.

Now, the hospital series as a whole (Tables II and III) might be considered as a mixture of subjects with *developing* tuberculin sensitivity, whereas the sanatorium subjects (Table I) were, by selection, a sample of *developed* tuberculin sensitivity. It is therefore possible that the sensitivity of the subjects recorded in Table I was, on the average, greater than that of the subjects recorded in Table II. On this view the difference in frequency of positive jelly tests in Tables I and II would be interpreted as meaning that a high degree of correspondence between the two tests could be expected only in subjects who showed a positive reaction to the Mantoux test at a considerably higher dilution than 1/10,000.

Discussion

In a communication by Donald Paterson (*Journal*, April 15, 1944, p. 531) an account was given of the testing by Vollmer patch, Mantoux test, and tuberculin jelly of 100 selected children, of whom 32, 35, and 35 were found to be positive reactors to these tests respectively. It was not stated whether the 35 subjects who gave positive jelly reactions were the same as the 35 who gave positive Mantoux reactions, or whether they included the 32 giving positive patch tests, but this is to be inferred from the conclusion that "it would appear that in this series tuberculin jelly was a more accurate method of performing the skin test than the Vollmer patch." With this conclusion the results here presented are in agreement. But Paterson does not state explicitly what strength of old tuberculin was used in the Mantoux tests which he records. Writing of the reaction of the tuberculin jelly, he states that "experience has shown that . . . the reaction is equivalent to that of 0.1 c.cm. 1/100 old tuberculin (intracutaneous Mantoux test)." In the series here recorded we have not used intracutaneous old tuberculin in greater doses than 0.1 c.cm. of 1/1,000, but a comparison of the two tables showing Mantoux tests at 1/10,000 and 1/1,000 would suggest that a series of children who reacted only to 0.1 c.cm. of 1/100 would give a still lower figure of correspondence between the jelly and the Mantoux tests.

Clinical Notes.—Though it is no part of the purpose of this communication to discuss the significance of these reactions to tuberculin, certain points of interest relating to the clinical condition of these children may be noted. As has been said, the positive reactors in the sanatorium series were children who had all been diagnosed as cases of active tuberculosis. Among the children given us to test six were found who did not react to any form of tuberculin. Subsequent reference to the notes on these cases showed that on clinical and radiological grounds they had already been diagnosed as suffering from "non-tuberculous lesions." In the hospital series of 122 positive reactors 24 were diagnosed as cases of active tuberculosis. In 8 of these cases the tubercle bacillus was recovered by gastric lavage; the others showed either typical radiological appearances or pyrexia, loss of weight, chronic cough, enlarged glands of neck, inflamed joint, or gave a history of contact with open tuberculosis. In this hospital series were three cases of miliary tuberculosis with meningitis, confirmed at necropsy. It is interesting to note that all three gave a positive reaction to the Mantoux test at 1/10,000. Only one gave a positive reaction to jelly and none gave a positive patch test. It may be noted that all these 24 cases diagnosed on clinical and radiological grounds as suffering from active tuberculosis reacted to the Mantoux 1/10,000, and in this sense are comparable with the children in the sanatorium series.

Summary

As compared with the Mantoux test, the Vollmer patches used in this investigation appear to be unreliable to the point of being valueless.

The reaction to the diagnostic tuberculin jelly varies markedly in the two series: in the hospital series 47% of positive reactors to 1/10,000 Mantoux reacted to jelly, whereas in the sanatorium series 94.8% reacted. Of the 21 cases that reacted to the Mantoux test only when performed with 1/1,000, one gave a positive reaction to the jelly, and none to the Vollmer patch test. It seems clear that the jelly is a less sensitive test than the Mantoux in the dilutions used here, and is found to be positive only in those cases with a relatively high degree of allergy to tuberculin.

We wish to thank Dr. W. A. Bullough, county medical officer, school medical officer, and chief tuberculosis officer, Essex County Council, and Dr. M. C. Wilkinson, medical superintendent of Black Notley Sanatorium, for allowing us to apply these tests to their patients; and Dr. R. B. Fisher for advice on the statistical aspects of the results.

The annual report of the Professional Classes Aid Council for 1944–5 was presented by the president, Viscount Hailsham, at the annual general meeting held on July 5. The Council was founded in 1914 to meet the needs of professional men and women among whom the outbreak of the last war had caused distress. It was reconstituted in 1921 because of the need for a comprehensive and permanent system of relief for members of the professional classes and their dependants who had suffered seriously from that war and post-war conditions. It is composed of representatives of most of the benevolent funds of the professional associations, and its work is carried on in close co-operation with them. Lord Moran, P.R.C.P., succeeds Lord Dawson of Penn as Patron for the medical profession, and the British Medical Association and the Royal Medical Benevolent Fund are represented by Dr. Henry Robinson and Dr. W. P. S. Branson. The present war has put a heavy strain upon the funds of the Council, with the result that there has been a mounting deficit at the end of each year. The office is at 20, Campden Hill Square, London, W.8.

POST-OPERATIVE VOMITING IN RELATION TO ANAESTHETIC TIME

BY

J. MORLAND SMITH, D.A.

Anaesthetist to Ministry of Pensions Hospital, Stoke Mandeville

General anaesthesia is a temporary pathological state, but with the improvements in methods of administration of the last few decades there is a tendency for light general anaesthesia to be regarded as harmless. On the whole it may be true that no lasting harm accrues from prolonged anaesthesia, but it would appear, from observations made over a period of 18 months on the incidence of post-operative vomiting, that the duration of anaesthesia is a definite factor in the amount of constitutional upset and post-operative discomfort in the patient.

Adult Cases

The cases from which these figures have been drawn were largely (90%) patients undergoing plastic surgical procedures, mostly in the head and neck regions and requiring endotracheal anaesthesia. In a large number operations were performed in and around the mouth and nose, and a few of these patients inevitably swallowed small quantities of blood post-operatively. All the cases in this series had premedication by omnopon gr. 1/3 and scopolamine gr. 1/150 about an hour before operation. Atropine gr. 1/100 was substituted for scopolamine in patients over 50 years of age, and in occasional cases the dose of omnopon and scopolamine was reduced on account of debility or low body weight.

Anaesthesia was induced in every case by pentothal sodium and maintained by nitrous oxide and oxygen. If 75 to 80% nitrous oxide proved insufficient to maintain adequate anaesthesia, supplementary pentothal, ether, or cyclopropane was employed. A 2% amethocaine jelly was used as lubricant for the endotracheal tubes. Anaesthesia was confined to the first plane except in a few instances where bone or cartilage grafts were taken from the ilium or costal margin. Neither of these procedures, however, requires the depth of anaesthesia needed for relaxation in even a lower laparotomy.

No attempt was made to distinguish between degrees of vomiting, nor was nausea taken into account, conclusions being based on the presence or absence of actual vomiting. In some cases observations were complicated by sulphonamide therapy, and in these any vomiting which occurred later than 12 hours after operation was disregarded.

Duration of operation is divided, as conveniently set out in the perforated anaesthetic record cards introduced by Nosworthy (1943), into four classes: (1) less than 1/2 hour; (2) less than one hour; (3) less than two hours; (4) longer periods. Total cases showed a progressive rise in the incidence of vomiting with the duration of anaesthesia (Table I):

TABLE I.—*Time in Hours*

	Under 1/2	Under 1	Under 2	Over 2
Total cases ..	151	349	459	104
Vomited ..	41 (27%)	98 (28%)	199 (43%)	55 (53%)

Divided into sex groups (Table II) the incidence shows an even more marked progressive increase with the duration of anaesthesia; this table also demonstrates a considerable predominance of vomiting among women, as reported by Davies (1941).

TABLE II.—*Sex Incidence*

Hours:	Under 1/2		Under 1		Under 2		Over 2	
	Men	Women	Men	Women	Men	Women	Men	Women
Total cases ..	67	84	229	120	277	182	69	35
Vomited	8	33	34	64	84	115	22	33
„ Men ..	12%	—	15%	—	30%	—	32%	—
„ Women ..	—	38%	—	53%	—	63%	—	94%

In many cases no supplement to the nitrous oxide was required for maintenance; in the others so small a quantity of the additional agent was used that one would expect very little alteration in the figures for the different supplementary agents (Table III). This does not appear to be the case, but the totals on which the percentages are based are perhaps too small to offer satisfactory evidence. They suggest, however, that both ether and, to a lesser extent, cyclopropane increase the incidence of vomiting. The variation with duration is still largely upheld.

TABLE III.—*Vomiting with Use of Supplementary Agents*

Hours:	Under 1/2		Under 1		Under 2		Over 2	
	Men	Women	Men	Women	Men	Women	Men	Women
Pentothal, nitrous oxide, oxygen								
Total cases ..	43	41	116	67	138	76	26	12
Vomited	6	11	15	30	31	45	8	11
„ Men ..	14%	—	14%	—	22%	—	31%	—
„ Women ..	—	27%	—	45%	—	59%	—	92%
Pentothal, nitrous oxide, oxygen, cyclopropane								
Total cases ..	5	6	33	16	46	27	17	20
Vomited	1	3	6	10	12	18	2	19
„ Men ..	20%	—	18%	—	26%	—	12%	—
„ Women ..	—	50%	—	62%	—	67%	—	95%
Pentothal, nitrous oxide, oxygen, ether								
Total cases ..	19	37	80	37	93	79	26	20
Vomited	1	19	13	24	41	52	12	19
„ Men ..	5%	—	15%	—	44%	—	46%	—
„ Women ..	—	51%	—	65%	—	66%	—	95%

It might be argued that the increase in vomiting with increase in duration of anaesthesia is due to the production of slight degrees of anoxia by surgical shock. This may very well be true; but, generally speaking, plastic operative procedures rarely cause any demonstrable degree of shock unless associated with considerable haemorrhage. Care was taken at all times to avoid anoxia, and an adjuvant agent was added or increased in preference to "pushing" the nitrous oxide. Where any factor predisposing to anoxia was suspected the oxygen percentage was increased considerably, and in certain cases, which do not appear in this series, nitrous oxide was omitted altogether.

Child Cases

A most striking contrast to the above is provided by a separate series of 230 endotracheal anaesthesias in children under 10 years of age. The operative procedures, in these cases also, required the lightest of anaesthesia. Premedication consisted of atropine, and children over 2 years of age were given oral seconal or rectal pentothal for basal narcosis. Anaesthesia was maintained with nitrous oxide, oxygen, and minimal ether, delivered to a short side-feed catheter-mount to which was connected a length of corrugated tubing, thus employing Ayres's "T"-tube principle. Vinesthene or cyclopropane was used in most cases to achieve a smooth and rapid induction to a depth desirable for intubation. A high proportion of these patients vomited in the theatre immediately on withdrawal of the anaesthetic, but the figures (Table IV) are based on whether they vomited or not after return to the ward.

Judged on the numbers available, the incidence of vomiting in children does not appear to be significantly altered by the duration of anaesthesia within the range of the periods studied.

TABLE IV.—*Vomiting in Children*

Hours:	Under 1/2	Under 1	Under 2	Over 2
Total cases ..	10	61	143	20
Vomited . ..	2 (20%)	22 (36%)	35 (25%)	6 (30%)

These observations immediately suggest a psychological factor in adult vomiting, but it is difficult to conceive how this can be correlated with the duration of operation. The patient cannot know, unless told, how long the operation lasted, and in plastic surgery cases the amount of after-pain would be a most deceptive guide to the length of anaesthesia.

Summary

A series of over 1,000 cases is examined, and evidence is presented which strongly suggests that the incidence of vomiting after light anaesthesia is materially affected by the duration of anaesthesia in adults, but that this does not appear to be true in children.

I should like to express my thanks to the Director-General of the Ministry of Pensions for allowing this publication; and to Prof. Kilner, Director of the Plastic Surgery Unit, for continual encouragement and advice.

Medical Memoranda

A Case of Blast Injury

An account of this case is placed on record because of its complex clinical character and its significance in relation to other similar cases which may arise.

Blast injuries have been extensively recognized since the Spanish War, and are due to exposure of the effects of big explosions at close range. The clinical findings are well known and require no recapitulation. A more recently recognized type is that met with in sailors who, while in the water, receive the effect of depth charges. Here the lesions are multiple abdominal injuries varying in severity from subserous haemorrhage to rupture of the bowel. The injuries are associated with severe shock and may present the classical signs of a perforated abdominal viscus. The mortality in cases subjected to surgical treatment is exceedingly high, but this in part may be due to the relatively primitive conditions under which after-treatment must be carried out immediately after a naval action. Similar injuries may be met with during landing operations.

The following report of a blast injury presents several very unusual features—in particular a neurological complication which may be the first of its type recorded.

Case Record

The patient was close to a Japanese grenade when it exploded, and he received part of the force of it. He was picked up unconscious, in which condition he remained for about an hour afterwards. On admission to an M.D.S. he was conscious though drowsy. There were several small wounds on the left arm and leg and the left side of the chest, none of which appeared to be in any way serious. They were in fact the "peppered" small lesions very commonly seen. There was in addition a very profound degree of shock, which did not respond to vigorous treatment to any perceptible degree. This was in no manner accounted for by the visible lesions. Nine hours after injury twitching of the shoulder and neck muscles began. It was severe and persistent, but did not spread. Apart from one vomit described as projectile, no new features developed. When seen 24 hours after injury the patient was still profoundly shocked and not complaining of pain in any part of the body. Examination of the nervous system showed no abnormal signs so far as could be ascertained, except the presence of epileptiform attacks of a Jacksonian type. Lumbar puncture gave absolutely clear fluid at 150 mm. pressure.

The immediate problem was to combat shock and stop the epilepsy. Barbiturates very largely achieved the latter, but the former remained, and death occurred about 72 hours after injury. It may be noted that there was no indication for operation on the head, there being no signs of a space-occupying lesion and careful examination of the shaved head revealing no penetrating injury.

The necropsy findings were as follows: *Brain and meninges* :—Careful search revealed no macroscopic abnormality. Attention was paid particularly to the Rolandic area, and neither haemorrhage nor thrombosis could be seen. The C.S.F. was clear and the ventricular system normal. *Abdomen* :—On opening the peritoneum an area of central peritonitis was seen. This was largely walled off by lymph of recent origin. There was a little pus in the central part and some in the right kidney pouch. The cause was sharply localized gangrene of three sections of the terminal loops of the ileum, each about 3 in. long and matted together. There was no perforation of any of this area, but in places all the coats but the mucosa were split. The state of affairs very closely resembled a mesenteric thrombosis, but the vessels were normal. There was no wound on the abdominal wall or any other pathological condition in the abdomen. All other organs were normal, and there was only minimal sepsis around the wound.

Commentary

The diagnosis was obscure from the beginning, and the injury which gave rise to the symptoms did not present a macroscopic lesion at necropsy, while that which was apparent at necropsy and was the immediate cause of death showed no direct signs or symptoms.

When the patient was seen the diagnosis made was multiple grenade injuries and a cerebral blast injury. The profound shock was considered to be the summation of the original shock plus exhaustion caused by the muscular twitching, though on mature consideration these factors did not appear to be sufficient to produce the degree seen, which was remarkable in itself. The further unsuspected abdominal lesion completed the picture. The aetiology of the abdominal injury was undoubtedly blast. The picture is very similar to that seen in naval cases; the affected portions of the gut were in the central part of the abdominal cavity, most exposed to the effects of blast, and there was no penetration of the abdominal or gut wall. The latter feature explains the lack of abdominal symptoms, for peritonitis would develop only as infection penetrated the bowel wall—a fairly gradual process. The fact that no cerebral lesion was demonstrable is not considered to invalidate the diagnosis: the smallest necessary irritative lesion need be no larger than the few Betz cells involved.

The lessons to be learnt from this case are that blast injuries may arise from relatively small explosions, they may be associated with minimal external wounds, and the effects may be multiple. They should be considered when a patient is shocked beyond the degree expected from the superficial injuries, but full and repeated examinations are necessary—an admittedly difficult ideal in battle conditions. This patient was never fit for operative treatment, but similar lesions are by no means beyond the possible scope of the surgeon.

In conclusion a note might be made that a probable abdominal mortar-blast injury was seen by me. Here the patient was very shocked, though with no external injury. Resuscitation was successful, but for four days he had persistent abdominal pain and distension and persistent tachycardia. Recovery took place after four days, during which time he was in a very much poorer condition than the signs appeared to justify.

Poisoning by Accidental Drinking of Trichlorethylene

Although poisoning by trichlorethylene fumes is not uncommon it is rarely that one meets a case in which the accidental drinking of this industrial solvent takes places. Two cases are reported below.

Case I

Mrs. H., housewife, aged 29, had had a cold for a few days. At about 6.45 p.m. on Sept. 25, 1944, a neighbour (Mr. M.) suggested she should take a dose of his medicine (℞ Pot. iodid. gr. 2½, ammon. carb. gr. 2½, chloroform water to 1/2 fl. oz.). She drank about half an ounce.

At 7.20 p.m. I visited Mrs. H. in response to a telephone call. She lay on a couch in a coma. Apparently, immediately she had taken the dose of medicine she spluttered. She complained that the smell of the medicine had "gone to her nose," and she had an acute lacrimation. She was given some water, which she vomited, and sneezed about a dozen times. Her legs had gone weak and she had had to sit down, and there was a hammering in the head. The condition quickly passed into unconsciousness. Just previous to the unconsciousness some whisky had been given to her, but was returned in the vomit.

Physical examination showed her colour to be good, there was shallow breathing, and the pulse was of good volume. The heart sounds appeared normal. The pupils were widely dilated and did not respond to light. The limbs were completely flaccid. Reflexes were equal. At 8.15 p.m. the patient roused a little, vomited, and recognized those around her. The odour of her breath was mainly that of whisky, and she complained of frontal headache. She lapsed into a state of drowsiness again, and remained so on and off all night. She herself subsequently did not remember anything of her rousing, and only at midnight did she realize where she was. Progress continued slowly, the main symptom being a frontal headache, which persisted till Sept. 29. Next day she complained of abdominal pain and heaviness in the right subcostal region. Examination showed that there was slight tenderness over the liver, but no enlargement was discernible. Bowels were open normally and the urine was negative in albumin, sugar, and bile. She recovered completely in 10 days.

Case II

This patient, Mr. M., is a fireclay miner aged 47. At about 6.45 p.m. on Sept. 25, 1944, he took a tablespoonful of his medicine out of the same bottle as he handed to Mrs. H. This left about two doses in the bottle, and he had another "taste," which left the bottle nearly empty. He did not feel any ill effects until about 8.40 p.m., although it was observed, without at the time any particular notice being taken of it, that he stumbled a little when approaching my car at the time Mrs. H. was being visited.

At 8.40 p.m. he complained that he felt drunk, and almost immediately vomited copiously. He was found later by his son some time after 9 p.m. in a dazed, helpless condition, and this was taken to be a bout of alcoholic excess. However, the son on smelling the vomit detected the odour of trichlorethylene. He gave his father salt and water, which produced further vomiting. Mr. M. himself remembered nothing until next morning. He was not seen by me until Sept. 26, when he reported that he still felt "swimmy" in the head and weak in the legs. He had a very dry tongue, but there had been no further sickness. He recovered completely in five days.

Comment

It transpired later that the son of Mr. M. had a 10-oz. bottle, containing trichlorethylene for cleaning purposes, similar to that in which the cough mixture was kept, in the same cupboard, the only difference being that the cough medicine had a label giving the directions for taking it and the trichlorethylene bottle had none. This latter bottle was found to be nearly empty. Both contained at the time of the above events about three or four tablespoonfuls of fluid. It was obvious that Mrs. H. and Mr. M. had between them consumed trichlorethylene in place of the medicine. It is possible that the delayed effect in the case of Mr. M. was related to his accustomed daily consumption of alcohol. He drinks on an average about four pints of beer a day. The bottles, in addition to being of the same size, contained a similar colourless fluid with a similar smell.

Kirkburton, Huddersfield. J. A. STEPHENS, M.R.C.S., L.R.C.P.

A Sporadic Case of Trichiniasis

During the war at least three outbreaks of trichiniasis have been described (Sheldon, 1941; Lee, 1941; Garrod and Maclean, 1941; Davis and Allott, 1941; Bacon, 1941), the cause being traced to eating raw or undercooked sausages. The sporadic case now recorded is interesting in its full clinical and epidemiological features, and also in showing a positive intradermal reaction; for the diagnosis of trichiniasis in man can sometimes be tedious and uncertain, especially in an isolated case.

CASE HISTORY

Mrs. A., aged 36, an evacuee from London, was admitted to hospital on March 9, 1945; the illness started on March 5 as a cold with general aching in the body, and with headache, sweating, and shivering attacks. It was thought to be influenza.

On admission she had pronounced oedema of the face and eyelids, the tongue was furred, the throat clear, but there was generalized tenderness of the muscles. Temperature was 103°, pulse 100, and respiration 24. In the chest and abdomen nothing abnormal was detected, and there was no rigidity of the neck. A scalding and burning sensation was felt on micturition, and menstruation had been irregular. She felt thirsty, but had no appetite, and was very drowsy and mentally confused.

Course of the Illness.—The temperature continued at 100–103° for six days after admission; it then fell by lysis: the oedema of the face and eyelids was severe for three or four days and then gradually cleared. Headache in the occipital and bitemporal regions was marked with buzzing in the head, these symptoms disappearing just before the temperature began to fall; the muscular tenderness also remained for several days. Subungual splinter haemorrhages, often characteristic, were not seen. On March 17 the temperature was normal, there were no symptoms, and appetite was returning; and on March 21 she was discharged to a convalescent home. On March 10 her blood urea was 26 mg. per 100 c.cm. A blood count showed a leucocytosis of 15,000 per c.mm., with eosinophilia of 38%. Urinalysis: Sp. gr. 1018; *p*H 5.0; albumin, trace; sugar or acetone, *nil;* centrifuged deposit, a few leucocytes and an occasional red blood corpuscle; no casts or crystals; culture sterile.

Intradermal Test.—Through the courtesy of the Emergency Public Health Laboratory Service Dr. W. D. H. Stevenson, C.I.E., of the Ministry of Health Government Lymph Establishment, kindly sent two ampoules (0.1 c.cm.) of trichina antigen 1:8000; an intradermal test on March 21 (16th day of illness) was negative. The test was repeated on April 17 (43 days after the illness began), a positive reaction being obtained. Almost immediately after the intradermal injection a wheal came up with definite pseudopodia which looked rather like a small starfish, and within about 10 to 15 minutes a zone of erythema surrounded the wheal; the erythema disappeared after a short time, but the wheal remained for several hours; it was about 10 mm. across. The control showed no reaction.

EPIDEMIOLOGICAL NOTE

Mrs. A. ate sausages twice a week—every Tuesday and Thursday; she herself took them uncooked, spread on bread, while her husband and three children ate them well cooked in the usual way. It appears that her mother was told by a doctor years ago to give her underdone meat because she was delicate, and she says she takes other meat rather underdone. The sausages were bought from a small general store which obtained its supplies from a large firm in the South-West; there had been no other complaints, and it was not possible to incriminate any of the pork or any particular batch of sausages. Thus the incubation period could not be obtained, although it is usually stated to be within 7 to 12 days (Beeson, 1941).

My thanks are due to Dr. G. T. Allerton, honorary physician, Torbay Hospital, for permission to publish these notes; to Dr. J. V. A. Simpson, M.O.H., Torquay, for his help and advice; and to Dr. J. Quinlan for pathological investigations.

Reviews

THE SCIENCE OF NUTRITION

The Science of Nutrition. By Henry C. Sherman, Mitchill Professor of Chemistry, Columbia University. (Pp. 253. 15s.) London: Oxford University Press. 1944.

This book aims at giving a summary and evaluation of the present status of the science of nutrition and its social importance, with the minimum of technical terms and without any demand for a specific training in science on the part of the reader. At the same time it demands curiosity, and is suited to those who appreciate that science is a changing and expanding structure, based on evidence, and does not consist of a series of *ex cathedra* pronouncements such as are common in many elementary books on nutrition. On the whole the book is highly successful. The author stresses how progress depends on carefully controlled experiments and how it moves from qualitative to quantitative knowledge and thence to further advances. Enough history of the discoveries is given to illustrate the nature and the difficulties of this progress.

If the knowledge that has been gained is to be used for assessing and improving human nutrition we need to know the contributions that various foodstuffs make towards meeting the requirements for various nutrients. This is done in a well-balanced account which gives proper recognition to the value of cereals. Having concluded that the main change needed in American diets is to increase the amounts of fruit and milk, the author discusses different methods by which the public can be educated to make these changes and the national nutrition policy involved in making such changes possible.

The one criticism that can be made of the book is that the outlook throughout is that expressed in the last sentence: "The question, What particular thing does such nutritional improvement do? hardly admits of a more specific answer than that it offers us the option of a more liberal term of years of more efficient life with which to do what we will." Abundant evidence is adduced to show that improved nutrition does offer this prospect to rats. But several studies made during recent years have appeared to show that adult human beings are less susceptible to the ill effects of a defective diet than might be expected from animal experiments. It has proved more difficult than was anticipated to demonstrate, in adults, the chronic suboptimal states (as distinguished from the early stages of gross deficiency) that were looked for. Undoubtedly health improves with improvement of the food supply; but in most cases other relevant factors besides food vary with it. Even experimental improvements of the diet of children whose basic diet was not grossly deficient have not had the effects that were hoped for. Doubtless these experiments have been carried out over too short a fraction of human life to show conspicuous results. But the position is difficult, and ambitious promises, made now to peoples in Britain and the U.S.A. as a whole, may lead to disappointment and scepticism later. There remains, however, no doubt that the poorer sections of the population in these countries—and the population of a great part of the world—would benefit enormously if their diet were improved, and it is on this certain improvement that we should concentrate our energies.

DERMATOLOGY AND SYPHILOLOGY

The 1944 Year Book of Dermatology and Syphilology. Edited by Marion B. Sulzberger, M.D. Assistant Editor, Rudolf L. Baer, M.D. (Pp. 544; illustrated. 18s. 6d.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

An atmosphere of bellicosity is not supposed to be favourable to the development of medical science, but the editors of this yearbook are of the opinion that military life and the problems of military medicine have given an unusual stimulus to dermatology. There is no doubt of the importance of dermatology in military medicine, for in certain theatres of war skin diseases account for as many as 74% of all men reporting sick, and sometimes as much as 14% of all military ineffectiveness is found to be due to skin disease. As usual the yearbook finds space to mention all the chief items of dermatological progress and observation which have come to light during the year under review, and the utility of the volume is much enhanced by the "jacket-quiz" printed, as the word implies, on the paper jacket but which would perhaps be better included in the permanent volume. It forms a very searching questionary, and there is no doubt that any dermatologist who can pass the examination paper consisting of the twenty questions included in it may consider himself as extremely well read in the literature of the specialty. The next best thing is for him to study the yearbook with due care.

One of the features of this annual is a special article at the beginning by the editors. This year it is on "scratch tests"—an important method of investigation but very difficult to use with accuracy. This article forms an excellent guide to the subject, which is likely to become of increasing importance. In America it is beginning to be used industrially to test the purity of manufactured articles. For example, in the manufacture of certain paper towels formaldehyde is used. This substance may cause dermatitis. In order to make sure that it has been effectually eliminated from the finished article individuals known to be allergic to it are patch-tested with the towels. Proved free from formaldehyde by this means, this brand of paper towels has been used by millions with impunity over several years.

A very interesting subject well discussed in this volume is the treatment of syphilis by means of penicillin. The editors are of the opinion that this drug is going to revolutionize the therapy of syphilis when the disease is treated in its earlier stages, and that it is of great use in neurosyphilis and congenital syphilis, although they very properly enter a caveat against unrestrained optimism, pointing out that penicillin has not yet been long enough available for the formation of final judgment on its antisyphilitic capabilities.

The 1944 volume of the yearbook is well up to the standard set by its predecessors and should be in every dermatologist's library.

TRAUMA AS A CAUSE OF DISEASE

Trauma in Internal Diseases. With Consideration of Experimental Pathology and Medico-Legal Aspects. By Rudolf A. Stern, M.D. Foreword by Francis Carter Wood, M.D. (Pp. 575. $6.75.) New York: Grune and Stratton.

It falls to the lot of almost every doctor at some time to give legal evidence in a case in which the agency of trauma as a cause of subsequent disease is disputed. Anyone perplexed by this duty will find ample guidance in the work entitled *Trauma in Internal Diseases*, by Rudolf A. Stern of New York, which is based not only on the author's evidently large experience of compensation cases but on a thorough study of the literature: the concluding bibliography contains 2,110 references. Illustrative cases are freely quoted; indeed they occupy more space than the arguments based on them. After a chapter on the general principles by which judgment on traumatic aetiology should be guided, and one on "infectious" diseases, the subject is dealt with regionally; diseases of the circulatory system occupy 164 pages, of the respiratory system 160, and of the alimentary 109. The other principal sections, each rather shorter, are devoted to the kidney, metabolic diseases, the endocrines, and the blood and lymphatic system. Cancer is dismissed briefly, the reader being referred to other extensive reviews of this thorny subject.

To those who have not considered the matter before it will seem astonishing that some of the conditions mentioned—such, for example, as acute yellow atrophy of the liver or Hodgkin's disease—could ever have been supposed to be due to trauma. The author is commended in a preface by Francis Carter Wood for not being dogmatic. He has indeed an open mind, but with a bias in favour of the claimant in the sense that he is reluctant to deny any possibility, however improbable. Merely to base judgment on observation is to place oneself at the mercy of coincidence, and possibly of imperfections in the observation itself. The author accepts published records without question, but among the hundreds which he quotes from all manner of sources there are many about which the sceptic will reserve judgment in the absence of further information. Among the least convincing sections is that dealing with pulmonary tuberculosis, since proof of the non-existence of the disease before injury is plainly impossible. That tooth extraction should not be mentioned as a traumatic cause of subacute bacterial endocarditis is surprising, and the author has old-fashioned ideas about the nature of "surgical" scarlet fever and the source of infection in actinomycosis. He rightly observes that to assess the possible significance of trauma is all the more difficult if the aetiology of the disease itself is unknown: there are 100 recorded cases of supposedly traumatic leukaemia.

Whether the reader regards the deliberate credulity of this book as a fault or not, he will find it an invaluable compendium of information on which to base his own judgment. It is also a textbook of a branch of pathology of great interest, particularly in the more matter-of-fact aspects of its subject, such as the extraordinary nature and diversity of internal injuries which may result from violence without penetration.

SINGING AND BREATHING

The Singing of John Braham. By John Mewburn Levien. (Pp. 40; illustrated. 7s. 6d.) London: Novello and Co.

Mr. J. M. Levien, a distinguished teacher of singing, has written a short account of John Braham (1774–1856), who during the first half of the nineteenth century was the leading tenor singer, in which position he preceded Sims Reeves. He made his first appearance at Covent Garden in 1787, and had become famous already before the end of the eighteenth century. His name is now little known to the public, though for many years he kept the position which he had attained so early, and it is evident that as a singer he was unique and without a serious rival. It is recorded that he possessed a compass of twenty notes, and had such a command of *portamento* that he could pass through the whole range by semitones with great rapidity, each note and the joining thread of tone being perfect, so that no break was perceptible when he passed from tenor to falsetto. It is of interest to remark here that the slow-motion film of the cords made by the Bell Telephone Company for Dr. Pressman shows how different is the mechanism of the shortened cords in the falsetto from the movements in the tenor, the difference being clearly defined by the slowing down on the great scale of 1–250—a belated tribute to the power and capacity of Braham.

Mr. Levien has included in this memoir a chapter by Dr. George Cathcart entitled "A Scientific Justification of the Historic Method of Voice Production." In this Dr. Cathcart extols the Italian method of voice production, and challenges the modern fashion of abdominal breathing. He remains a confirmed and unrepentant advocate of thoracic breathing and the art of *bel canto*. The fact is that great singers breathe as Nature prompts them and are not influenced by any deliberate system of breathing; but the considerations which Dr. Cathcart enumerates have a sound physiological basis, though apparently they are not acceptable to most modern teachers. Braham, at all events, was a conspicuously successful exponent of thoracic breathing. The memoir is embellished by several most pleasing illustrations.

Notes on Books

Virtus Diseases in Man; Animal and Plant, by Gustav Seiffert, is an attempt to give an interim survey of the status of virus investigation covering the major research work done since 1933. It is translated by Marion Lee Taylor, Ph.D., and published at the price of $5.00 by the Philosophical Library, 15, East 40th Street, New York, under the auspices of the National Research Council of the U.S.A. The author's aim was to guide those who need closer acquaintance with the literature on the virus problem. His purpose being to provide an introduction to the subject as well as a key to published reports, a chapter on working methods of investigation has been added. The bibliographical references appear seriatim as footnotes to the pages. which number 332, including a brief index.

The Lady Gowrie Child Centres were planned by the Commonwealth Department of Health in Australia to study the health, growth, and development of groups of pre-school children. In six large cities a uniform programme of investigation was carried out, and although it was to some extent interrupted by the war, it has been possible to collect and analyse much of the routine data on such matters as physical defects, nutritional states, posture, and causes of absenteeism. Dr. F. W. Clements and Miss Margaret Macpherson, of the Australian Institute of Anatomy, are responsible for *The Health Record* issued at Canberra by the Commonwealth Government Printer, and this is a publication of great value for all workers in the field of child health.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 18 1945

FROM WAR TO PEACE

The tremendous happenings of the past week or two call for little commentary in a professional journal whose readers must be full-fed with the news and its implications, both by what they see in the lay newspapers and by what they hear from their radio sets. British medicine has played its part with courage and endurance and has achieved much in many fields of war work. Our profession now shares the general feeling of relief and gratitude, but knows well that the end of hostilities can bring no respite from the task of succouring a torn and distracted world. The months and years ahead call for renewed efforts and for clear thinking by medical men and women, upon whose energy of mind and body the war has levied incessant toll. Hard-pressed as they are, they will rise to this demand in the spirit that has actuated them since 1938. Our profession has suffered many losses in the service of the country, and only a part of these is visible in the official casualty lists. British medicine looks backwards over the seven years with pride for what it has done, and forwards into an unpredictable future with sober determination.

On Nov. 16, 1918, there appeared in these columns, under the heading "The End Crowns All," a leader written on Armistice Day by a master hand. It expressed, in a few words well fitted to the occasion, a number of ideas that were latent in the minds of thoughtful people who had watched that war through medical eyes. It foresaw the heavy tasks that lay ahead but not the ruin of our hopes of lasting peace. Disillusionment came slowly. Within 21 years we were engulfed in another and a far worse "war to end war" which has stretched our profession to the utmost of its powers. Let us pray now in quiet mood that *Finis coronat opus* will prove a truer epitaph this time, and that peace on earth has come to stay for more than a generation. Publicists are saying day by day that if the atomic bomb does not abolish war it will bring civilization down in ashes.

SYRINGES AND SPIRIT

"Supposedly sterile syringes," as they were referred to in an editorial in this *Journal* some years ago, used for the injection of medicaments or immunizing agents, have on many occasions transmitted more or less serious infections. When such disasters occur they are usually attributable to faults in the technique of sterilizing or handling the syringe, and it is well known that methods in common use, although they rarely lead to any serious trouble, are imperfect and involve an element of danger, however slight. There is also much doubt and misconception about the efficacy of different methods of sterilizing syringes. A committee of the Medical Research Council has now produced a memorandum[1] on this subject entitled "The Sterilization, Use, and Care of Syringes." As its title implies, the treatment of the subject is comprehensive: measures to ensure sterility are the principal theme, but there are also sections on the choice of syringes and needles, the care and sharpening of needles, a method of testing syringes for leakage, the organization of a clinic for mass inoculations, and the precautions necessary in employing syringes for certain special purposes, such as tuberculin tests, the withdrawal of blood for antitoxin estimations, and mass intravenous injections.

The first and most emphatic injunction is that syringes used for aspirating septic material or any possibly infected body fluid must never be diverted to an aseptic purpose, such as the injection of a sterile medicament. This is an elementary precaution, the neglect of which caused one of the notorious disasters of recent years. The clue to the efficient use of syringes is to have enough of them, and to have separate ones for these different jobs is the duty of every practitioner. It is then urged that, as there is no known method which can absolutely be depended on to sterilize a syringe except autoclaving or exposure to a temperature of 160° C. in a dry oven, one of these methods should preferably be employed. This is to sound the death-knell of the Record syringe, since the cement at the glass–metal junctions is liable to melt at these temperatures. The memorandum does in fact strongly advocate the universal substitution for the glass–metal syringe of a two-piece all-glass syringe, and refers to a British Standard Specification for such a syringe [B.S. 1263 (1945)] which is now available. The all-glass syringe has another important advantage in being much more easily cleaned; it should have no obscure crevices in which traces of its previous contents may lurk. The ideal policy is undoubtedly to have plenty of such syringes, to encase them in glass tubes, and sterilize them by dry heat. Under the heading of "A Syringe Service for a Hospital" it is advocated that in a large hospital a single department should have the care of all the syringes, cleaning, sterilizing them by this method, and re-issuing them to all wards and other users; it is mentioned that this service has existed in one hospital for some years and worked well. Boiling is given as a second-best alternative; it will not kill sporogenous bacteria unless sodium carbonate is added to the water, "but this practice is not recommended because the resulting alkalinity of the syringe may affect drugs or biological products to be injected." Admittedly the risk of infection by sporogenous bacteria is remote compared with that by pyogenic cocci, but it exists; and both for this reason and because a dry syringe is preferable to a wet one the method is not ideal. The hot-oil method was tested and found to be ineffective.

In order to decide whether any chemical method of sterilizing a syringe is feasible members of the committee found it necessary to supplement existing knowledge by performing *ad hoc* experiments. Their findings are that hypochlorites, phenols, chlorophenols, quaternary ammonium salts, and detergents are "ineffective as disinfectants for syringes, and may damage the material to be injected." The main reason for their inefficacy is evidently that "they cannot be guaranteed to penetrate into the crevices and corners of a syringe in which bacteria may lodge," for the only chemical disinfectant receiving even a qualified recommendation is 70–75% V/V alcohol; and, although this sterilized a two-piece all-glass syringe when it was taken apart, it did not sterilize a glass–metal (Record) syringe under any conditions. It is therefore recommended that the disinfection by spirit should be confined to syringes employed for and by a single patient for the injection of insulin or adrenaline. Many experiments, briefly described in an appendix, were made with spirit, syringes themselves and various other infected test objects being used before this conclusion was reached. This appendix also gives a concise but comprehensive review of what is known about the disinfectant action of alcohol, and of infections caused by injections made with syringes which spirit had failed to sterilize: these include numerous reports, mainly Continental, of cases of gas gangrene. Reference to this appendix should provide the answer to many questions which have been asked about the suitability of spirit for various types of disinfection. The salient points are that alcohol acts best in a concentration of 75% by volume in water, and scarcely at all when undiluted; that it acts only on vegetative bacteria; that it has little power of penetration; and that in general it is a better disinfectant than most for skin but an unreliable one where absolute sterility is necessary, as for instruments.

---

[1] M.R.C. War Memo. No. 15. H.M. Stationery Office, 1945. Price 4d.

Further original observations on the disinfectant action of alcohol were reported in the Aug. 4 issue by G. T. L. Archer, with particular reference to its use on the skin. His findings, with six different methods, conform in general to those of previous workers. One interesting point well brought out here which should not be overlooked is that when the skin is moist—and this applies particularly to use in hot climates—undiluted alcohol is effective, and the concentration used should be not less than 80%, owing to dilution with sweat. Archer also studied the disinfectant action of ether on the skin, and found it ineffective, presumably owing partly to the rapidity of its evaporation. Ether is apparently also more active against bacilli of some species than against cocci. There is perhaps something yet to be learned even about the commonest of all everyday acts of disinfection—that of the normal skin preparatory to an injection.

VACCINATION AGAINST WHOOPING-COUGH

The protective effect of bacterial vaccines is notoriously difficult to assess. There is not one of which we can say with confidence that under such and such conditions it will have a given effect on the morbidity or mortality rate. On the whole it looks as if inoculation was of greater value against diseases, like enteric fever and plague, in which there is an invasion of the body tissues affecting particularly the reticulo-endothelial system, than against those, like dysentery and cholera, in which the organisms remain confined to a mucous surface. If this is true of the intestinal diseases it is still more so of the bacterial infections of the respiratory tract. Several attempts on a big scale to vaccinate against pneumonia and meningococcal infection have proved a failure or have yielded inconclusive results. The single exception for which success has been claimed is whooping-cough, and it is therefore all the more necessary to look with care into the credentials of pertussis vaccine.

The early attempts, from 1915 onwards, to vaccinate against whooping-cough were reported on very favourably. When, however, they were repeated, with the inclusion of a non-vaccinated control group, serious doubt arose as to the value of the method, deepening with further trials into almost complete scepticism. Leslie and Gardner's discovery[1] of the phasic variation of *H. pertussis*, and their insistence on the use of Phase 1 organisms alone for preparing vaccine, provided a plausible explanation for the failure of vaccines that had hitherto been made from old rough strains, and pointed the way to a more hopeful approach in the future. Reports on the success of the new vaccine were not long in forthcoming. Madsen,[2] Sauer,[3] Kendrick,[4] and Bell,[5] among others, each carried out large-scale trials which seemed to show that the attack rate was greatly lowered, and that when the disease was not prevented it was rendered very much milder. With such testimonials behind it, pertussis vaccine was accepted with acclamation and took its place, along with diphtheria prophylactic, in the routine preventive measures employed in clinics and children's institutions. Are we really confident, however, about its value? Have the conditions of the apparently successful trials been above criticism? And is there complete unanimity on the fact, if not on the degree, of protection? These are questions that must be answered before pertussis vaccine, like diphtheria alum-precipitated toxoid, receives the full sanction of the Ministry of Health and is issued free to all. Let us take the last question first. There have been reports, both in this country and in the United States, of complete or almost complete failure to protect against whooping-cough by use of the vaccine. Two of the most striking are those by Doull and his colleagues[6] in Cleveland, Ohio, and by Siegel and Goldberger[7] in New York. Doull, whose observations were made at child health centres, took particular care to avoid the numerous pitfalls that attend trials carried out in a clinic population; and Siegel and Goldberger avoided them almost completely by working in an institution where the children were living under similar conditions and were exposed to similar risks of infection. The same cannot be said of many of the apparently successful trials. The great difficulty in clinic investigation is to secure virtually identical conditions in all important respects of the inoculated and the control groups. Special attention has to be paid to the general intelligence and co-operativeness of the mothers; the housing and social conditions under which the children live; the size of the family; the occurrence of previous cases in the family; the frequency, degree, and time of exposure to the risk of infection; and the care with which the children are followed up. None of the four observers we have mentioned who reported favourably on pertussis vaccine appears to have conformed entirely to the necessary requirements. Sauer never had a proper control group; Madsen says practically nothing about his two groups except that they were unselected and were comparable in respect of age, time of epidemic, and surrounding conditions; Kendrick's groups differed in the average size of the family, in the frequency of exposure to infection, and in previous history of whooping-cough; and Bell's observations on his two groups were apparently not started at the same time. That misleading results may follow neglect of these factors is brought out clearly by the experience of B.C.G. vaccination in New York. When vaccine was given to the infants of mothers who accepted the offer, and the infants of mothers who refused were treated as controls, the results of vaccination were favourable. When, however, the element of selection was eliminated by vaccinating infants in alternate rotation, no difference between the vaccinated and control groups was observed.[8]

The paper on page 205 by Drs. McFarlan, Topley, and Fisher raises once again the issue of pertussis vaccine. In their earlier investigation McFarlan and Topley[9] restricted their observations to children in residential nurseries, where almost perfect equalization between the two groups could be assured. In their present investigation they included a clinic population as well, taking care to avoid so far as possible the errors to which we have just alluded. In neither investigation did they obtain evidence that pertussis vaccine had any effect on the attack rate or on the severity of the disease. What is the explanation of these results? Their first investigation was criticized on the ground that the dose they were using was too small, but a comparative study has since shown that, as the English vaccine contains approximately three times as many organisms as American vaccine of the same labelled strength, this objection cannot be upheld. Another criticism that might be made is the same as that which was levelled against Doull's work—namely, that the vaccine used was prepared from washed organisms, the toxin of which had been removed. It is doubtful how much force there is in this objection. Considering that the toxin of *H. pertussis* is very labile and is apparently absent from Sauer's vaccine; that there appears to be no cross-immunity between whooping-cough due to *H. pertussis* and that due to *H. parapertussis*, which share the same toxin but which differ antigenically; and that the toxin is said by Flosdorf, Bondi, and Dozois[10] to be non-antigenic in human beings—it may well be questioned whether the protective effect of pertussis vaccine can be related to its toxin content. One thing is clear: before steps are taken officially or unofficially to extend the practice of vaccination against whooping-cough further observations must be carried out under the most carefully controlled conditions to determine the value of this procedure. It is comforting to learn that an investigation is at present in progress at Oxford in which Sauer's vaccine, obtained directly from the United States, is being submitted to trial. Unless the results are more favourable than those hitherto obtained with vaccines of British manufacture it will be all the more necessary to pause before countenancing a practice which, when once established, will take many years to abolish.

LYMPHOCYTES AND ANTIBODIES

Some interesting evidence has recently been obtained suggesting that the lymphocyte is intimately concerned in antibody formation. W. E. Ehrich and T. N. Harris[11] showed that when an antigen is injected into the pad of a rabbit's foot antibody appears in the efferent lymphatic draining the popliteal lymph node; this node undergoes marked hyperplasia, increasing five times or more in size, and the lymph from it contains large numbers of lymphocytes. That these cells actually form the antibody seems to have been proved beyond doubt by T. N. Harris, Grimm, E. Mertens, and W. E. Ehrich,[12] using the same elegant and delicate technique. They collected lymph from the efferent lymphatic five to seven days after the injection of foreign red cells or typhoid vaccine into the foot, separated the cells from the plasma, extracted the former by freezing, and compared the antibody content of plasma and cell extract. The result of this difficult proceeding—difficult owing to the very small quantities of material available—was to show that the cells usually contained from four to eight times as much antibody by volume as the plasma. To verify the proposition that these lymphocytes had formed the antibody it had to be shown that they do not absorb it. Lymphocytes containing sheep's cell agglutinin were therefore suspended for 24 hours in plasma containing typhoid agglutinin. When plasma and an extract of the cells were tested later it was found that the cells had given up some of their antibody to the plasma but absorbed none of the different antibody contained in this, nor had the titre of the plasma antibody fallen. In order to clinch this argument by substituting *in vivo* for *in vitro* conditions anti-erythrocyte serum was injected into a popliteal lymph node previously immunized with typhoid bacilli, the efferent lymphatic being ligatured in order to prevent its escape. Five hours later lymph was obtained from it and tested as before; the injected antibody was found in high concentration in the plasma only, the amount in the cell extract being usually much lower, and only such as would be expected from the traces of plasma in the cell deposit from which the extract was made.

That lymphocytes liberate antibodies appears to have been shown by another type of experiment, which incidentally throws light on another phenomenon—the anamnestic reaction. T. F. Dougherty, Jeanne H. Chase, and A. White[13] claim to have shown previously that increased adrenal cortical secretion accelerates the release of antibody from the lymphoid tissue of immunized rabbits, and that this result is due to the dissolution of lymphocytes, of which there is evidence, both histological and in the form of a lymphopenia. Further to support this proposition, they immunized rabbits and mice against sheep's red cells, waited some months until antibody was no longer demonstrable in their serum, and then gave a single dose of adrenal cortical extract or pituitary adrenotrophic hormone. Within a few hours a high titre of antibody to sheep's cells was reached in the blood. In adrenalectomized mice this effect was not produced. This anamnestic reaction also followed injections of potassium arsenite or benzene—substances which, according to these authors, also stimulate the adrenal cortex and cause lymphocyte dissolution and lymphopenia. The subject has been approached from another point of view by E. H. Kass,[14] using human material. Arguing that if lymphocytes are a source of antibody globulins they should normally contain γ globulin, he devised a method of determining whether this is so. An antibody to pure human γ globulin was obtained by immunizing rabbits, and tested against an extract of normal human lymphocytes obtained from mesenteric lymph nodes and freed entirely by washing from serum proteins. Not only did these react, but the cell extract absorbed antibody from the serum, and extracts of other tissues did not react with it. All these interesting studies point conclusively to the lymphocyte as the source of antibody, but it should be remembered that some years ago Florence Sabin,[15] using a most ingenious and striking method of observation, obtained evidence that antibody is formed by macrophages, or "clasmatocytes" as they were once called from their habit of shedding fragments of cytoplasm—this being the process by which, according to Sabin, antibody is released.

SALICYLATE AND PANTOTHENATE

Much has been heard during recent years of the antagonism between sulphanilamide and its analogue *p*-aminobenzoic acid, and of the similar one between pantothenate and the related compound pantoyltaurine. It has generally been considered that the drug (sulphanilamide) blocks combination of an enzyme with *p*-aminobenzoic acid, and that pantoyltaurine blocks a combination of the same type with pantothenate. Attention has been drawn by Ivánovics[16] to a superficially similar antagonism between pantothenate and salicylic acid. Briefly, he has found that salicylate, even in dilution as high as M/1,000, will prevent the growth of bacteria which synthesize pantothenate—e.g., *Staph. aureus* and *Bact. coli*. If pantothenate is added to the cultures the antibacterial action of the salicylate is destroyed, there being a rough quantitative relation between the concentrations of the two compounds concerned in the reaction. When salicylate is added to cultures of some organism which does not produce pantothenate—e.g., *Proteus morgani*—salicylate does not prevent growth (until the concentration is as high as M/40), and the addition of pantothenic acid causes no increase of growth. It is concluded that salicylate interrupts some vital chain of chemical reactions which eventually leads in staphylococci and in *Bact. coli* to the synthesis of pantothenate. This antagonism is accordingly somewhat different from the classical antagonism between sulphanilamide and *p*-aminobenzoic acid.

The main interest of this investigation concerns the biochemist, but the clinician may well consider it in case it provides an explanation to the vexed question of how and why salicylate allays the swelling of the joints and other symptoms which appear in acute rheumatic fever. At present there is no evidence on this subject, nor is it easy to propound a plausible hypothesis to explain this problem of rheumatic fever. The best way of studying it would be to undertake a small clinical experiment. Two groups of patients suffering from acute rheumatic fever would be formed by selecting alternate patients. One group (the control group) would receive the standard course of treatment with salicylate. The other group would be given the same course of salicylate plus large regular doses of pantothenate. If the antagonism between salicylate and pantothenate which occurs with bacteria occurs also in man, it would be expected that the pantothenate would abolish the therapeutic action of salicylate. Such a demonstration would have no immediate clinical application, but it might prove an important starting-point for the further investigation of rheumatic fever. If pantothenate had no effect on the therapeutic action of salicylate, then one would have to conclude that pantothenate played no significant part in the production of the signs and symptoms of acute rheumatic fever.

VITAMIN K IN URTICARIA

Urticaria is the result of a sudden extravasation of fluid from the capillaries, and it may result from diverse causes. In Becker and Obermayer's[1] classification the first group comprises localized urticaria caused by external irritants such as the sting of insects or the nettle after which the disease is named. The second group comprises urticaria produced locally in response to the action of heat, light, or cold, or as a result of trauma. The third group comprises urticaria of internal origin produced by substances which reach the skin via the blood stream, such as foods, medicaments, inhaled allergens, or bacterial products from septic foci. The final and largest group is ascribed to "nervous exhaustion" or emotional upsets. The emotional urticarias are closely related to the second group or physical allergies, in which the patient is hypersusceptible to physical agencies such as cold. Some of the phenomena in urticaria have been closely studied by Sir Thomas Lewis and his pupils,[2] who have related the wheals to the stimulation of cholinergic nerves and the release of H-substance. Treatment has hitherto been mainly concerned with the removal or neutralization of the mental or physical stimuli believed to provoke the attacks.

A quite different approach has been made by Black,[3] who was stimulated by Howell's[4] suggestion that prothrombin and fibrinogen are constantly being formed and consumed in the blood, probably forming fibrin which in some way provides nourishment or protection for the cells of the capillary walls. Black was thus led to study the prothrombin content of the blood in urticaria and the therapeutic action of vitamin K. The study was confined to 156 patients in whom the disease was chronic and who had not obtained relief from trial diets, search for infections and allergens, or avoidance of drugs. These chronic cases represented just over half of all the patients with urticaria seen during the period of study. A diminished level of prothrombin was found in 65% of the patients. In some instances the diminution was notable, as the prothrombin times were twice as long as normal. It is a pity that the results were not presented in statistical form. Treatment was carried out with vitamin K by mouth, in the form of menaphthone, *B.P.*, 2 mg. thrice daily before meals. The addition of bile salts was found to be unnecessary. Relief was obtained in more than 60% of cases. It occurred most frequently in those patients in whom the coagulation time was prolonged. The duration of treatment varied from one to four weeks, and in many instances lesions ceased to appear after two days of treatment. Relapses occurred in about one-third of the patients, but the patients were again relieved by administration of the vitamin. These are considerable claims to make for a new and simple treatment for chronic urticaria, and it will be interesting to discover whether others have the same success as Black.

The Central Medical War Committee is informed by the Director-General, Army Medical Services, that instructions have now been issued for the release of medical officers in Groups 12 to 16 to be effected before the middle of October.

"ORTHOPAEDIC" REHABILITATION

BY

F. G. WARD, F.R.C.S.
Surg. Lieut.-Cmdr., R.N.V.R.

Function in the human body is dependent on use. If a limb is not used it withers. By immobilizing a part of the body in the treatment of a skeletal injury we are inviting it to wither. We now realize that loss of function during immobilization can be minimized and ultimate recovery speeded to completion by supervised active exercise. The first objective therefore is *maintenance.* Muscle-wasting and loss of blood supply in immobilized joints must be kept to a minimum during the fixation period by regular active muscular exercise. The second objective, which emerges when fixation is removed, is *restoration of function* by redeveloping power, mobility, and co-ordination in the injured part. Experience has shown that, generally speaking, the redevelopment of muscular power is the most important of the three. Muscle fibres obey the "all or none law"; to ensure, therefore, that every fibre is brought into play exercises should be performed with the maximum of effort, well sustained, and followed by a period of relaxation. Thus with a leg in plaster light movements of the toes are a waste of time. The toes must regularly be tightly flexed and vigorously extended.

For the patient in bed the simplest exercises suffice; but they must be supervised. The responsibility for seeing that they are carried out rests with the ward sister, but it has been found satisfactory to train a nurse in each ward to teach and supervise the exercises and see that they are carried out regularly. Five minutes every hour, at the hour, is the ideal. In the ambulant stage, when function is more advanced and the exercises become more complex, they can best be supervised by a P. and R.T. instructor, particularly as much of the work is done in groups or classes.

The physiotherapist is also concerned principally with active exercises, and his roles are "facilitation" and "re-education." "Facilitation" implies the treatment of the inhibitory factors of pain and stiffness. In this connexion the paraffin-wax bath has been found very satisfactory. "Re-education" embraces the treatment of weak muscles in all types of disability, from the flicker of recovery after paralysis to temporary inhibition by operation. Special apparatus is not essential for this, but some form of frame for the suspension of the affected limb in slings is useful; for, in a limb so suspended, gravity and the muscles needed to counter it are eliminated, allowing even the weakest muscles to produce movement (Guthrie-Smith, 1944). The exercises *must* be progressively graded up in power and duration as the muscle recovers, to ensure that the patient doesn't get the chance to use sling suspension as a convenient form of rest cure. The frame is also useful for the attachment of helical springs for resisted exercises.

Occupation is the ideal method of restoring mobility and co-ordination, and is especially applicable to wrist and hand injuries, but in spite of ingenious adaptations (Colson, 1944) its contribution to the redevelopment of muscular power is not comparable to that of active exercises. The diversional forms of occupation are invaluable for maintaining the patient's interest and morale, particularly when he is in bed. After he gets up, and before he is fit for a full day's rehabilitation programme, the remedial forms of occupational therapy can well be interspersed between prescribed exercise periods.

The following notes are based on experience at a Royal Naval hospital and its annexed orthopaedic rehabilitation centre.

The Shoulder and Upper Limbs

For the *shoulder,* mobility is as important as power. Full elevation is almost impossible in the absence of external rotation. The patient's active efforts in this direction (the elbow being flexed), both with the arm at the side and with it abducted, are necessary throughout treatment. While the arm is still in a sling, exercises are confined to deltoid bracing and easy external rotation movements. When the sling is first discarded, the resistance of gravity is diminished by doing rotary and swinging exercises in a stooping position and by exercising in sling suspension. Resistance is gradually introduced—in the former by increasing the amplitude of movement, and in the latter by varying the point of suspension and using springs. Once the arm can be abducted to the right-angle against gravity, special apparatus can be dispensed with, and nothing more complex than balls and broomsticks is needed to lend variety to the exercise routines. The good arm, which should be exercised with the injured one from the start, is used both to assist the movement of the latter and to redevelop power by resisting it. As function improves, increasing attention is paid to overhead work in exercises and in games. Most such games are the fruit of the instructor's invention, but volley-ball is both remedial and popular. The tendency to spare the injured arm is countered by employing two-handed games whenever possible. Heavy bouncing balls provide excellent shoulder exercise, particularly in the later stages, for they encourage increased mobility by "impulsive action," as advocated by Mr. Ernest Griffiths (1943). Rhythmic arm-swinging exercises have a place in the early treatment of stiff shoulders, but later are mainly used as a form of respite between spells of hard muscular work.

The *elbow-joint* is very slow to recover its mobility. Mobility is achieved by *active* movement only—i.e., by the contractions of biceps and brachialis or triceps. These efforts must be purposeful, and be persisted in at frequent intervals throughout the day. Any attempt at passive stretching sets up a vicious circle of strain, tissue-effusion, and organization, resulting in diminution of elbow mobility. Mobility at the radio-ulnar joints is achieved by good orthopaedics rather than by late rehabilitation. In the treatment of stiff elbows the aim is so to develop muscular power as to minimize the risk of further elbow strain, and to return the patient to duty, with the encouragement that, if he works at it *actively,* mobility will continue to improve slowly even over many months. Power is developed first by the active efforts to regain mobility and later by resisted exercises within the existing range of mobility. The best resistance is the patient's other hand, but press-ups and pull-ups, starting with the body nearly vertical and the arms horizontal, using any convenient furniture, can be performed under supervision provided that the elbow is *never* strained beyond its existing range by the resisting force. Rotation of the forearm can be resisted by the patient's other hand, but Mennell's "wrist roller" is a useful adjunct.

In the absence of muscle or tendon adhesions in the forearm, gripping exercises, small-ball games, and simple manual work are usually sufficient to restore function in a stiff *wrist,* but the painful wrist taxes the skill and patience of the physiotherapist to the utmost. Broadly speaking, the treatment consists in supervised active movements by each muscle or muscle group in turn, combined with palliation, in the form of heat, for the pain.

Stiff *fingers* are very slow to regain mobility, but the stiffness does respond to active exercises, and contractures may often be reduced by elastic traction. These conditions are easier to prevent than to cure, and the problem is therefore one of orthopaedics rather than rehabilitation. Any fingers that do not have to be fixed should be not only moved but *used.* For exercises each stiff joint must be isolated in turn by an assistant or by the patient's other hand, and the maximum effort made to flex and extend it. These exercises should be preceded by a soaking in very hot water, or, better, in a paraffin-wax bath, though caution must be observed with anaesthetic hands. For the thumb, opposition is the most important movement, and persistent attempts must be made by the patient to oppose it to each finger-tip in turn. Simple games with a tennis-ball, such as spinning and bouncing it against a wall, help to mobilize stiff hands. (The uninjured hand should not be used.) Occupation is the ideal treatment provided the hand be kept warm. Occupational therapy provides a wide variety of graded movements for stiff hands and finds in them its best application, but there is a tendency among occupational therapists to expect too skilful work of stiff hands, and in the earlier stages simple manual work is the best treatment, tool-handles being padded if necessary.

The Lower Limbs

A strong and mobile *foot* is essential to full recovery in any lower-limb injury. If foot exercises are neglected the results are not immediately apparent, but at a later stage of recovery some trivial injury is apt to set up a condition of foot-strain, necessitating a slowing down of activity at the very moment when it should be stepped up to the maximum. Foot exercises, particularly inversion and toe flexion, must be performed regularly and with maximum effort throughout the recumbent and early weight-bearing stages of treatment. Only the latter can be done in plaster, but the effort of inversion should still be made. If these exercises, dull though they be, are well performed the subsequent recovery of ankle movement and control of oedema are greatly accelerated.

Some degree of stiffness and weakness of the *ankle* is inevitable after the use of leg plasters. Oedema is the most potent cause of their persistence. This requires complete control from the start, and crêpe bandaging is rarely adequate. A bandage of Unna's type is needed. This must extend from the toes to the tibial tubercle and exert firm pressure below the malleoli. Formal ankle exercises have a place in the early mobilization stage, but as soon as limited weight-bearing is allowed they are replaced by any exercises that the instructor can devise to redevelop the feeling of spring in the foot and ankle. Backward springing is easier than forward, as less ankle movement is required, and this should be attempted first: it should be combined with backward bracing of the knee. Springy walking is next introduced, using the arms freely for extra momentum in the spring. Other suitable exercises that can be worked in are "shadow-boxing" and "running starts" against the wall. Activity is the keynote of the later stages. Games such as volley-ball can be introduced early, and cycling is also of great value provided the toe and not the heel is placed on the pedal. Ballroom dancing is another good exercise, and does much to restore the patient's confidence in his leg. The timing of progress is very important in these cases and can only be learnt from experience. It does not pay to get them on to a routine of unrestricted weight-bearing too soon, but if the foundations of a strong and mobile foot are well laid any remaining ankle stiffness and weakness usually recover quickly in the later, "activity" stages of treatment.

The shape of the articular surfaces of the *knee* makes no contribution to its stability, and the ligaments, though very strong, are insufficient to resist even the normal strains of activity; the stability of the knee therefore depends on the power of the thigh muscles. The hamstrings probably make some contribution, but it is principally the quadriceps femoris that embraces and stabilizes the knee-joint. Wasting occurs in this muscle after injury to the joint, and the component that is first to waste and last to recover is the vastus internus. The muscle fibres of this extend almost down to the knee-joint, and it comes fully into play only in the last 10° of extension. Some degree of disuse-wasting after above-knee plasters is therefore inevitable. Quadriceps exercises are essential to recovery from any knee injury or operation. Some patients experience difficulty in bracing the quadriceps of even a normal knee, and if meniscectomy is contemplated the knack of quadriceps bracing must be learnt *before* operation. After operation or injury quadriceps exercises are started as soon as possible, even on the same evening, and are continued hourly throughout the ensuing days. The power of active contraction usually returns quickly, though the vastus internus rarely recovers within 48 hours. The best way to bring it into action is to brace the knee back at the same time as the foot is strongly dorsiflexed and inverted. Straight leg-raising is a good exercise, provided the leg is held absolutely straight by quadriceps bracing, but it is painful in the early stages, and there need be no hurry to start it provided bracing is well performed. The recently operated knee is intolerant of weight-bearing, and the 14th day is quite soon enough for the average patient to start getting up, knee flexion having been permitted for the previous two days. Three weeks is early enough to start deliberate knee flexion and hamstring exercises, though static cycles with light resistance may be used sooner. When the patient is able to get up all day the hourly exercise routine becomes impracticable, but exercises can be performed for longer periods at less frequent intervals (20 minutes, 3 or 4 times a day). These are at first done sitting or lying down, but as muscle power returns light weight-bearing exercises are begun under a P. and R.T. instructor, though the emphasis is still on quadriceps exercises. Finally the patient progresses to an active P.T. class, in which he learns to run and jump. In the majority of cases full confidence is regained by the sixth week, though it takes some two or three months for the knee to feel quite normal again.

The stiff "femur knee" is a different problem. Here we are dealing with a "quiet" joint which will tolerate a fair amount of passive straining provided that the strain is applied only by the patient's own efforts. At the same time it is almost invariable to find the patella bound down to the femur. The patella normally mobilizes slowly with daily passive manipulation after heat treatment. Manipulation of the knee under anaesthesia may be needed in selected cases. The static cycles with adjustable pedals are particularly useful in this type of case. Here again quadriceps maintenance and redevelopment are of prime importance. Two useful indices of adequate quadriceps recovery are the ability to maintain a straight knee against a pull of 40 lb., measured by a spring balance applied at the ankle, and the ability to run a zig-zag or figure-of-eight course without pain in the knee.

The *hip-joint* is occasionally involved by direct or adjacent injury, but more commonly its muscular control is weakened after treatment in abduction by plaster or traction for fractures of the femur. Stiffness responds to simple exercises and, in any case, apart from loss of extension, causes only minor disability. Muscular weakness, however, is a major factor in the persistence of the "calliper gait." Power is restored by regular resisted exercises, using sandbags or a simple weight-and-pulley mechanism, and also by suitably graded active P.T., games, and rambles.

The action of *normal walking* requires mobile toes, at least 10° dorsiflexion at the ankle, 70° flexion of the knee, and a small but adequately controlled range of movement at the hip. The basis of normal walking is correct placing of the foot. Any deviation in direction and position of the foot as compared with the normal limb throws the mechanism out of gear and results in a limp. The weight of the body is not transferred direct from heel to toes, but passes along the outer border of the foot and thence across to the ball of the great toe, producing a rolling action. This action can be taught as a dissected movement as early as the non-weight-bearing, sitting stage as advocated by Mennell (1940), but, provided the power of inversion of the foot and the control of the toes are restored, the normal rolling action is recovered naturally. If the foot is placed outside the line of march the trunk has to bend over it to maintain balance, hence the typical "calliper gait." Even if the foot is correctly placed the glutei may be too weak to maintain the hip in a position outside the line of the foot, though this failing is more commonly due to the muscles having lost the "feel" of the normal gait. Before normal walking can be expected the patient must learn to stand on the injured leg alone without deviation of the body, and he must then learn to keep this position as the good leg swings forward. Walking with a stiff knee is often a residual habit, and is usually countered by bringing the injured leg forward with a slight kicking action. These fundamentals of walking should be taught at the restricted weight-bearing stage, when the patient is taking part of his weight on his arms, using a chair, wall-bars, etc. At the full weight-bearing stage it should not be necessary to do more than redevelop the spring from the foot and ankle, and correct minor deviations with the aid of a full-length mirror and a painted line on the floor.

Re-education in *running* can be begun at the partial weight-bearing stage. With part of the body weight supported by the hands and the body inclined a little forward, the patient is taught to mark time with a running action, getting a slight bounce off the balls of his feet but keeping his toes on the floor. The movement must be symmetrical, the good leg gearing down to the strength of the injured one. The amplitude is gradually increased till the toes leave the floor without breaking the rhythm and without a deliberate attempt to lift them. At the full weight-bearing stage the exercise is repeated without support, the arms swinging close to the chest as in running, and progressing to standing running, backward running, normal running, and sprinting. An even rhythm must be maintained; if the rhythm is broken the exercise must be restarted at an earlier stage and worked up again.

The Trunk

An uncomplicated case of compression fracture of the *spine* is fit for advanced activity almost as soon as the patient has become accustomed to his plaster jacket. Exercises are directed to the maintenance and further development of the erector spinae group and abdominal muscles, to progress from single to two-leg raising, and in trunk-raising, first with the hands clasped behind the back and then successively with arms at the sides, hips firm, "neck rest," held above the head, and finally holding increasing weights above the head. These exercises are further performed lying with the thighs across a stool, the legs being held by an assistant; and they are supplemented by very strong backward bracing. It is of the utmost importance that the back muscles should be very strongly developed *while the back is still immobilized in plaster.* After removal of the jacket the patient requires about 48 hours of light informal mobilizing exercises (swimming is suitable) before returning to the routine of the "spine group." Apart from "unrolling," specific flexion exercises are best avoided for the next two weeks. After hyperextension plasters, posture always requires attention, and the exaggerated lordosis should be corrected by abdominal contractions combined with tensing of the buttocks. Progressively active games, including the use of heavy medicine balls, are good for mobilization and for the re-creation of confidence, and the routine should progress to include really heavy manual work for increasing time periods, the best of which is the use of axes, sledge-hammers, and cross-cut saws. Suitably treated, these cases carry an excellent prognosis (rather less favourable in the comminuted than in the "concertina" types of fracture); but, in spite of strong mobile spines, minor symptoms, particularly low back pain on prolonged sitting, sometimes persist for some months, though these rarely render a man unfit to carry out his duties.

Cases of *"sciatica" and low back pain* are troublesome to treat, particularly as many are of long standing and tend to develop a considerable functional overlay. They are rarely suitable subjects for the active routine of the rehabilitation centre, but they do benefit from extensor and abdominal exercises, so far as these can be performed. The increase in muscle power and activity helps to eliminate some of the psychological disability. Many such cases are treated in plaster jackets applied with head suspension, and this often gives complete relief from symptoms. They can then be treated in a class with the fractured spines in plaster and, the inhibitory factor of pain being eliminated, muscular development and general well-being can be more rapidly re-established.

Conclusion

Prescription, both in quality and in dosage, is as important in rehabilitation as medicine, and just as each dose is duly measured by the sister, so should the exercises be supervised. The personal interest of one individual in the person and progress of the patient means a great deal to him. This individual need be no more exalted than the nurse or instructor detailed to supervise the exercises. The doctor's active interest in the patient's progress, backed by regular accurate measurements, is essential, and he should ensure that the exercises are being done according to his instructions. The organization of the hospital, and the rehabilitation centre, are ideal for the purpose, but this treatment is no less important in domiciliary practice. In the absence of adequate supervision such exercises can embody only the bare essentials.

The Rehabilitation Workshop Scheme organized in Birmingham (Colson, 1944) is a vital contribution to rehabilitation in industry. The methods employed are clearly not applicable to the household, but suitably chosen manual occupation has its place in domiciliary practice, and the little extra trouble involved is likely to pay good dividends.

Summary

Orthopaedic rehabilitation is largely a matter of *maintaining* the existing power and activity of muscles.

The roles of ward sister, P.T. instructor, physiotherapist, and occupational therapist are discussed.

Rehabilitation methods based on experience at a Royal Naval hospital and its annexed orthopaedic rehabilitation centre are described.

The importance of prescription and of personal interest in the individual patient is emphasized, and a plea is put forward for the inclusion of active rehabilitation in the treatment of injuries in domiciliary practice.

I wish to thank Surg. Lieut. A. McKelvie, R.N.V.R., for his assistance in the final draft, and to acknowledge with gratitude the encouragement and advice of Dr. H. E. Moore, Consultant in Rehabilitation to the Royal Navy, many of whose ideas are embodied in this paper. I also wish to thank Surg. Rear-Adml. R. F. P. Cory for permission to offer this paper for publication.

INTERNATIONAL SOCIETY OF SURGERY

The activities of the International Society of Surgery have necessarily been largely in abeyance during the war, but now that hostilities in Europe have come to an end there are promising signs of resuscitation. During the meeting of the Association of Surgeons at the Royal College of Surgeons in May there was an informal gathering of those Brtitish members of the International Society who happened to be in London then. They were very glad to welcome Dr. Leopold Mayer, of Brussels, the president-elect of the International Society of Surgery, and other Belgian and American members who were guests at the meeting. The steps taken by the American committee to hold the Society together in that country during the war years were explained, and it was recognized that these were only a temporary war measure designed to keep the Society alive and its interests revived. A meeting of the International Committee is to be held as soon as this can be arranged, and there is some hope that the full meeting of the Society, which was originally planned to take place in Stockholm in 1941, may be held in that city in 1947. Meanwhile, the surviving officers who were elected at the Congress held in Brussels in 1938 will continue to act and conduct the affairs of the Society strictly according to the constitution. Prof. Grey Turner is the British delegate on the International Committee.

ROCKEFELLER FELLOWSHIPS IN PREVENTIVE MEDICINE

The Rockefeller Foundation is prepared to award a small number of Fellowships to enable medical men and women wishing to take up public health as a career to engage in special studies for this purpose. The Fellowships, which will be open to British-born subjects holding a university degree in medicine registrable in the United Kingdom, will normally be awarded for two years, and the annual value will be between £450 and £800, travelling expenses being paid during residence abroad. Candidates should have had some general clinical experience since registration, and service with the Forces will be taken into account.

The conditions of tenure provide that normally a Fellow will be required to study preventive medicine for not less than one year at the London School of Hygiene and Tropical Medicine, taking part in teaching and demonstration and devoting himself to some special investigation approved by the committee of award. He will be given an opportunity of taking the D.P.H. For part of his tenure he will be expected to study at suitable institutions abroad, and arrangements will be made by the Rockefeller Foundation for this purpose. He will be required to keep a daily record of his work for submission as requested by the committee of award, which will have power to terminate his Fellowship if obligations under it are neglected. No other award may be held, and no other work, paid or unpaid, may be undertaken at the same time as the Fellowship without permission. Candidates should write informally to the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1, giving date and place of birth, full details of school and university education, including qualifications and present and past appointments, and full particulars about themselves, their work during the war, and plans for the future. The names of two referees should also be given. Medical officers with the Forces may apply now for Fellowships tenable on demobilization.

ARGENTINE–BRITISH MEDICAL CENTRE IN BUENOS AIRES

An Argentine–British Medical Centre has been established in Buenos Aires, with the assistance of the British Council, to promote closer relations and to facilitate the exchange of information between the British and Argentine medical professions. The Centre has a Committee of Honour, the twenty-two Argentinian members of which include Prof. José Arce, Prof. Pedro Escudero, Prof. B. A. Houssay, and Prof. Alfredo Sordelli; British representatives of various branches of medicine have been invited to join this committee. On the executive committee are the President of the Centre (Dr. Mariano R. Castex), the director (Dr. Antonio Egües), the secretary (Dr. R. Castro O'Connor), an assistant secretary, three ordinary members, and two representatives of the British Hospital in Buenos Aires.

The Centre's library contains a selection of the most important British medical journals and up-to-date textbooks. When an inquiry cannot be answered on the spot the Centre obtains information, articles, and books (or photostat copies) from Britain through the British Council. Among the activities are distribution of the *British Medical Bulletin* (Spanish edition), supply of medical films, translations from English into Spanish and Spanish into English, and certain facilities for members wishing to subscribe to British medical journals or buy British medical books. Members of the Centre pay an annual subscription, and additional charges are made for such special services as the provision of photostat copies. The facilities are available to doctors in the interior of Argentina, who, since they are not in a position to borrow original books and articles, are supplied with photostat copies. English classes, in which the emphasis is on conversation and the reading of medical books, are an important and very popular feature.

BRITISH ASSOCIATION OF UROLOGICAL SURGEONS

At the first annual general meeting of the British Association of Urological Surgeons, which was held at the Royal College of Surgeons, London, on June 29, it was announced that the following had accepted honorary membership: Sir C. A. K. Ball, Surg. Rear-Admiral G. Gordon-Taylor, Sir Hugh Lett, Mr. Cyril Nitch, Mr. A. Ralph Thompson, Prof. G. Grey Turner, Mr. Henry Wade, Sir Alfred Webb-Johnson, P.R.C.S., and Surg. Rear-Admiral R. J. Willan. Seventy Home Foundation Members had been elected, and names were accepted of five honorary members, forty-eight full members, and ten associate members from over-seas. The constitution of the association was confirmed and the rules were approved. Prof. Fey, professor of clinical urology in the University of Paris, was welcomed as a visitor, and was elected an honorary member. In the afternoon, by kind permission of Major-Gen. H. H. Blake, the members went to the Spinal Injury Centre, Stoke Mandeville Hospital. After a brief discussion on the work of the centre, the party visited the wards, the physiotherapy and occupational therapy departments, and the gymnasium, where there were demonstrations of selected cases.

Nova et Vetera

A PORTRAIT OF CHARCOT

Charcot, who was a friend of Alphonse Daudet, was one of Léon Daudet's sponsors when he entered the Paris school of medicine. Léon Daudet[1] describes Charcot as resembling a stout Napoleon, who tyrannized over those about him and spoke to them in imperious and often ironical tones. Daudet, as have many others, speaks of his genius as a clinical diagnostician. But his patients were to him little more than puppets, who were the convenient objects of an intellectual exercise. Daudet describes him as "pitiless" towards human beings but sentimental towards animals—a familiar combination—and as treating his many dogs as if they were children. His knowledge of the great poets, of the philosophers, and of European painting was extensive, and he brought to bear upon his own subject the same detached and analytic intellect, disdaining therapeutic intervention. His views on religion were those of an agnostic, for which, together with his inflexible faith in democracy and the benefits of the Revolution, he earns Daudet's censure. He is said to have declared that only one titled person had ever had any intelligence—a Dr. de Sinety, the author of "a remarkable work on the liver in nursing mothers."

One of Charcot's greatest weaknesses was his intolerance of contradiction or criticism, which he countered by ferocity or by sustained campaigns of petty persecution. He was a tireless worker, and would sometimes spend most of the night preparing a diagram or illustrative figure. Stupidity exasperated him, and yet his fear of competition caused him to gather round him professional mediocrities. In compensation, he found much pleasure in the society of the writers and artists who were constant visitors to his house. He was a devoted and tolerant father, and allowed his sons and daughters to make the house resound with their noisy games and laughter, often to the discomfiture of the nervous wrecks who waited to consult him in a drawing-room equipped with stained-glass windows and pseudo-mediaeval furniture. Daudet, perhaps with picturesque exaggeration, describes patients from the far corners of the earth writhing about on strangely shaped prayer-stools, or sitting with their atrophied limbs stretched on chairs decorated with gargoyles—waiting to receive their prescription for nux vomica or bromide from the Master.

In his dealings with patients Charcot did not hesitate to give expression to a savage, and often deliberately obscene, sense of humour. He is said to have told a neurasthenic: "You are like a man sitting on a dung heap with a sword suspended over his head; you must either get under the manure or lose your life." Charcot read English, German, Spanish, and Italian, and his library contained, in addition to a large literature of mental disease, many works on magic and demonology. The presence of works in the latter category gives an additional key to Charcot's character. It is clear that in an age when science was invested with a romantic popular interest he was victim to the idea of himself as a maker of magic—as one able to predict the workings of the hidden forces of Nature and influence the behaviour and fate of other men. He had a paranoid disposition. At his famous clinic at the Salpêtrière Charcot was brusque to staff, students, distinguished visitors, and patients alike. His clinical demonstrations were stage-productions, spiced with literary and artistic allusions. Daudet says that Germans bored him, but that he showed a liking for English and Russian visitors. In 1890 he was at the height of fame and influence, and it was in this year, during a gay Christmas Eve party, that he was seized with an attack of acute precordial pain. Daudet, who was present, ran across the road to fetch Prof. Potain. It was two o'clock in the morning, and Potain answered the summons in his night-shirt. Slipping on trousers and a fur coat, he came to the aid of his distinguished colleague, spending fifteen minutes alone with him. On emerging from Charcot's room Potain pronounced the trouble to be of gastric origin, but as the young Daudet walked back with him, he said: "I had to reassure him, he thought it was angina pectoris"; adding after a pause, "He was not wrong." Deeply distressed, Daudet asked: "How long will it be, sir?" Potain replied: "Two years, two years and a half at the most." On the following day Charcot had recovered, but in 1893 Potain's prognosis was fulfilled.

N. H. J.

THOMAS BILL, M.D.: PHYSICIAN TO HENRY VIII AND EDWARD VI

The following details about this physician, in addition to those recorded by Munk in the *Roll of the Royal College of Physicians*, may be of interest.

Munk states that he was of Bedfordshire and that he took his M.D. from Pavia, but Venn, in *Alumni Cantabrigienses*, gives him as the son of John Bill, of Ashwell, Herts, and as M.D. of Padua. He also states that a pedigree of the family is in Cussaus's *History of Herts*. I have not seen this, but can state that there is no mention of Thomas Bill in either Sir Henry Chauncy's or in Clutterbuck's History of the County. Among other monastic plunder he obtained in 1542, as we learn from the State Papers of the period, the rights over certain fisheries in the Trent and in the pool called Depedraught, beside the Monastery of Burton-upon-Trent, formerly reserved to the Monastery. There was also a tenement within the close of St. Bartholomewe beside Smithfield, lately the property of Bart's, which he secured in June of the same year. In the next year he had a grant of St. Sepulchre's Rectory, London, late the property of Bart's.

In 1548 we get the letter, referred to by Munk, from Princess Elizabeth (afterwards Queen Elizabeth) to Somerset, thanking him for his care and for sending Dr. Bill to her in her sickness. Bill died in 1551, and is entered as Phisition to the King's Majesty on the Probate Books. The following is an abstract of his will:

(*P.C.C. Powell 7.*) Soul to God. Body in church or churchyard where I may die. To the poor at my buriall, £4. The Parson of Sacam, Co. Herts, 3/4. The Poor there, 6/8. Poor of great St. Barts, 6/8. Servants 10/- each. To my mother, 20/-. Brother John Bill, and his wife, brother Samuel, and his wife, Brother Gosnolde, and his wife, 6/8 each. Brother William Bill, D.D. my prebend called Mylton in Oxon, belonging to the church of Lincoln. To wife, Agnes, my house and garden in great St. Barts for life, then to my daughter, Margaret and her heirs. To wife, woods, etc., called Rowney Lands in Herts, then to daughter, Margaret: lease of grayne, corne in Cropthorne and Everbury, Co. Worcester, late of the Priory of Worcester held for 21 years of the Court of Augmentations, now let to Raffe Parsones for 19 years. Lease of the farm at Sacam to wife for life then to daughter, Margaret. Manors of Higham and Lelychurche in Kent leased me by St. John's College, Cambridge. To Margaret 1/3rd of plate and household stuff, etc. Wife Agnes, Brother John Bill, and Brother-in-law Richard Tebolde of Kemsynge, executors. 4 witnesses.

Bill's wife was Agnes, sister of Richard Tebolde, of Kemsing, Kent. Brother Gosnolde was his brother-in-law, Thomas Gosnold, of London, grocer. Munk hints that William Bill was his younger brother and that the college granted him the manor of Higham when William Bill was Master of St. John's. William certainly was the brother of the physician; he had a distinguished career in the Church, ending up as Dean of Westminster, where he is buried in the Abbey.

R. R. J.

AN ACADEMY OF MEDICINE

Although medical societies flourished in Paris before the Revolution and, under Bonaparte, an Academy of Medicine was constituted it did not long survive; the existing Academy of Medicine was created by ordinance of Louis XVIII on Dec. 20, 1820, and in 1920 its centenary was celebrated. The proceedings are recorded in a handsome volume,[1] and, in view of recent correspondence in the medical and lay press, it may be interesting to refer to some points in the history of the Academy of Medicine.

The primary duty of the Academy, prescribed in the ordinance of 1820, was "to answer questions of the Government on all matters relating to Public Health, especially on epidemics, diseases peculiar to particular countries, epizootics, questions of legal medicine, the distribution of vaccine, the investigation of new remedies and secret remedies, internal and external, mineral waters, natural and artificial, etc." The Academy was also charged with the continuation of the researches of a former Royal Society of Medicine and of a former Royal Academy of Surgery in the whole field of the healing art. The administrative details prescribed in the original constitution were varied from time to time, but the number of ordinary members, fixed at 100 by an *arrêté* of 1835, has not been changed. The membership of a society may be limited either directly, in this way, or indirectly, by admitting a fixed number of new members at regular intervals. The former method has not been much used in learned societies in this country; the other method is adopted by the Royal Society of London; it will not, of course, ensure an absolute constancy of the number of members, but, unless the death rate rises or falls continuously, the society will, after initial fluctuations, keep a fairly steady level of population.

---

[1] *Memoirs of Léon Daudet*, edited and translated by A. K. Griggs. London, 1926.

[1] *Centenaire de l'Académie de Médecine, 1820-1920.* Paris: Masson, 1921, pp. 277.

The fixed population of the Paris Academy of Medicine is a very small fraction of the population of the medical and allied professions in France, and in the nature of things so small a body must tend to be an order of merit; it will therefore consist of men of established reputations not usually young. The Academy of Medicine, however, is not simply an order of merit; it is assigned definite responsibilities. In the centenary addresses of Vaillard (mainly concerned with public health, bacteriology, and epidemiology), of Chauffard (on general medicine), and of Delorme (on general surgery) we have a heartening account of French contributions to the science and art of medicine. How far the Academy, as such, initiated these is not easy to say. Indeed a reader may sometimes have doubts. In speaking of vaccinal syphilis Vaillard remarks: "Indeed the Academy was sometimes too slow in sanctioning new truths applicable to the protection of the public health." Elder statesmen do move rather slowly; perhaps wisely. One might expect that an order of merit would rarely be very insistent advocates of drastic reforms.

Reports of Societies

MANAGEMENT OF THE PERMANENT COLOSTOMY

A meeting of the Section of Proctology of the Royal Society of Medicine was held on July 18 for a discussion on the management of the permanent colostomy. Mr. F. McG. **LOUGHNANE**, who presided, said that the establishment of a colostomy was looked upon by the average patient as a tragedy. Moreover, many surgeons performed colostomies but by no means all gave their patients adequate guidance as to their management; hence the present discussion.

Mr. **ERNEST MILES** said that very few doctors appreciated the value of a daily wash-out of the colon for regulating bowel movement. Consequently when the patient was discharged from hospital he was left very much to his own devices, and it was small wonder that he got into trouble. Bowel action after colostomy could be controlled by a daily plain water wash-out at a temperature not exceeding 80° F. A higher temperature reduced the muscular tone of the colon, and caused part of the wash-out to be retained, with a sudden gush of fluid some hours later. He emphasized the necessity for absence of tension; everything should be easy and comfortable. The patient's belt should only be dispensed with at night when he was recumbent. The stump of the colostomy should be prevented from becoming stenosed by systematic dilatation.

Sir **CHARLES GORDON-WATSON** said that the management of colostomy had been much neglected. In the old days of lumbar colostomy its bad reputation might be understood, but he had operated on patients in every walk of life, and many of them had carried on their work in reasonable comfort and with only slight inconvenience. There were differences of opinion as to where a colostomy should be made. He liked to make it through the rectus muscle. The spur should be kept outside the abdominal wall for at least three weeks. Another point was not to make the opening too big; he always made it so that one could get one finger on either side of the glass rod. Sometimes the skin began to contract round the colostomy opening, and there was a tendency for the spur to be pushed back, so that faecal matter got into the cul-de-sac. Sufficient skin should be removed at the time of the primary incision to ensure that it did not get too close to the margin of the colostomy. If there was no obstruction he thought it wise not to open the colostomy before about the fifth day. Sometimes the opening through the rectus muscle stretched and the colostomy area herniated. This might be overcome by using a bigger disk on the colostomy belt; he never used cups. With regard to the wash-out, he liked to have a big tube, which should be passed very carefully and slowly. It was necessary to find out how much fluid the colon would hold. The amount varied very greatly; he had known as much as 5 pints go into the colon.

Danger of Perforation

Dr. W. B. **GABRIEL** drew attention to the seriousness of the risk of perforation of the colon in the wash-out region. After a colostomy had been satisfactorily established, whether terminal or loop, it must be decided whether the bowel was to be allowed to act naturally or a wash-out regime adopted. He had collected from St. Mark's Hospital the records of eight cases of perforation—six in males and two in females. One case occurred while the patient was still in hospital; the others were admitted as emergencies at different times after discharge varying from two days to 2¾ years. The case occurring two days after discharge was in a man aged 64 in whom some force had been used at a wash-out, the patient immediately complaining of severe pain. The doctor subsequently diagnosed peritonitis and sent him to hospital, where he was moribund on admission and died an hour later. Post-mortem examination revealed general peritonitis and a small perforation on the mesenteric border of the colon. Perforation usually occurred 2 in. to 2½ in. above the colostomy, and if the peritoneal cavity was entered gross contamination would result. Various causes might be held responsible for the perforation, such as the use of a large heavy tube or a tube made of hard inelastic rubber, and the possibility of inexperienced handling or injudicious force applied in passing the tube should always be borne in mind. There might also be local predisposing causes. In some cases the colon had an unduly thin wall and possibly diverticuli were present; the point of the tube or catheter might be lodged in the thin-walled sac and a very slight force would cause perforation. One point of interest was that all the patients concerned were over 60 years of age. The characteristic symptom was severe abdominal pain during or just after the wash-out and a rapidly developing peritonitis. Out of a total of nine such cases eight proved fatal.

Mr. E. T. C. **MILLIGAN** showed a number of lantern slides illustrating the linings in a colostomy, and spoke also of the time, patience, and team work needed in order to obtain the desired rhythm of one bowel action daily.

Technique of the Wash-out

Mr. **LAWRENCE ABEL** said that surgeons had been too hesitant in emphasizing to both patients and their doctors that the patient with a colostomy could obtain easy and perfect control. The secret of the control of the colostomy was the daily wash-out. The wash-out should start two or three days after the operation was performed, and the patient should be trained as to the quantity of plain water necessary to cause a proper colonic reflex. The question of breakfast needed a little consideration. When the patient woke up and drank a cup of tea he had a slight gastro-colonic impulse; he should be instructed to get out of bed and have his breakfast—preferably a square meal—immediately. That would result in a good flush down to the colon. There were cases which did not need a daily wash-out and could get the bowels regular without such an expedient, but it could not be known in advance which patients these would be, and every patient should start by having his morning wash-out after breaking his fast. The wash-out should if possible take place in a combined bathroom and w.c., and the patient be comfortable in a lounge chair. A soft rubber tube must be used. In over a thousand cases he had never seen a perforation with a peacetime rubber tube, but he had seen three cases with wartime rubber. It did not matter how cold the water was; cold water from the tap was best. The average patient should be in and out of the bathroom in half an hour. If the colostomy was an old-fashioned one it must be supported by a belt; if it was a modern colostomy a belt was not needed. The patient should have a lint pad, but the soft side must be used and greased with a little vaseline or zinc oxide ointment. If there was a cul-de-sac left it would accommodate faecal matter and should be washed out once a week. The patient should also be instructed to see the surgeon at regular intervals.

Mr. A. **Dickson Wright** said that breakfast in bed was a very good way of making a colostomy work. Some speakers had minimized the discomfort of a colostomy, but he had never found a patient other than delighted to say farewell to it. He described one man who had had a colostomy performed 15 years previously and had developed a hernia which was larger than the whole of his abdomen. He excised the affected gut and joined the descending colon on to the rectum, and the patient made an uninterrupted recovery. The hernia was quite manageable and the patient's whole existence was transformed.

Mr. H. J. **McCurrich** said that the cases of perforation which had been mentioned occurred apparently when the wash-out was done by a nurse or relative. If the patient was well trained, was perforation likely to occur if he did the wash-out himself? Dr. S. W. **Patterson** said that a number of patients did not need a wash-out and were able to get a steady and firm action of the bowel, though at certain times of the year, when fresh fruit and vegetables came in, they had to be particularly careful. In diverticulitis, where much more of the bowel was involved, it was sometimes necessary to make a transverse colostomy. Patients must not be allowed to think themselves social pariahs.

In some further discussion Dr. G. **Vilvandré** spoke in disapproval of transverse colostomy, and also emphasized the need for teaching young surgeons and radiologists the dangers which might attend passing the cathether into the gut. Mr. **Michael Smyth** mentioned the ease with which a colostomy might be closed.

MEETING ON SEMINOLOGY

A meeting of workers interested in seminology and other aspects of infertility was arranged by the Family Planning Association and held on July 14 and 15, by courtesy of the University authorities and of Dr. J. Hammond and Dr. A. Walton, at the School of Agriculture in Cambridge. The animal research workers opened the conference with some interesting papers and demonstrations on the metabolism of semen, on fertilization, and on early death of the fertilized ovum, and on the respiration of spermatozoa. Aspects of human seminology and the investigation of infertility were discussed by various medical workers.

Dr. **Margaret Hadley Jackson** gave a brief report of some of the work done at the Exeter F.P.A. clinic on semen analysis, and suggested a method which might be of value to clinicians in grading male fertility. She also discussed the post-coital test (including examination of the vaginal pool and cervical mucus), and stressed both its value in the investigation of cases of infertility and the ease with which it could be carried out. Between 600 and 700 such tests had been done at the clinic on most days in the cycle, and at times after coitus varying from half an hour to 12 days in both fertile and infertile wives. It was usually possible to find sperm, provided the test was repeated often enough within 12 to 15 hours after coitus, even when the husband had a sperm density as low as 2 or 3 millions per c.cm. Those cases in which the early post-coital test remained persistently and completely negative were rare, even in infertile couples, and Dr. Jackson produced evidence suggesting that tests done at longer intervals (40 hours or more after coitus) might provide a more valuable measure of adequate fertility.

Mrs. **Clare Harvey**, of Exeter University, in a paper on the interpretation of morphological abnormalities in human spermatozoa, suggested that most, if not all, abnormal types might be produced by degenerative changes in sperms which had been morphologically normal when first detached from the germinal epithelium. Evidence suggested that most morphologically abnormal spermatozoa were, in fact, aged spermatozoa. Most specimens produced a week or more after the previous ejaculation showed a higher abnormal count than those produced at shorter intervals. The average age of sperm population at ejaculation might be increased by delay in the journey from the testis through the epididymis and vas. There appeared to be a close relationship between the motility of the spermatozoa and their age. Figures from 130 recent semen analyses showed that in at least 75% of cases a high motility and good morphology of sperms were combined, and also low motility and poor morphology.

It is hoped that in 1946 the meeting may be held in London.

Correspondence

Education in Safe Milk

Sir,—The vigorous speeches at the recent Representative Meeting and your own impressive leader (Aug. 4, p. 160) may well be welcomed by senior members of the profession who for a number of years have endeavoured to secure for the community a milk supply safe from the risks of tuberculosis and other infections. In this respect the British Medical Association, together with other organizations, has met the responsibility which falls on the profession as guardian of the public health. Nevertheless, it has to be admitted that successive Governments have not been impressed, not at least to the point of action, and that the public generally is largely uninformed and unalarmed. May it not be well to supplement corporate votes and resolutions by the teaching influences of the individual doctor? Given, say, 20,000 doctors each using his opportunities to impress upon his patients, and especially on the parents and guardians of children, the dangers of raw milk and the protective values of pasteurization, there might reasonably be expected a demand for safe milk which the commercial interests concerned would find it profitable to supply. Such an educational policy would be an exercise in the practice of preventive medicine and a further contribution to the discharge of an admitted responsibility. There are interests actively opposed to the pasteurization of milk, and to meet these the Government needs not only the opinions of experts but also the support of public opinion. And in the development of that support the individual doctor has his opportunity.—I am, etc.,

Hove. C. O. **Hawthorne.**

Milk Still Unsafe

Sir,—"We are left to speculate what the drag on the wheel may be—departmental lethargy or the opposition of agricultural interests." To this quotation from your leading article (Aug. 4, p. 160) might have been added the lack of pressure and determination of the medical profession to see this job through when it had started on it. It is "the little more" that is needed, and I venture to hope that Mr. Lawrence Abel's renewal of the attack and the prominence given to it in your able leader are an earnest that the scandal of our impure milk supply will be ended by the adequate pasteurization of all milk intended for human consumption. Personally I doubt the wisdom of exempting T.T. milk or "accredited" milk from a single herd. Typhoid and many other infective elements don't spare either, and the conditions of "watering" animals on some of our farms leave much to be desired.

The opposition of wontedly harassed and hard-pressed "agricultural interests" may or may not be understandable, but it is undoubtedly real. Some of these "interests" sit on the milk committees of our county councils and county borough councils, and, whilst zealots for "pure milk," are not backward in indicating opposition to what they regard as "further burdens on the industry." I remember once addressing the members of one of these committees, of which I myself was a member, about the importance of an abundant and pure water supply for cattle on our farms, and the necessity for fencing off all muddy and contaminated sources from ditches and swamps to which cattle often has ready access. I was giving them a lurid example close by in their own area, where a little streamlet draining down from the hills through village and hamlet was dammed up here and there adjoining fields where cattle was grazing. It was no unknown sight to see the housewife emptying an occasional pail into this stream as it passed her door, and into the dammed-up pools the cows would stray to water, and "stale," and stamp the whole filthy area into a grim and revolting quagmire. I was suggesting that these "cesspools" (for they were nothing else) should be fenced off from cattle access and the "possibilities" arising therefrom through drinking and the soiling of pendulous and rarely washed udders. I expect, however, I was manifesting my innocence and ignorance of the practical problems affecting the safe milk campaign, for just as I was winding up my remarks a smile broke over the faces of members at some interjected witticism which I had evidently evoked but was unable to catch. I resumed my seat in an atmosphere of hilarity and mirth. So far as I am aware, however, *nothing has been done.*

My own limited experience leads me to believe that it would be unwise to make any exception to a general pasteurization order except in the case of supplies intended for "processing" at high temperatures. If I may be permitted I should like to reiterate and emphasize your own remarks on America's attitude to this important question: "American troops in this country have not been allowed to drink milk unless it was *both from tuberculin-tested herds and had been pasteurized*; yet, so far from insisting on the double protection, we do not even make universal the simpler of the two expedients." I commend America's realism and thoroughness and your comment. The medical profession must maintain a crescendo of pressure and determination to get pasteurization established. But the order must be a general one and emanate from central authority.—I am, etc.,

Bournemouth. J. ROSS MACMAHON.

SIR,—Having just spent a fortnight on a farm which runs a herd of tuberculin-tested Jerseys I am acutely conscious of the delight of pure milk as compared with pasteurized milk. You say in your leading article (Aug. 4, p. 160) that it would cost £10 million a year to pasteurize all milk and deprive us for ever of the joy of tasting pure milk. £10 million annually is the equivalent of £400 million at 2½%. Would it not be more economical to pay £400 million once so as to enjoy pure milk in perpetuity, than to spend £10 million annually so as to suffer from pasteurized milk in perpetuity?—I am, etc.,

Petersfield. RICHARD HOPE.

Weight Reduction by Dieting

SIR,—The letter on weight reduction by dieting by "Apollonian" (July 28, p. 136) interested me very much. Hitherto we have, as a profession, taken little note of the effect of diet on the general well-being of our patients. One only requires to study the diets given in hospitals all over the country to find proof of that. In the past we have been too ready to rely on some specific medicine which would affect the organ or particular part of the body showing signs of disease, rather than consider the body as a whole. "Apollonian" opens up a new field for study and research. It would be interesting to know what changes take place in the human body during a prolonged fast. Does it alter the *p*H of the blood and the urine, and what changes take place in the intestinal flora? I have heard it stated that at the end of the long winter period the hibernating bear has sterile intestinal content, and that its flesh is sweeter to taste. Does this mean that a cleansing process has been going on during the fasting period?

I have watched many patients undergoing fasts for short periods of a few days to longer periods of 30 and 40 days. In no instance were there any adverse signs or symptoms during the fasting period other than a slight feeling of lassitude or a headache and loss of weight. Usually as the fast continued the feeling of well-being increased. Like "Apollonian" I have often experimented on myself, but regret that I had not the time and facilities to check up all the changes taking place in my body during the fasting period. Just recently I completed an 8-days fast while continuing my usual activities, which are not less than most doctors'. Here are a few changes that took place.

	Before Fast	After 8-days Fast
Weight (naked)	10st. 7 lb.	9 st. 11 lb.
Chest	36 in.	35 in.
Waist	33 in.	31 in.
At umbilicus	37 in.	33½ in.
Thigh	22 in.	20 in.
Calf	14 in.	13½ in.
Biceps	11 in.	10 in.

I may say it had a wonderfully rejuvenating effect on me and cleared up a few odd pains that I had. "Apollonian" says he took certain vitamins in tablet form, also an alkaline mixture three times daily and some sweetened non-alcoholic drinks. I took no vitamins or alkaline mixtures during my fast and only an occasional sip of water. My bowel moved at the beginning, but once or twice during the fast I had a colonic lavage. This may not have been necessary. It is well known that our seamen who have had to take to the boats after a shipwreck have no bowel movement even when 2 or 3 weeks on the open sea.

Scientific dieting may not be the most pleasant medicine, but in a few stubborn cases it is very effective. The patient may be put on an absolute fast for days or given fruit or vegetable juices, or drinks mixed with fruit juice and milk. If carefully watched there is never any danger.—I am, etc.,

Bishopbriggs, Glasgow. JOHN WINNING.

SIR,—I read "Apollonian's" letter on weight reduction by dieting with great interest, as I have myself fasted, but not with the same happy result.

After six days of fasting and working I was delighted to find that I had lost 16 lb., as I was over-weight. On the seventh day I developed acute gout in my left ankle. I found out too late that if one fasts, while it is not necessary to go to bed, it is essential that one should not work and should have a definite routine of mild exercise and plenty of rest. It is also essential that if one fasts one should also eliminate, as when the liver finds that it is not necessary to do its normal work it proceeds to rid itself of accumulated waste products. In "Apollonian's" case he relied on taking copious fluids, thus putting the chief work of elimination on the renal system. He should have had an enema on alternate days and a Plombières treatment at least once a week, sweat baths on alternate days, and massage on alternate days to assist elimination. In my own case I think that any waste products went to my left ankle, which was an old football injury, but which had given me no trouble for many years. I think it is much wiser for patients who wish to reduce their weight by fasting to go into a clinic which specializes in these things or at any rate to a spa where they can have eliminative treatment. I am all in favour of scientific fasting, not only for reduction of weight but for other diseases in which a septic focus cannot be found, but it must be scientific.

I was so ashamed of my obstinacy in thinking that I could fast and work, contrary to the advice of my friends, so I continued to work instead of going into a nursing home to rehabilitate myself. As a result I have had chronic rheumatism ever since. I have never put on weight again, and it would seem that my diet, which previously over-nourished me, now turns to uric acid, and it would also seem that once one's chemistry has been upset it is impossible to put it right again.

It would be interesting if "Apollonian" would write again and tell us how he is a month after his fast, and what type of diet he took to begin with before he returned to a normal diet, and when his bowels commenced to function again. I think he should have signed himself "Hercules" and not "Apollonian."—I am, etc.,

"CASSIUS."

Aspiration Test in Diagnosis of Breast Tumours

SIR,—I would be grateful for a little space in your *Journal* to emphasize the value of the aspiration test in the diagnosis of breast tumours. It is now generally agreed that every breast tumour must be regarded as a carcinoma until it is proved innocent, and it is because of this accepted view that an ever-increasing number of cases are being seen for early diagnosis.

A tense cyst situated in an area of chronic mastitis so closely simulates a carcinoma that one is often tempted to advise radical mastectomy without a preliminary incision of the tumour. Few surgeons would not confess to having performed a carefully planned radical mammectomy for an apparently obvious carcinoma, which upon subsequent incision and section proved to be an innocent cyst. A tense cyst is easily palpable with the flat of the hand, and as it finds its origin in an area of mastitis it imparts an impression of undue fixation in the surrounding breast tissue. When other confirmatory signs are lacking, one is justified in attempting to aspirate the swelling with a fine-bore needle. This simple procedure in a few seconds can banish any element of doubt concerning a lump in the breast. A few c.cm. of turbid fluid are withdrawn, the tumour vanishes, and only a depression remains in an area of mastitis, which can no longer be appreciated with the flat of the hand. Should the tumour be solid, the needle is felt to pass through it with increased resistance, whereas it pierces a cyst wall with characteristic ease and suddenness. The patient is therefore saved the inconvenience of a biopsy, and can be kept under regular observation.

It can be argued that the trauma of needling may cause a carcinoma to "metastasize" more readily. This cannot be denied, but the degree of tissue disturbance must be minimal, and therefore probably is no more harmful than a series of determined palpations which a mammary tumour of doubtful identity usually suffers.—I am, etc.,

Chelmsford. M. D. SHEPPARD.

March Fracture

SIR,—Mr. Ian D. Kitchin (July 14, p. 64) has commented on the frequency of march fractures and their treatment. I am in entire agreement with him that these fractures should be relieved from weight-bearing in their acute phase. It is, however, worth mentioning that the acuteness varies considerably and the length of treatment can be modified accordingly. Radiological confirmation also depends on the severity of the lesion. The most severe cases do not show any signs of periosteal involvement under 5 to 7 days, and in the less acute cases this may be prolonged to 10 or even 14 days. Extremely mild cases are sometimes seen which have never been reported to the M.O. Such a case would give a history of slight pain in the foot a few weeks previously which gradually disappeared. Although this is not common, it shows that resolution may occur without any interruption of training. This is of interest, because the length and type of treatment can depend on the severity of each individual case. Over 200 cases have been observed, and at one time every case was put into a walking plaster for a month. This was discontinued when it was found that treatment was being unnecessarily prolonged. After a month in plaster, at least two additional weeks are required to mobilize and strengthen the foot muscles before full training can be recommended. Plasters may be required for the most acute cases, but the treatment of a case of average severity can be shortened by the use of a felt metatarsal pad. It is necessary to insist that Army boots are worn, because the thick and unbending sole forms a most effective splint. After one week most men are able to walk about in boots with comfort. Non-weight-bearing exercises are then commenced and training is very gradually introduced. Jumping and running should be forbidden for a month, and at the end of this time full training can be resumed. This method has advantages so long as it is used with discretion, and it certainly shortens the period of inactivity. It is, however, useless to keep a man on infantry training while he still has a painful foot, and march fractures should always be given a period of rest to allow the acute phase to subside.

Although the second or third metatarsals are the most commonly affected, fractures do occur less frequently in the fourth and fifth. It is possible for two metatarsals to be involved at the same time, and rarely three metatarsals may show march fractures. The aetiology is still obscure. Blair Hartly believes that they are analogous to the stress fractures of metals. It is possible that some interference with calcium metabolism predisposes to this condition.

In an article now in the medical press I have shown that these fractures are very frequently found in men who have adolescent kyphosis or signs of old rickets.—I am, etc.,

Lisburn, Co. Antrim. R. W. WINDLE, Major, R.A.M.C.

Emergency Treatment of Fractured Femur with Shortening

SIR,—I have just received the *Journal* of July 7 and am amazed at Fl. Lieut. J. Noel-Jackson's article on a case of fractured femur (p. 16). Evidently pride in the ingenious products of his blacksmith has blinded him to the gross faults in surgical technique which he displays. Even without the assistance of *x* rays he should have been able to tell from local tenderness, bruising, etc., that the fracture was in the neighbourhood of the great trochanter, and therefore the correct first-aid treatment was abduction in a plaster spica. If, however, he believed the fracture to be in the mid-shaft his first effort with a Thomas splint and skin traction was correct. This proved uncomfortable, probably through errors in applying the strapping, so he manufactures that abomination an ice-tong calliper. Under the conditions of lack of asepsis that no doubt prevailed, this implement is as dangerous as a Steinmann pin would have been and much less efficient. Then Fl. Lieut. Noel-Jackson finds that he is unable to use his callipers with a Thomas splint, so his patient blacksmith has to make a Braun frame, and with it all hope of immobilizing a pertrochanteric fracture disappears.

It was then decided to apply a plaster, so a board with a perineal post is slipped under the unfortunate patient, and the whole paraphernalia hoisted up on the delightful machine which is illustrated. I note that when the Braun frame was removed the knee became extended, thus displacing the fracture. Then plaster was applied. If your correspondent means a plaster spica I cannot see how he passed the bandage between the patient's back and the board; while if it extended only to the groin he might just as well have put plaster on the penis for all the effect it had on the fracture. I am not surprised that union was poor a few weeks later. I am surprised there was any union at all.

Fl. Lieut. Noel-Jackson is now entitled to ask me, "Well, what would you have done?" Here is my suggestion: a roller towel or domette bandage round the perineum and fastened to a hook behind the patient's head; a pudding bowl under his sacrum; pentothal anaesthesia if available, and failing this a full dose of morphine. The surgeon applies manual traction to the fractured limb for 5 minutes, abducting and internally rotating it, while an assistant pulls on the sound leg. When shortening is corrected a second assistant takes over the limb and maintains the position while the surgeon applies a plaster spica extending from the lower ribs of the opposite side to at least below the knee of the fractured leg and preferably to the sole of the foot. In this state a patient can lie comfortably till the snow has been cleared and he can be transported to hospital. Such a plaster if left on for months might cause hypostatic pneumonia, but for a few days it is quite safe. The final treatment in hospital would probably be nailing or Roger Anderson's "well-leg" traction. I have recently used the above method with perfect success, although I had access to pins, wires, Braun splints, and all the other ironmongery of the trade.—I am, etc.,

Messina. J. S. JOLY, Surg. Lieut., R.N.V.R.

Hereditary Transmission of Dupuytren's Contracture

SIR,—In the copy of the *Journal* of May 26, just arrived, there is on page 741 an annotation on clinical effects of vibrating tools, wherein your annotator tells us that "Dupuytren's contracture and ulnar paresis can undoubtedly result from the pressure of these tools on the palm of the hand." A few months ago the writer of an answer in your "Any Questions ?" column (March 10, p. 354), with just as little hesitation, assumed that Dupuytren's contracture was due to trauma.

Now that is what Dupuytren imagined when he wrote about the condition in 1831. It is said that he observed it in his coachman, and he thought it developed through wielding the whip. With this authority to start it, the explanation was copied into the textbooks one after another, and this has gone on for the past 114 years or thereabouts. Mouldy and outdated, it is still there. Some angry person has said that it takes 30 years to get anything into the textbooks and 100 years to get it out, but, of course, people exaggerate. When this particular bit of misleading authoritarianism will fade out of our textbooks it would be rash to anticipate, but the contributors to our periodical literature could be usefully employed in getting on a little faster than the textbooks.

Since 1900, when Mendel's work became known, those who have studied such matters have seen reason to be extremely sceptical or, rather, to deny categorically that acquired characters are passed on by inheritance. Also, since Dupuytren's time there have appeared many papers about the condition bearing his name, some of them in the *British Medical Journal*, and many of them have recorded examples of its hereditary transmission. I confess that I have written about it myself. Your readers may not have easy access to a file of the *Medical Journal of Australia*. There, in the issue of Aug. 19, 1944 (pp. 177–82) they could find a large array of familial cases, included in 8 families. I quoted one family record, contributed by E. S. Stokes, which presented one line in which the condition was passed on through an unaffected daughter from grandfather to grandson. In a second line from the same family stock it was passed on from a great-grandfather through an unaffected daughter, and then through her unaffected son, to a great-grandson. In the issue of the same *Journal* of Oct. 21, 1944 (p. 442), Marie Brown added a case in which it passed from a grandfather through his unaffected daughter to a grandson.

And now may I be allowed to quote from the summary of my paper.

> "The still current view that Dupuytren's contracture is due to trauma or toxaemia is criticized. Such theories are found to depend on conjecture, a tacitly assumed major premiss, without attempt at proof. This assumption is that the condition present is an ordinary chronic fibrositis, and that, as such, it can be caused by agencies such as trauma or toxaemia. It is pointed out that if Dupuytren's contracture can be caused in this way, it provides an instance of the origination of a condition which is passed on to descendants, preserving its pattern. This presents a dilemma which is intolerable, and the theory is decisively rejected.' The more likely alternative is that all cases of Dupuytren's contracture are familial, and would always be found so if the descent and complete family history were accurately known. It is suggested that the great preponderance of males, which extends to all cases, familial or supposedly non-familial, is capable of a Mendelian explanation."

—I am, etc.,

Sydney, N.S.W. C. E. CORLETTE.

Effects of Tobacco Smoking on Health

SIR,—I read Dr. Lennox Johnston's letter (July 21, p. 98) on the effects of tobacco smoking on health with the greatest interest, and with relief. At last tobaccoism, this tacitly accepted disease, with its many symptoms and serious effect on mortality, has been challenged. Dr. Johnston exposes the "tobacco taboo," which has such a stranglehold on the situation. Why have we tolerated this? Is there a real lack of moral courage in the medical profession to-day? Is it a question of "Physisian, heal thyself"?

As a psychiatrist most of my patients are depressed, many suffering from various forms of anxiety neurosis. In far too many cases I have been told: "My doctor told me to smoke; he said it would soothe my nerves." The reverse has generally resulted; and the patient has become still more depressed and "nervy."

Of course the heavy smoker's cough is a universal symptom that we all meet with. I know one heavy smoker who, whenever he gets even a trifling cold in the head, develops a violent cough which lasts at least a couple of months. On the last occasion his wife said she was kept awake every night, once until 3 a.m., by her husband's "terrible cough." This must happen in thousands of homes, with consequent loss of sleep and efficiency. A lady who has had pneumonia several times is a chain smoker. She has frequent paroxysms of coughing that are distressing to witness. I was told that even in her sleep she wakes her family through this. Yet she maintains that her doctor has never even asked her to smoke less, or suggested that she should give it up.

You have only to request young men or women not to smoke in a non-smoking railway compartment (most older people will courteously comply) to receive the most vitriolic insults. Last week I was told by two soldiers that they only wished they had me in Germany with a tommy-gun, merely because I asked them not to smoke in a non-smoking compartment on a journey of just over an hour. The idea that cigarettes are an absolute necessity for all the Forces all the time shows how ingrained tobaccoism has become in the nation.

What is the cause of all this? In my opinion two separate fears and "big business." (1) Fear—i.e., lack of moral courage —of not being thought "modern." Considering that the modern world has exceeded all previous records in cruelty, beastliness, and destruction the actual achievements of modern life are, to say the least, doubtful. (2) Fear of having to face and deal with life without the dulling (so-called soothing) effect of smoking. (3) Immense financial interests are involved, and the sale of tobacco is pushed with all the skill and subtlety of psychology applied to business. I consider this mass suggestion in advertising one of the great evils of our time; its constant pressure in direct and indirect ways has a huge cumulative effect; and we must remember that with the end of the war in Europe it will increase. The result of this in the sale of patent medicines is bad enough (especially to my patients), but the harm done by advertisements of alcohol and tobacco is far more widespread and serious.

Smoking has immensely increased during the war—by 34% between 1937 and 1944, as Dr. Johnston points out—especially among women. We can only discover later the full effect of this, especially on the newborn child, on small children as well as older ones, and on the home. But I believe that smoking, this "means of administering a drug of addiction," is one of the causes of the increase in nervous illness. Our nation is numerically small, yet our position in the world is vital and we have an amazingly important mission to fulfil in the future. It is our duty to protect and promote the health of this nation in every way. The medical profession has done a very great deal to improve it, even during the difficult years of war. Is it not now time to consider honestly this insidious and increasing disease of tobacco smoking, and take courageous and energetic steps to overcome it?—I am, etc.,

London, S.W.1. SYBIL TREMELLEN.

Identification of Gas Cylinders

SIR,—Dr. A. Owen-Flood (April 14, p. 535) states that on the Coxeter-Mushin apparatus fitted with "Romac clips" it is not possible to connect the nitrous oxide or carbon dioxide cylinders to the oxygen flowmeter. There also appears to be a popular idea that the couplings used on this apparatus and on the new Boyle's table are non-interchangeable and foolproof. It is necessary to offer a warning against this supposition. In actual fact it may be possible to apply any of these clips to a smaller-sized outlet than the one for which they are designed, a perfectly satisfactory and gas-tight attachment being obtained by depressing the fastening lever in the reverse direction to the usual. This is a method of obtaining a tighter fit from the clip which we have been using on our high-pressure pipe-line for the past two years whenever the clips became worn.

On a new Coxeter-Mushin table which was placed in my charge recently direct from the manufacturers not all the clips are loose enough to stand misplacement; but it is possible to couple the nitrous oxide tubing to the oxygen cylinder, the oxygen tubing to the carbon dioxide cylinder, the nitrous oxide tubing to the oxygen or the carbon dioxide flowmeters, and the oxygen tubing to the carbon dioxide flowmeter. It is not possible to connect the clips to fittings larger than those for which they are intended; this leaves a safeguard in that a misplaced clip leaves its proper fitting uncovered and the attendant may notice this—except on machines equipped for a pipe-line where one of the two additional clips might be utilized or when the machine is not carrying its full complement of cylinders. A simpler, cheaper, safer, and more satisfactory method is to wire the rubber tubing, which lasts quite a long time, to the reducing valves, flowmeters, and any other connexions contained in the system.

I have worked both with the system where the anaesthetist does all the servicing of the machine and where he merely uses an apparatus already prepared, taking the responsibility for any mistake. I am convinced that the more or less skilled attendant employed in the latter case is not in the least likely to be deterred either by the improbability or by the difficulty of the mistake he is able to make. There appear to be only two solutions to the problem of avoiding such accidents as the fatal administration of nitrous oxide in the place of oxygen, as reported in the daily press recently. The first, the servicing and use of machines only by skilled anaesthetists, is reliable in theory. The second, the use of nothing but truly non-interchangeable connexions, either of the screw or of the male and female type, involves considerable problems, since it entails the modification of every machine and cylinder in the country.

In the meanwhile it seems a pity that the modern anaesthetic machines show so little advance in design. The introduction of permanent piping, for instance, would allow of the use of only one reducing valve of each type, and result in the reduction of the number of connexions by two-thirds. Let us hope that the improvement in the war situation and the activities of the committee now sitting on the subject will soon give us machines which will prevent this needless loss of life.—I am, etc.,

Worcester. E. F. GLEADOW.

Death Certificates

SIR,—What a profusion of literature we now receive all with the theme: "Now that the war in Europe is ended and we are no longer threatened by deaths from bombs and rockets, death from disease (heart disease kills 126,000 annually) is still with us"! Deaths from various forms of heart disease—126,000 are killed every year: how inaccurate this statement is! Practitioners know full well that with probably half the certificates they sign, giving heart disease as the cause, the actual reason for the exit was "old age," "worn out," or "B.T.S." (born too soon). But what happens if one is unwise enough to put "old age," "worn out," or "B.T.S." on the certificate? It is, of course, returned to us pointing out that these are "undesirable terms." The result is that one has to rack one's brains to think of some other cause. One probably argues with oneself that if a person has died of old age there was probably some form of "myocarditis"—hence "heart disease kills 126,000 in England and Wales in a year."—I am, etc.,

M. F. McDONNELL,
Medical Officer of Health.

Northfleet, Kent.

Hypoglycaemic Fatigue

SIR,—I have read with great interest the annotation on hypoglycaemic fatigue (June 23, p. 881). It stresses the importance of a "physiological basis of many neurotic symptoms"—functional neurotic symptoms which are often vague, not connected with any one organ. I am thinking of patients with fatigue, tremor, effort syndrome, hunger pain, giddiness and faintness, or signs of an anxiety state without a personal cause. They have in common the sweat of the palms and the axillae, tachycardia, and on clinical examination no abnormality can be detected, but on laboratory examination the following abnormalities are found: (1) phosphaturia, (2) relative or absolute hypoglycaemia, (3) changes in the electro-encephalogram.

The phosphaturia was known to exist in so-called nervous or functional patients, some of whom were found to have hypoglycaemia, and when they had the hypoglycaemia they had phosphaturia. It seems to me as if there is a direct connexion or metabolic disorder similar to the acetonuria in diabetes mellitus. The hypoglycaemia appears to be time-bound, occurring, when it occurs, almost invariably at the same time of the day or night. Whatever its cause it is a psychosomatic syndrome, which must be approached by somatic treatment. Normal fasting blood sugars do not exclude hypoglycaemia after meals; but hypoglycaemia detected once only by a reliable and efficient observer demands investigations. That the so-called neurotic element is due to an organic foundation can easily be understood from the changes seen in the E.E.G.; further from the pathological findings as published by Lawrence, Meyer, and Nevin (*Quart. J. Med.*, 1942, **11**, 181). However, these vascular changes are not specifically cerebral. They can occur anywhere in the body, producing a thrombosis or necrosis—e.g., a case of coronary thrombosis in a hypoglycaemic attack was observed by me about ten years ago in a patient aged 38.

Hypoglycaemia or glycopenia or glycogenaemia is a typical instance of an apparently functional disturbance, but really caused by an organic abnormality, and if not recognized as such may lead to serious disability where there is no need for one. Untreated the functional disturbance may lead to: (1) that a person is labelled "functional," suffering from effort syndrome, functional dyspepsia, etc., and therefore disabled and unfit for certain occupations; and (2) that he may receive psychiatric or psychological treatment where organic treatment is simple and a primary necessity—a point which is easily forgotten. Lastly, I would like to point out that in some of these cases as in many chronic diseases disability only occurs at times of stress, and is not due to or connected with these chronic diseases, which independently need medical or surgical attention.

The following are among cases of hypoglycaemia seen by me which I believe are worth mentioning; the blood sugars are given fasting, and 30, 60, 90, 120, 180, 240, and 300 minutes after 30 g. of glucose.

(1) Carcinoma of oesophagus, no secondaries, in a male: blood sugar 50 mg. per 100 c.cm. blood; then after the intervals stated above 130, 126, 52, 41, 78, 63, and 67 mg. per 100 c.cm.

(2) Malignant pyloric obstruction, no secondaries, in a female, aged 58: blood sugar 72 mg. per 100 c.cm. blood; then 62, 62, 51, 71, 67, 44, and 40 mg. per 100 c.cm.

(3) Pituitary cachexia (Simmonds's disease; see *Lancet*, 1935, **1**, 1502): blood sugar 62 mg. per 100 c.cm. blood; then 130, 80, 70, 100, 78, 60, 60 mg. per c.cm.

In a fourth case—that of a man aged 31 with inner-ear deafness and macular retinitis—the blood sugar was 83 mg. per 100 c.cm. blood, and after 30 mins. 140 mg. per 100 c.cm., after 60 mins. 120, after 90 mins. 85, after 120 mins. 90, and after 180 mins. 65. This case is of special interest as all his symptoms and signs practically cleared up on thyroid treatment—a happy result, if a somewhat unusual and unexpected one.

The treatment in most of the cases consisted in frequent feeds and plenty of carbohydrates, and atropine grain 1/100 t.d.s. by mouth seemed to be of great value to the patient, who thus found relief from his unpleasant symptoms. Barbiturates like luminal apparently aggravate the symptoms and increase the frequency of the attacks.—I am, etc.,

Highgate, N.6.

L. RAU.

"Under the Influence"

SIR,—Twenty years ago, when I began the duties of a police surgeon, defendants in such cases were willing to be tried in a Magistrates' Court, but nowadays they have become wise as to the possibility of being acquitted if the case is tried by a jury, either at the Assizes or Quarter Sessions, and in nearly every case they now elect to be tried in such a manner. In consequence the lot of police surgeons in such cases has become intolerable. The hanging about at these courts, only to have the case dismissed by a jury after cross-examinations and evidence of some witnesses who do not appear to realize what evidence on oath means, is exasperating, to say the least of it.

It has recently been my experience to certify as "under the influence of alcoholic liquor" two motor-car drivers who elected to be tried by a jury and who were in my opinion both undoubtedly intoxicated at the time of examination. In both cases the accused were defended by very well known King's Counsel, who cross-examined me very closely. In each case I was in the witness-box for nearly one hour after waiting all day to be called, in spite of my asking to have my evidence taken first. In one case defending counsel objected to my being called first, saying that he wished to call witnesses in the correct sequence of events leading up to the arrest. I was called last out of a considerable number of witnesses, in consequence of which that day's medical visits had to be carried out hurriedly and somewhat indifferently later that evening, some cases not being seen till the next day or even later. The accused obtained an acquittal in spite of the medical and general evidence of all witnesses, and in one case in spite of the fact that the judge summed up against the accused.

The crux of the matter appears to be the clause in the report of the Committee, appointed in October, 1925, by the B.M.A., on Tests for Drunkenness. This clause states: "There is no single symptom due to the consumption of alcoholic liquor which may not also be a sign of some other pathological condition." In each of the above-mentioned cases defending counsel quoted this clause word for word and put the question to me as to its validity, to which I had to admit agreement. In fact, in one case after being questioned I was politely informed, "Well, Doctor, we have reached test fifteen and he is still sober." Truly, legal jugglers can make black appear to be white.

In the *Practitioner* for April, 1945, Prof. Sydney Smith, in an article "Alcohol and Road Accidents," aptly states "that if the definition of a number of States in the U.S.A. were adopted in this country, namely: 'If the ability of a driver has been lessened in any degree by the use of intoxicating liquors, then the driver is assumed to be under the influence of intoxicating liquor'—then the problem of suitably dealing with the drinking driver would be greatly simplified." The enormous waste of time and nervous energy in attempting to help the police in such cases is utterly futile. At present the law is defeating its own ends, so far as protecting the public is concerned, for even if an individual is practically insensible from drink, I believe that under the present ruling he will still obtain an acquittal.

I have informed the chief constable of the county in which I practise that I cannot in future undertake the examination of persons so charged, and I doubt very much whether he will obtain the services of any other doctor to undertake these examinations under existing circumstances. Blood and urine examinations to ascertain the percentage of alcohol in the blood and urine respectively might be used, but these are of only relative importance, and before taking such specimens the consent of the individual must be obtained, which in all probability would not be given. The whole procedure is becoming a farce, especially in view of the enormous increase in motor traffic which may be confidently anticipated when petrol rationing comes to an end.—I am, etc.,

Alresford, Hants. C. E. MERYON.

Doctors and the Social Trend

SIR,—It may be remembered that on more than one occasion in the past I have endeavoured to emphasize the very wide nature of the present social impulse that is making itself felt in the medical profession. We, like many another institution, had for some time toyed with a plan of reform, and possibly one day such plans might have culminated in a few quite desirable changes of procedure. But to-day the motive force is not provided by a few restless consciences within our ranks. It is, as I have pointed out previously, nothing less than a world force; and the world, this country, and its medical profession require men who can direct its energy rather than spend their strength against it.

Unfortunately the life of a medical man is often much too detailed and specialized to permit a dynamic sense of his position. Many doctors (e.g., Dr. Guy Bousfield, *Supplement,* July 28, p. 18) still seem to cherish the idea that reform of the health services should be designed primarily to meet the wishes of the medical profession, and that the demands of any wider democracy upon their services should be resisted by a sort of medical "junta." And that rather unrealistic and short-sighted attitude is by no means confined to the rank and file. It would appear likely that much of our heritage has been irretrievably frittered away by those of our leaders who failed to recognize the weight of the present social avalanche. The chance to compromise with the more moderate elements has now gone, and we must face the prospect of a far more rapid evolution at the hands of a Government that cannot be expected to feel at all sympathetic with our professional interests.

At the General Election thousands of people like myself voted Conservative in the hope of preserving a stable and wise leadership at home and abroad which might smooth the action of the social upheaval on this country. It is a measure of the force of that social upheaval that such votes were nevertheless completely swamped by its influence on the poll. The electorate is no longer content with a Conservative filtrate of Socialist doctrine. The bulk of our patients now require a health service organized 100% in their interest, and no doubt will refuse to tolerate any sectional obstruction to the mandate that has been given to their leaders for this purpose. That is not to say that the design of the new health services has been removed entirely out of our hands. On the contrary, it is obvious that our co-operation will still be sought and valued. But it will have to be co-operation now and avoid all appearance of being a sort of rearguard action to enable the main body to escape with the valuables.

Obstructionist talk and writing are highly detrimental to our interests, and much public sympathy has already been forfeit in this way. The medical profession is the servant of the public in fact as well as ethical theory, and suggestions that the wishes of a majority of doctors in or out of the Services should be paramount are most harmful. Our leaders must be prepared to co-operate and sympathize with the aspirations of this Government or be prepared to give place to others who will do so. Defiance of a democratic Government by a small minority is not practical politics. The only course, therefore, is to exhibit a co-operative spirit and make a genuine endeavour to give the public the best possible chance of trying out the type of health service it elects to institute. If this Government was convinced that it had to deal with medical men imbued with that spirit it would in turn feel a much greater readiness to sympathize with their views. We may even have to face a salaried service now, but an adequate salary would go a long way towards making that supportable to its most vehement opponents. The average patient is not averse to the payment of his doctor, and may be expected to support reasonable demands for compensation or payment for any service he requires. Such things as that are not to be sacrificed lightly, and indeed any mutually constructed service will almost certainly prove to be a better thing for everyone than anything that could result from the unconditional surrender of the medical profession after a tussle with the country as a whole.

No one can now fail to discern the signs of the times. The country is possessed by an idea for the realization of which it has repudiated its greatest hero in the hour of his triumph over our enemies. The ablest leaders must march ahead of opinion. Let no one therefore suppose that by lagging behind he can obstruct the course of events, or that the medical profession can any longer defy a force that has swept Mr. Churchill aside.—I am, etc.,

Eye, Suffolk. J. SHACKLETON BAILEY.

The Special Treatment Centre

SIR,—I have read in the Parliamentary notes in the *Journal* of June 23 (p. 890) the report made by the Minister of Health upon the arrangement and working of the medical services in England in the weeks following D-Day. There is no doubt that great things were achieved and that a remarkable nation-wide organization showed that it could work well when it was required.

One of the points made by the Minister was to the effect that the opportunity was taken to put into operation a scheme to classify different types of injury, and to send those suffering from them to prearranged centres, established up and down the country, for treatment. Apparently in the conditions present at the time the arrangements proved satisfactory, and it seems certain that many of the planners in our midst will take this as an argument in favour of setting up special centres in widely separated parts of the country in peacetime for the treatment and diagnosis of certain diseases. This is a letter from one who has had the opportunity of seeing some of the effects of this form of regionalization and has suffered under it himself; it is a plea that much thought should be given to the matter before any action is taken.

Of first importance is the fact that all regionalization of medical services in the above sense must, of necessity, be largely for the convenience of the organization and not for that of the patient, no matter what safeguards are introduced. The patient would always rather be treated in his home town or home area if he cannot be left at home. If he has to go far afield to a special centre he will go unwillingly in most cases, and will want to know why the service cannot come to him. The only answer he can have is that it is more convenient for the organization. This feeling would not, of course, apply to men wounded in France for whom anywhere in England is home only later when they may find themselves retained in a special centre in a strange part of the country does their idea of "home" contract to "home town."

In the Services regionalization of this sort is running away with itself; special centres for various complaints and injuries have been instituted, and patients have often to be sent great distances to them when there are facilities for the proper treatment on the spot and the only thing lacking is the "specialist." I, myself, fractured my skull in Holyhead, my home town, and though there were adequate facilities for treatment there it was decided that I must go to Bristol, which happens to be the Naval centre for head injuries. This move was made in spite of my protests, and finally resulted in my travelling to and fro between Bristol and Holyhead to the extent of 1,300 miles in the following six weeks. I am not suggesting that I suffered any harm from this variation of the "absolute rest" treatment which I was ordered by the eminent surgeon who saw me, and who assured me that Bristol was the only place I should get it. In fact my injury was fairly trivial and I had "got away with it" before he saw me. But I do suggest that this is an instance of the organization being put before the patient, and that it showed both how bound the surgeon was by the Service, and how little he could have known of the effect his advice would have on the life of his patient within that Service. In addition I should mention that there was also the expense, which was not negligible, and the separation from my family, which, though I am normally used to that, seemed at the time to be particularly distasteful; these factors were just not considered. All these things

I foresaw and used in argument when it was proposed to send me away, but to no effect; and if I, a doctor, could not save myself, what chance, I thought, could a lay patient have?

Our latest form of regionalization has now taken continents into its scope; cases of tuberculosis arising in the Eastern Theatre are now discharged to South Africa with the excuse that the climate there is beneficial. I was under the impression that the general view held was that the English climate was as good for the Englishman suffering from phthisis as anywhere, and I fancy the real reason for this latest effort is the lack of beds and staff at home. This lack could, however, be overcome very easily if the Services undertook the treatment of their own cases instead of handing them over to others. The Services, with their powers of direction and the appeal which they have to female staff, would have little difficulty in providing for the treatment of all the patients arising within them. But, no doubt, it would be inconvenient, and it is very easy to send the patients to South Africa, where, I do not doubt, they receive the best and kindest of treatment. But this is a tragic betrayal of the patient's real interests, for to a man who has already been away from home for perhaps a matter of years the prospect of being transferred now that he is ill to a strange country for an unknown length of time and always with the possibility of his dying there is terrifying. This, together with the fact that he has little say in the matter, leads to a state of mind which is not helpful to recovery.

Of course there is another side to the matter: there will never be enough specialists to have one available everywhere, and having the few there are in special centres does make them available, on paper anyhow, to everybody. By specialist I mean, in this instance, the man who has seen so much of one disease (or group of diseases) that he can recognize it by its bark and can treat it almost with his eyes shut. But I very much doubt whether these men contribute a very great amount to the sum total of medicine, and it is by no means certain that to force patients to go and stay long distances away in order to place them under the care of these men will contribute much to the sum of human happiness, nor will it save many from the grave before their time.

At the moment the special-centre enthusiasts appear to want to embrace almost all but the most elementary medical practice, and unless we can put the brake on this enthusiasm we shall all be caught up in the net. Medicine will then lose much of its humanitarian interest, for who can be interested in the unit which must be sent here for that and there for this? In addition we shall find ourselves fearful of making this or that diagnosis which we know will mean the removal of the patient from his home and the break-up, although temporarily, of his family—that is, of course, always supposing that he will go to the centre for his disease.—I am, etc.,

GUY ROWORTH.
Surg. Lieut.-Cmdr., R.N.V.R.

Universities and Colleges

UNIVERSITY OF LONDON

John Yudkin, M.D., Ph.D., has been appointed to the University Chair of Physiology tenable at King's College of Household and Social Science as from Oct. 1.

UNIVERSITY OF GLASGOW

Leslie John Davis, M.D., F.R.C.P.Ed., senior lecturer in the Department of Medicine in the University of Edinburgh, has been appointed to the Muirhead Chair of Medicine in the University of Glasgow as from Oct. 1, in succession to Prof. A. W. Harrington, M.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on Aug. 2, with Sir Alfred Webb-Johnson, President, in the chair, a Diploma of Fellowship was granted to Raymond Alexander King. Diplomas of Membership were granted to D. A. N. Barran, A. V. G. Bibby, D. G. Evans, P. M. R. Hemphill, G. F. Jolly, R. A. J. Pearce, E. J. M. Weaver, and to the 130 successful candidates whose names were published in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Aug. 11 (p. 201); as were the names of the five successful candidates for the Diploma in Public Health. Diplomas in Medical Radiology and in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Physicians of London, as follows:

DIPLOMA IN MEDICAL RADIOLOGY.—R. A. Andrews, K. C. Falkner, R. M. Hall, T. M. Young.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—D. Ainslie, F. J. Damato, A. J. Elliot, H. C. Kodilinye, J. M. Loftus, P. J. McNicholas, L. H. G.-Moore, J. C. Mustardé, T. H. Negus, A. K. Pittman, D. Shorten, R. Vaughan-Jones.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council, held on July 28, Mr. Eardley Holland was re-elected President to take office in October next. The following officers were also elected: *Vice-Presidents:* Profs. D. Dougal and R. Marshall Allan. *Honorary Treasurer:* Mr. W. Gilliatt. *Honorary Secretary:* Mr. G. F. Gibberd. *Honorary Librarian:* Mr. F. W. Roques. *Honorary Curator of Museum:* Mr. A. W. Bourne.

The following candidates were elected to the Membership: T. M. Barnett, A. Buchan, Daphne Wai Chan Chun, Aileen M. Dickins, E. D. Y. Grasby, M. W. Hemans, Ursula M. Lister, Agnes M. D. Milne, Abd-El-Salem M. El-Minabbawy, K. Mitra, Joan P. Moignard, P. Raj, W. B. Shute, Beatrice M. Smyth, J. M. Thomson.

Medico-Legal

A SEAMAN'S RIGHT TO TREATMENT

If a merchant seaman reasonably believes his health is endangered by illness for which he can only be properly treated ashore, he may go ashore for the treatment even in disobedience of his captain's orders.

An assistant cook in a merchant steamer carrying troops complained to the ship's doctor of spasm in the right thigh muscles. About a fortnight later he complained of pain in one ear. By the time the ship reached Durban three months later both complaints had become worse and he was dissatisfied with the treatment given by the ship's doctor. The man went ashore and consulted of his own accord the port health officer, who sent him to two private doctors, one for his leg and the other for his ear. He also signed a letter to the captain of the ship, but this never reached the captain. Both the private doctors sent the man to a radiologist. He obtained from the ship's agents an authority to be radiographed; copies of the radiologist's reports were sent to the ship's agents and handed by them to the captain, who promptly started inquiries. The otologist, according to the man's statement later, said he must go to hospital for immediate operation, but that he must obtain a note from the ship's doctor allowing this to be done. When the man told the ship's doctor of this, the doctor, who had authorized neither the *x*-ray examination nor the consultation with the otologist, was not satisfied. He met the man at the otologist's surgery, and after a consultation the otologist told the man that the operation could wait until the ship returned to Liverpool. The man was not satisfied with this opinion and went back to the port medical officer, who also was not satisfied and sent the man to a third doctor. This doctor found the man definitely ill and in need of urgent attention to prevent infection spreading from the mastoid to the brain. He arranged for the man to see him next day so that he could make arrangements for his admission to hospital. Next day, however, the captain sent for the man and, after inquiry, ordered him to return to duty pending investigation. The man retorted that he proposed to go ashore and that the captain could not keep him on board. Shortly afterwards he went ashore, and was duly operated on and discharged about ten days later, certified as fit to travel but not to work. He did not inform anyone aboard the ship that he was in hospital; the hospital informed the ship's agents, but the ship had by then sailed. The captain detained the man's effects which he had left aboard the ship, and entered in the ship's log a statement that the man had deserted the ship at Durban.

When the man returned to England he sued the owners of the ship for a declaration that he was not a deserter, for the return of his belongings or their value, for wages, for breach of statutory duty to obtain a certificate from the shipping master entitling the captain to leave the man behind, and for libel. Mr. Justice Lynskey said[1] that to commit desertion a seaman must completely abandon his duty without justification. He took the view that the man, on the advice of the third doctor, thought an operation was imperative and delay might be fatal. He was therefore justified in taking the necessary treatment and not returning to his ship. Both the captain and the purser sent in evidence that if they had known he was in hospital they would have paid him off and not treated him as a deserter. A deserter forfeits wages and his belongings which he leaves on board, but this man, not being a deserter, was entitled to the return of his effects or £140 (their estimated value), to £20 general damages, and to his agreed wages up to the date he went ashore.

---

[1] Moore v. Canadian Pacific Steamship Co., (1945) 1 All E.R. 128.

Concerning the breach of statutory duty, the Merchant Shipping Act, 1906, forbids a master of a British ship to leave a seaman behind at any place abroad unless he previously obtains the certificate of the proper authority stating the cause. The captain agreed that he did not obtain such a certificate, and said that in practice this provision is ignored because no one knows whether a man is a deserter or not until the ship has sailed, and to obtain a certificate would mean holding the ship up for hours, if not longer. The judge found that the section imposes an absolute statutory duty which can only be altered by Parliament; but as the man had already been fully compensated he merely awarded under this head nominal damages of 1s. On the question of libel, no doubt the words written in the log were defamatory, but they were written and published on a privileged occasion. Under the Merchant Shipping Act, 1894, a master must make entries in the log, and if he leaves a man behind he must state whether the cause is desertion, inability to proceed to sea, or disappearance. The judge was satisfied that the captain had received no information from the hospital, the ship's agents, the purser, or the doctor; he only knew that the man had had two *x*-ray photographs taken and had defied his orders to remain on board and had not come back; he had made the entries in his log in good faith and the firm belief that they were true. The man therefore failed in his claim for libel and had to set off its costs against those paid by the company on his successful claims.

Obituary

LADY BARRETT, C.H., C.B.E., M.D., M.S.

Lady Barrett, consulting obstetric and gynaecological surgeon to the Royal Free Hospital, died at the age of 78 on Aug. 7. She was the widow of Sir William Barrett, F.R.S.

Florence Elizabeth Perry was born in Bristol in 1867, and, after being educated privately, decided in her early teens to take up a medical career. She studied at University College, Bristol, and the Royal Free Hospital, London. After matriculating at London University in 1893, she took her B.Sc. in 1895. She qualified in 1900, took the M.S. in 1904, and the M.D. two years later. At the Royal Free she acted as assistant anaesthetist, ophthalmic assistant, house-surgeon, clinical pathologist and assistant pathologist, surgical and gynaecological registrar with charge of the *x*-ray department, and clinical gynaecological assistant and anaesthetist. In 1908 she was appointed assistant physician for diseases of women, and from 1913–21 was lecturer in midwifery. Lady Barrett was also consulting obstetric surgeon to the Mothers' Hospital at Clapton, and honorary surgeon to the Marie Curie Hospital; she was Dean and later President of the London School of Medicine for Women. She wrote extensively on her specialty, including such subjects as "A Plea for the Feeding of Nursing Mothers as a Means of Preventing the Waste and Maiming of Child Life" and "Conception Control." This most distinguished medical woman served on a large number of committees concerned with social problems and the part played in them by women. Before the last war she was most active in starting voluntary centres in London for the feeding of expectant mothers and children.

Sir William Barrett, whom she married in 1916, was her second husband, and Lady Barrett shared with him his great interest in psychic research; after his death she in part published, in the book entitled *Personality Survives Death,* the record of sittings held with Mrs. Leonard.

Lady Barrett played an active part in the work of the B.M.A., being vice-president of the Section of Obstetrics and Gynaecology at the Annual Meeting at Newcastle-upon-Tyne in 1921, and president of the Section at the Bath Meeting in 1925. She served on the Committee on Causation of Puerperal Morbidity and Mortality in 1927–8, and also on the Parliamentary Subcommittee in 1921–7.

Dame LOUISE McILROY writes:—

Lady Barrett's death will be mourned by a large circle of friends and by those who were associated with her professional work. She had the gift of making and keeping friendships, owing to her loyalty and her charming personality. This gifted woman was a shining example to all medical women, as she combined delightful feminine attributes with those of a skilled surgeon and expert organizer in all matters pertaining to medical education. With the help of Sir George Newman, she was mainly instrumental in obtaining the obstetric unit for the Royal Free Hospital. She held the opinion that a thorough knowledge of obstetrics should be the basis of general practice as well as that of the specialist. She acted as consultant to the unit, and her relationship with the staff was always of the most harmonious nature. She freely gave advice from her wide experience not only of medical problems but of administration. As Dean of the London School of Medicine for Women her help was always available for the benefit of the students, and she gave her sympathetic advice in difficulties of study and the choice of future careers. Perhaps one of Lady Barrett's outstanding characteristics was her great courage in expressing her opinions as to what was just and right. As a distinguished speaker she was much sought after on platforms where discussions took place concerning the interests and health of women and children. She had a long vision of what should be of benefit in the way of public health reforms. She had a great sense of humour, and a happy infectious smile when amused. Her home life with her husband, Sir William Barrett, a distinguished physicist, was of the happiest. With him she studied spiritualism, and in quiet talks in their home one was given a privileged insight into a world different from that of everyday medical life. Theories were expounded by those possessed of deep scientific knowledge. Faiths and beliefs were discussed with an interest which was profound. Scientists, approaching the subject with a broad outlook, cleared up and displaced fallacies. Lady Barrett was a perfect hostess and loved entertaining her friends. She kept in touch with medical women's interests abroad, and she attended international congresses of medical women, where we were all very proud to feel that we had such a distinguished representative and charming speaker. She was always keen on any effort for the furtherance of knowledge of the cause and cure of cancer, and was a valuable member of the staff of the Marie Curie Hospital. Lady Barrett has been a shining example to all medical women on account of her good work and precious comradeship. We say farewell to her with sorrow in our hearts.

SIR THOMAS JONES, M.R.C.S., L.R.C.P.

Sir Thomas Jones, chairman of the Anglesey Education Committee, has died at the age of 74. He was born in 1870 at Llanddeusant, Anglesey, and was educated at the Liverpool Institute and Queen's College, Manchester. After qualifying M.R.C.S., L.R.C.P., and L.S.A. in 1896 he settled down in practice in Amlwch. He was subsequently medical officer of health for Twrcelyn R.D.C. and Amlwch U.D. Sir Thomas Jones was always interested in public work, and had been a member of the Anglesey County Council since 1902; he was chairman from 1913–15, and was later elected Alderman. Since 1919 he had been chairman of the Education Committee, and was active in advocating the provision of hot milk and meals in schools. He was a member of the Council of the Welsh National Memorial Association from its foundation, and from 1911 had been a member of the committee of the North Wales Mental Hospital, and chairman since 1938. He was also chairman of the Mental Hospitals Association in 1942–3, being the first Welshman to occupy the post.

In spite of his numerous public appointments, Sir Thomas Jones had an exceptionally large practice, and will be greatly missed by a wide circle of friends and patients in the island county. He joined the B.M.A. shortly after qualification, and was at one time chairman of the North Caernarvonshire and Anglesey Division; he was president of the North Wales Branch in 1935 and 1936.

Dr. WILLIAM PORTER, who died on June 10, was the senior doctor in active practice in North-East Ulster; he had been in general practice in Portrush, his native town, for over 45 years. He qualified M.B. at the old Royal University of Ireland in 1897, and M.D. in 1908. He was a trustee of Coleraine Cottage Hospital, where he did a good deal of surgery, and was M.O.H. for Portrush and medical officer of the Dispensary. He was often called in by his colleagues over a wide area to give a second opinion, and he was the "doctors' doctor" in his district, many of them seeking his advice on their own health and that of their families. Always an active member of the B.M.A., which he joined in 1900, he was president of the Ulster Branch in 1927–8, secretary of the Ballymoney Division from 1922 to 1927, and chairman of the Division in 1927–8. Yachting was his main recreation, and for many years he spent his holidays cruising round the Scottish Coast. He was keenly interested in the work of the R.N.L.I., and once during the last war he inspired a volunteer crew of the local lifeboat by putting out to sea on an exceptionally rough night; a fierce gale was blowing, and conditions were so bad that many considered it unsafe for the boat to leave harbour. He is survived by his widow, a daughter of the late Dr. Johnston, of Belfast, one daughter, and two sons—Major Robert J. Porter, R.A.M.C., formerly attached to the London Hospital, and Mr. Hector Porter, who practises in Edinburgh.

Capt. DAVID IRVING ANDERSON, O.B.E., R.A.M.C., who died on July 25, was born on May 20, 1881, and received his medical education at the University of Edinburgh, where he graduated M.B., Ch.B. in 1904, taking the certificate in tropical medicine in the same year. After holding the post of clinical assistant in the eye department of the Prince of Wales's General Hospital, Tottenham, he went to Malaya, where he was surgeon to the Johore State and Lower Perak Planters' Association. He returned for service in the R.A.M.C. in the war of 1914–18, attaining the rank of major, and was appointed O.B.E. in 1919. After the war he practised at Ripley, Derbyshire; Pontrilas, near Hereford; Hoddesdon, Herts (from 1920 to 1931, being honorary secretary of the East Herts Division of the B.M.A. from 1928 to 1931); and finally at Ross, Herefordshire, becoming medical officer under the county council and honorary physician to the local cottage hospital. He was employed as a civilian medical practitioner at Hereford Barracks when war in Europe again broke out in September, 1939, and in June, 1940, he was granted a temporary commission as lieutenant in the R.A.M.C., although then 59 years of age, becoming captain a year later. In 1942 he was transferred to the unemployed list.

Dr. C. D. FITCH, who died at his home at Chaddesley Corbett on July 19 at the age of 81, had, like his father before him, practised at Chaddesley for 40 years. Educated at Aldenham School, Herts, and at Queen's College, Birmingham, Charles Dennis Fitch qualified M.R.C.S., L.S.A. in 1885, afterwards becoming obstetric and ophthalmic house-surgeon at Queen's Hospital, Birmingham. He was fond of a number of outdoor pursuits, being a keen gardener, a sound cricketer, an ardent shot, and an acute observer of Nature, especially of bird life. But his greatest pleasure was in hunting and in point-to-point fixtures; he was a follower of the Worcestershire hounds and was a familiar figure at all horse events in the county for many years. He played a large part in village activities throughout his life and was widely respected. He was a churchwarden, a bellringer, and a trustee to the endowed schools, the Foresters, and the almshouses. He had been a member of the B.M.A. for 39 years, and in 1922 was chairman of the Worcester Division. He was a member of the Kidderminster Medical Society. Dr. Fitch retired in 1928. He leaves a son and daughter.

The Services

Temp. Surg. Lieut. A. G. M. Wilson, R.N.V.R., has been mentioned in dispatches posthumously for gallantry and outstanding devotion to duty while serving in one of H.M. ships in escorting convoys to and from North Russia.

Capt. J. A. Peters, R.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services in the field.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in North-West Europe: Major-Gen. E. Phillips, C.B., C.B.E., D.S.O., M.C., and Col. J. W. C. Stubbs, D.S.O., M.C., late R.A.M.C.; Cols. (Temp.) A. T. B. Dickson, O.B.E., T.D., C. Helm, D.S.O., O.B.E., M.C., J. P. J. Jenkins, T.D., and A. R. Oram, M.C.; Lieut.-Cols. (Temp.) C. Bainbridge, A. Cowie, M. H. Evans, M.B.E., R. Evans, F. F. Hellier, E. H. P. Lassen, D. J. MacMyn, T.D., G. A. G. Mitchell, and R. E. Tunbridge, O.B.E.; Majors (Temp.) R. Barraclough, J. Bleakley, J. A. C. Burridge, G. B. Carter, N. J. Crawford, H. B. L. Dixon, C. M. Elliott, W. Halliday, K. N. A. Herdman, P. W. Hunt, W. F. Mair, D. D. Maitland, N. H. Martin, D. I. McCallum, M.C., R. M. McGregor, D. J. Paddison, J. B. Shaw, J. E. Talbot, H. R. Thompson, R. S. Thompson, H. L. Thornton, J. C. Watt, K. S. Wilson, and H. L. Wolfe; Capts. J. T. Anderson, R. D. Chalmers, J. J. Cruickshank, J. Dawson, R. Dobson, J. S. Hollingsworth, A. C. Houghton, H. J. C. J. L'Etang, A. T. Macknight, (Miss) R. M. Marwick, S. A. Mason, R. S. McGeorge, C. N. Mills, B. B. Milstein, J. M. Scott, M. H. Sherwell, R. T. Thin, and C. R. Wright; Lieuts. A. O. Harries, M.C., and W. Mills, R.A.M.C.; Lieut.-Col. G. C. Ferguson; Majors R. Blais, H. I. Palmer, and A. E. Thoms, M.B.E.; Capts. (Acting Majors) F. S. Brien, C. C. Misener, and C. L. Pearson; Capts. T. A. Laidlaw, P. Bernstein, N. N. Levine, H. A. Roberts, and R. G. Winram; Lieut. N. A. Riley, R.C.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Surg. Lieut.-Cmdr. GERALD NOEL MARTIN, R.N.V.R., the fourth son (all of whom entered the medical profession) of the late Dr. John Wise Martin of Sheffield, died on June 30 at the age of 59, after an operation and a very short illness at the Royal Naval Hospital, Plymouth. He was educated at Sheffield and the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1913, and then held a house post at the Royal Sussex County Hospital, Brighton. His great love was for the sea, however, and he spent many years afloat, both in the Royal Navy and the Merchant Navy. In the war of 1914-18 he served throughout in the Royal Navy, and was in the water 2½ hours when the *Aboukir*, the *Cressy*, and the *Hogue* were torpedoed in September, 1914. When war in Europe broke out in September, 1939, he soon secured a transfer from the Merchant Navy, in which he had been serving, to the Royal Navy. Again he was on board a ship which was torpedoed and spent a night in a small lifeboat in the Atlantic, during which time he controlled a tourniquet on a seriously injured sailor. His service was spent in all kinds of vessels, from superbattleships to monitors, down to the *Discovery*, which was sent on an expedition to rescue Sir Ernest Shackleton. At the time of his illness he was engaged on work in connexion with the demobilization of naval personnel. He was given a Service funeral, with full naval honours. His loss is keenly felt by a great number of friends, both in the Service and out of it, nearly all of whom are members of the medical profession.

Missing, presumed killed.—Temp. Surg. Lieut. Ross McFaul Kirkpatrick, D.S.C., R.N.V.R.

Medical News

Major Basil H. H. Neven-Spence, M.D., F.R.C.P.Ed., who was re-elected M.P. for Orkney and Shetland at the recent General Election, received a Knighthood in the Resignation Honours List published on Aug. 13.

A short memorial service for Dr. Gordon Pugh will be held in the chapel at Queen Mary's Hospital, Carshalton, on Friday, Aug. 31, at 2.30 p.m.

On Aug. 8 a new kitchen suite was opened at the London Hospital, where a large basement ward has been converted for the purpose at a cost of approximately £7,000. The suite is equipped with labour-saving appointments and modern facilities for cooking, and care is taken in the presentation of food to both the patients and the staff. Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, congratulated the hospital on the lead it had given in hospital catering, and expressed the hope that other hospitals would follow its example.
